One would suppose that when over 32,000 specimens are the subject of inspection and report, it would be difficult to select the materials for a short journal article concerning them; but a very brief examination of the hall shows that the system adopted in the display enables the observer not only to appreciate the museum in its entirety, but to select the case in which he will probably find some particular object of his search.

The center of the floor space has along its length a number of flat-topped glass cases in which are displayed surgical instruments of all kinds, but in particular those intended for military service. Various miscellaneous objects are also on exhibit here. The series of microscopes is one of much interest as showing the evolution of the instrument from its earliest days. Models of military hospitals, hospital trains and steamboats bring to mind the busy days of the Civil War; while near by are tube cultures of the various bacteria the study of which has had such

a wonderful influence on the progress of surgery since those times of active service. A fine series of urinary calculi, models of the common and harmless and of the poisonous mushrooms, and life-size models of the anatomy of the horse are prominent among the objects displayed, as are also a collection of medical medals and a series of delicate longitudinal and antero-posterior sections of the human embryo prepared by Dr. Wm. M. Gray, the microscopist of the museum.

It is, however, in the display cases projecting from the side walls that the systematic methods of the museum are seen to the best advantage. In illustrating any part or organ of the human body its normal development is shown first and then the abnormal deviations that are occasionally found, with specimens from the domain of comparative anatomy that throw light on the deviations. These are followed by illustrations of its anatomy and physiology, and lastly of the diseases and injuries to which it is specially subject. The cases are numbered in arithmetical sequence. Case No. 1 and those immediately following it contain specimens illustrative of the organism as a whole, beginning with the formation of the ovule in the ovary, following its progress to the formation of the embryo in the uterus, and thereafter showing the gradual development of the latter, with many side lights on the subject from comparative embryology. The abnormal developments are then shown, such as hydrocephalus, spina bifida, extroversion of organs and various monstrosities. Next come the anatomy and physiology of the perfected system, and then illustrations of general morbid conditions such as tuberculosis, cancer, septicemia, syphilis, alcoholism, fevers, etc., and lastly general injuries, as from crushing, explosions, and exposure to heat and cold. The various anatomic regions and organs are then taken up, one after the other, and each has its medical connections illustrated by specimens showing its development, abnormalities, anatomy, physiology, morbid conditions and injuries.

In the gallery is a series of show cases, like those below, in which are exhibited the missiles, weapons, fractures, excisions, amputations and other specimens of the war. In fact, the museum of the old Ford's Theater building may here be recognized, while that on the floor of the hall is relatively a new institution. The gallery contains also many specimens of comparative anatomy, a magnificent collection of skeletons and crania, some frozen sections of the brain and dissections of other parts of the body preserved in alcohol, and many beautiful wax models of diseases of the skin.

It is, however, so difficult to convey a well defined idea of the wealth of the museum by mere written words that this article had better be closed with the suggestion that the members of the Association take advantage of the meeting in Baltimore to come to Washington and inspect for themselves.

THE forty-sixth annual session of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9, and 10, commencing on Tuesday, at 10 A.M.

## THE MEDICAL TREATMENT OF CANCER OF THE LARYNX.

Read by invitation before the Philadelphia Chapter of the Alumni Association of the Jefferson Medical College, March 12, 1895.

BY E. L. VANSANT, M.D.

ADJUNCT PROFESSOR OF DISEASES OF THE THROAT AND NOSE IN THE PHILADELPHIA POLYCLINIC; SURGEON TO THE THROAT, NOSE AND EAR DEPARTMENT OF THE HOWARD HOSPITAL; PHYSICIAN TO THE PHILADELPHIA HOSPITAL.

The medical treatment of carcinoma of the larynx, with our present knowledge is necessarily a palliative one. Still, efforts to find some drug or method of treatment that would retard or cure the malignant growth have been unceasing. Among the many remedies that have been so used may be mentioned arsenic, iodoform, ergot, mercury, sulphide of calcium, tincture of thuja occidentalis (*arbor vitæ*), chian, turpentine and condurango. Injections of pyoktanin or the anilin colors and, more recently, a 2 per cent. solution of carmine, dissolved in a 3 per cent. solution of soda. None of these have, however, stood the test of time and, although some of them do much good in improving the systemic condition and alleviating some of the symptoms, still no purely medicinal treatment has, as yet, been proved to be of curative value.

A plan of treatment that perhaps deserves fuller mention is the comparatively recent one with the toxins of erysipelas, either used alone or in combination with the toxins derived from the bacillus prodigiosus.

This treatment, which originated from clinical observations of the antagonistic action of accidentally acquired erysipelas upon malignant growths, lupus and syphilitic lesions, has been considerably experimented with, and a number of favorable results in cases of inoperable malignant growths have been reported. In the early trials of this treatment, the plan adopted was to excite an artificial erysipelas in the vicinity of the growth by making inoculations of the erysipelas streptococci. It was found, however, very difficult to produce an erysipelas by such inoculations, nor was the danger attending an attack of erysipelas a slight one. I need hardly call your attention to the fact that erysipelas of the larynx is so grave a disease, that for this form of cancer at least, such treatment would be reprehensible.

Further experimentation developed the fact that injection of the toxins derived from bouillon cultures gave quite as good results as inoculation with the living cultures, and further, that the activity of such toxins was greatly augmented by adding toxins derived from cultures of the bacillus prodigiosus.

I will not dwell upon the laboratory methods by which such toxins are obtained. At first the germs were developed in separate bouillon cultures, then filtered, a small quantity of thymol crystals being added to the filtrate, which was kept in a cool dark place until used. Later the streptococci were allowed to grow for ten days, then the bacillus prodigiosus added, and allowed to develop two weeks longer; the filtrate from this mixed culture being used. Still later, the cultures instead of being filtered were subjected to a sufficiently high temperature (58 degrees C.) to kill the germs, though not high enough to produce much chemie change in the toxalbumins. The injection of the products from this last-mentioned method are said to have a better effect than when the cultures were filtered.

Treatment by these double toxins is now carried

out by the hypodermic method. In a recently published case,<sup>1</sup> 15 minims of a solution were injected every other day, and the dose gradually increased to 40 minims. The injections may be made into the arm, leg or buttocks, and produce local redness, swelling and pain which may persist from twelve to twenty-four, or even thirty-six hours. The temperature after each injection usually rises, and may reach 103 to 105 degrees F. Nausea, chill and vomiting at times follow the injections.

This treatment has now been applied to a number of cases, and the reported results in some of them have been marvelous, the injections being followed by rapid breaking down and disappearance of the humors, and, although a large per cent. of even the greatly improved cases have recurred, still a few seem to have been permanently benefited.

I have not been able to find any record of carcinoma of the larynx treated by this method, but several cases of sarcoma involving the tonsils, palate and part of the larynx have been reported as successfully so treated, the growth largely disappearing, and the general condition of the patient greatly improved.

For much of our recent information, and for most of the experimentation with this treatment in this country, we are indebted to Dr. William B. Coley, of New York, who has formulated the following conclusions in regard to it:<sup>2</sup>

1. The curative action of erysipelas upon malignant tumors is an established fact.
2. This action is much more powerful in sarcoma than carcinoma.
3. This action is chiefly due to the soluble toxins of the erysipelas streptococci, which may be isolated and used with safety and accuracy.
4. This action is greatly increased by the addition of the toxins of bacillus prodigiosus.
5. The toxins, to be of value, should come from virulent cultures and should be freshly prepared.
6. The results obtained from the use of the toxins are so nearly, if not quite, equal to those obtained from an attack of erysipelas that inoculation should rarely be resorted to.

In spite of the very favorable opinion of the curative action of erysipelas upon malignant tumors, expressed by Dr. Coley, it is my conviction that, as yet, the results of the erysipelas treatment are not sufficiently successful to warrant its preference in laryngeal cancer, over early and thorough surgical procedure, and that at present its use should be restricted to cases that may be termed inoperable.

The medical treatment of laryngeal cancer being then largely a palliative and symptomatic one, we will consider the treatment of the different symptoms, and when we reflect that so many of the cases when seen by us are inoperable, and that a large per cent. recur after operation, it will be seen that such symptomatic treatment is of the greatest importance. By it we may, at least, hope to alleviate the patient's suffering and prolong his life.

For the purpose of better considering the medical treatment, I will divide the cases of cancer of the larynx into two classes or groups: The first class comprises those cases beginning at some point outside of the larynx proper, it may be the tonsils, base of tongue, pharynx, esophagus, or even the thyroid

<sup>1</sup> New York Medical Record, No. XLVI, 1894.

<sup>2</sup> The Journal of Laryngology, Rhinology and Otolaryngology, vol. IX, No. 1, page 51.

gland, and then later extending into and involving the larynx; such cases are termed extrinsic or pharyngo-laryngeal. The second class will comprise those that begin within the larynx itself and are termed intrinsic or endo-laryngeal.

In the first class, the pharyngo-laryngeal, painful and difficult deglutition, slobbering of saliva, and pain, which also radiates to the ear, are apt to be the earliest and most urgent symptoms; while dyspnea, loss of voice, cough, etc., may not be present until late in the course of the disease.

In the second class, the endo-laryngeal, dyspnea, dysphonia and cough are apt to be the first symptoms, and dysphagia may not occur until the growth extends to the surrounding parts.

As regards the treatment of dysphagia, if ulceration be present, treatment addressed to the healing of such ulcers is indicated. This will consist of careful cleansing of their surfaces by means of antiseptic washes or by swabs moistened with disinfecting and cleansing solutions, such as hydrogen dioxid, weak solutions of carbolic acid, permanganate of potash, etc. After thorough cleansing, the surface of the ulcers may be touched with nitrate of silver in solution, or dusted with iodoform, calomel or other detergent powders. Recently I have had good results from the use of acetanilid; with it not only have the ulcerated surfaces been reduced in size, but considerable relief from pain has been obtained. Cleansing the throat with warm alkaline sprays or washes, and applying solutions of cocain, by means of sprays or swabs some five to ten minutes before eating, will often so relieve the dysphagia, that the patient may enjoy a fair meal. We begin preferably with a weak solution of the cocain, say 2 per cent. to 4 per cent., and increase the strength of the solution as found necessary; frequently we must resort to solutions of 10 per cent. or even stronger in order to obtain the desired local anesthetic effect.

Insufflation of morphin, or morphin mixed with the subnitrate of bismuth, powdered starch or other such excipients will give some relief from pain and permit of swallowing. Dusting the throat with powdered formanilid or swabbing with a 10 per cent. to 20 per cent. solution of the same is said to produce a considerable local anesthesia which is quite lasting.<sup>3</sup> At times it will be found necessary to resort to rectal feeding, the patient not swallowing anything but the necessary fluid. Rest thus given to the throat for a few days, especially when associated with appropriate local treatment, may greatly relieve the dysphagia.

A procedure that I have frequently advised, and which is usually attended with marked success, is for the patient to place a glass of milk or broth on the floor, or upon a low stool, and then lying prone upon a lounge to suck the fluid up through a tube. At times the patient has found that by sitting in a chair and placing the glass upon the seat of a chair in front of him, he could by leaning forward swallow the fluid through a tube very comfortably. With the appearance of dysphagia the patient should confine his diet to semi-solid and fluid foods. Efforts to continue the deglutition of solids will lead to increase of the difficulty, and hasten the tendency to the inflammation and ulceration. Food should be predigested by the addition of peptonizing powders. Peptonized milk is especially useful. Raw eggs can usually be

swallowed even when the dysphagia is severe. Sucking of ice pellets is grateful to the patient. The use of the esophageal tube for feeding is attended with the danger of accidentally perforating the esophagus, and if resorted to, should be used with great care. In cases involving chiefly the tonsils and base of tongue, feeding through the nose may be practiced, peptonized fluids being passed to the back of the pharynx through tubes introduced through the nostrils.

Dyspnea as a symptom is usually an early one, particularly so in the endo-laryngeal cases, and even in the pharyngo-laryngeal group may be noticed before dysphagia. For the treatment of this symptom, rest will be found to be of great value, for even comparatively slight exertion greatly increases the embarrassment to the breathing. At times the dyspnea is associated with and chiefly due to the accompanying edema of the glottis. Here applications of a 20 per cent. oily solution of menthol, inhalations of steam vapor medicated with benzoin, chloroform, menthol, etc., may be used. Scarification of the edematous parts with the laryngeal lancet should not be delayed, but should be performed early; such scarification may be followed by endo-laryngeal application of menthol solutions, inhalation of medicated vapors, the continuous use of the cold coil around the neck, and the administration of pilocarpin as necessary.

When the dyspnea is due to mechanical obstruction caused by the growth; preliminary to the medical treatment, removal of part of the growth may give marked relief both to voice and respiration. Tracheotomy, even, must at times be resorted to. If the pressure is against the trachea, the position of the patient may have an influence upon the dyspnea; the patient will soon find in which position he is the most comfortable, and should be encouraged to remain so. Strychnin seems to give relief in certain cases.

Aphonia must be treated upon the same plan as the dyspnea. Hoarseness is usually a very early symptom, and the patient should give the vocal organs as much rest as possible. Sedative inhalations can be used here with advantage. The following formula can be recommended:

R. Tinct. benzoini compositæ.  
Tinct. opii camphoratæ . . . . . aa fʒi.  
Chloroformi . . . . . ℥ xx.

M. Sig.: Add a teaspoonful to a pint of water at 150 degrees F. and inhale vapor.

The medicated hot water is to be placed in a pitcher or bowl inclosed with a funnel-shaped paper or a folded towel. Vinegar and paregoric, a dessert-spoonful to a tablespoonful of the former with one-half teaspoonful of the latter to a pint of water at 140 to 160 degrees F. and inhale vapor.

R. Acid acetici . . . . . ℥ xxx to xlv.  
Tr. opii camph . . . . . ℥ xv to xxx.

Mix and add to a pint of water at 150 degrees and inhale.

Where obtainable a steam atomizer can be used to make these medicated vapors, or the medicine may be placed upon a sponge in a bottle which is placed in hot water. Nebulized balsams can also be recommended. Strychnin is also valuable in dyspnea and may be used hypodermically.

Pain which is a most constant symptom is usually of an acute, lancinating character, and is often reflected to the ears. For its relief, applications to the larynx of morphin, cocain, iodoform, acetanilid, etc., may be used. Warmth applied to the neck

<sup>3</sup> Medico-Medizinische Presse, 1893. No. 10.

gives some relief, as do ointments and liniments containing belladonna, chloroform and aconite applied externally. Hot instillations into the ear of pure water, or warmed solutions of cocain, morphin, atropin, etc., dropped into the ear, aided by hot moist or dry external applications give relief to the severe earache.

Cough may not be so prominent a symptom as to demand special treatment. The sedative inhalations of benzoin (compound tincture) associated with laudanum, chloroform or conium or the local applications of morphin, and cocain usually give relief. If necessary, morphin and codein may be given internally. For the excessive saliva, antiseptic and astringent mouth-washes and gargles, or the administration of a small amount of atropin may be recommended.

The general symptoms associated with cancer of the larynx are those usually found in malignant cachexia. Rest, abundant feeding and fresh air are needed. Constipation being the usual condition must be relieved by enemata or mild cathartics. Avoidance of tobacco and ardent spirits is important, not only for the general condition but also on account of their local irritating effect. The same may be said of impure or dust-laden air. The patient should be in a pure fresh atmosphere as much as possible, and if exposed to dust or impure air should breathe through a respirator. Arsenic, cod-liver oil, iron and tonics are indicated. The mild Zittman's decoction of sarsaparilla has been recommended. In the later stages, anodynes give great comfort to the patient; the hypodermic use of morphin, or morphin with atropin is usually the best method to administer them.

A treatment that is more of a surgical nature, but which should only be intrusted to the skilled hand of the laryngologist, is the attempt to destroy the growth, or relieve urgent symptoms by intra-laryngeal operation, and more particularly by the use of the electric-cautery. When the growth is quite local, and there is no infiltration of the adjoining lymphatics, good results may be expected from a thorough destruction of the growth and the surrounding tissue by intra-laryngeal methods; such destruction may be best performed with the electro-cautery, or the use of the cautery after the removal of the growth with the laryngeal knife or forceps.

In advanced cases with much infiltration of the surrounding parts, intra-laryngeal removal of parts of the growth may prolong life and lessen the severity of the symptoms quite as much as can be expected from extra-laryngeal operations in such cases.

Following such intra-laryngeal destruction of small local growths, or after the graver operations, medical treatment upon the lines already laid down must be continued for some time in order to obtain good final results.

#### THE EARLY SYMPTOMS, DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS OF CARCINOMA OF THE LARYNX.

Read by invitation before the Philadelphia Chapter of the Alumni Association of the Jefferson Medical College at a meeting held March 12, 1895.

BY WILLIAM S. JONES, M.D.

CHIEF OF NOSE AND THROAT DEPARTMENT JEFFERSON HOSPITAL.  
CAMDEN, N. J.

There is nothing in the development of laryngeal cancer which gives rise to symptoms differing in any notable way from those which characterize the onset of a benign growth. Impairment of the voice is the

first symptom which manifests itself, and even this may be absent for a considerable period, especially in those cases that begin in the ventricular band. There, then, as the infiltration increases, the voice becomes weaker until there is complete aphonia.

Probably the next symptom to develop is dyspnea. Particularly is this so, if the case is entirely intrinsic, while in the case of an extrinsic cancer, dysphagia may develop owing to the mechanical obstruction in the esophagus. As a direct result of this condition, salivation becomes a prominent symptom in a large proportion of the cases.

As regards the involvement of the lymphatic glands of the neck in cases of intrinsic cancer; as long as the growth is confined to the larynx proper, there is no glandular enlargement. This is almost without an exception. While in extrinsic growths or those which involve the epiglottis, the ary-epiglottic folds or the arytenoids, glandular involvement is an early symptom at about four or six months. Then about this time new symptoms develop. The most important is ulceration and hemorrhage.

Ulceration is due, in part, to attrition to which the growth is subject in the functional movements of the parts, but more undoubtedly to the increased cell proliferation, which occurs with its increased size. Before ulceration sets in the secretions while increased, are comparatively normal, and may give rise to a slight irritation and perhaps cough. After ulceration sets in the secretions become somewhat excessive, and consist of necrotic tissue and pus cells. At the same time a characteristic odor of cancerous ulceration becomes apparent in the patient's breath. This is decidedly fetid, and is usually recognized by a peculiar musty smell. Sometimes the first suspicion of cancer may be excited by this odor. These are all of the early symptoms of a malignant growth of the larynx, excepting pain which is not a constant symptom, and in some cases it is actually absent. It is more prominent in extrinsic cancer than in intrinsic. It is sharp in character, and usually radiates toward the ear.

In diagnosing a case you have to consider heredity, sex and age. Heredity exercises the same influence in laryngeal cancer as in any other region of the body. It occurs principally in the later years of life; and is much more frequent in the male than the female.

On laryngoscopic examination there is nothing in the general appearance of carcinoma in its earlier stages which renders it possible to make an absolute definite diagnosis; this is the time when the patient first complains of an impairment of the voice. Impaired motion of non-paralytic character leads to a suspicion of malignant infiltration, especially if any evidence of infiltration is apparent. A few months from this time the laryngoscope will show to the trained eye a thickened mass; irregularly outlined, soft in consistency, in color about the same as the healthy portion of the larynx, and with a broad base. As the case advances from this stage the diagnosis becomes easy. The voice becomes gradually aphonic, owing to the increased tumefaction, for it is to be borne in mind that the disease consists in a cell infiltration which burrows broadly and deeply into the surrounding parts. The growth gradually enlarging, encroaches on the lumen of the larynx. The progressive development of all symptoms, together with the lancinating pains shooting toward the ear, and

the cachexia with the glandular enlargement in the very late stages, should enable one to recognize the true character of the disease.

In the differential diagnosis, there are three affections of the larynx that produce impairment of the voice which can be distinguished from cancer without the use of the laryngoscope, viz., acute and chronic laryngitis and nervous aphonia. Acute laryngitis, by the sudden loss of the voice. The chronic, by the difference in the tone. In some portions of the day the voice is almost normal, while at another time in the same day, the voice is aphonic. This will also occur in some benign growth such as polypus, which has a pedicle. This growing above the cords, while remaining in that position causes little or no hoarseness; but occasionally it will drop down between the true cords and while there causes complete aphonia.

In hysterical aphonia the voice is lost, and the patient simply communicates in a whisper; there is no break in the tone. In all other cases of impairment of the voice, you will have to depend upon inspection of the larynx. By the laryngoscope all forms of paresis of the larynx can be eliminated, for in these cases there is no tumefaction, the aphonia being due to a fixed position of one or both true cords. By the same means all benign growths can be readily distinguished; their color, shape and general outlines differ from a malignant growth; also a benign growth springs from the surface or mucous membrane, and does not cause an increase in the size of the part from which it grows, or cause surrounding inflammation or infiltration. This leaves two affections yet to consider, and are the two from which it is difficult to make a diagnosis. These are tuberculosis and syphilis of the larynx. Tuberculosis occurring the most frequently we will consider first.

The first symptom we have is an impairment of the voice, cough, with increasing symptoms as the case advances. The first manifestation in the larynx is unilateral. The most frequent site of primary invasion is upon the arytenoid cartilage or commissure; the next, ary-epiglottic fold and epiglottis. A moderate amount of tubercular infiltration seems to cause a certain amount of tumefaction, which interferes with circulation, producing a moderate amount of edema with a dull gray color, and profuse secretions. When existing, there are two positive conditions in tubercular laryngitis that can not be mistaken for any other affection—the turban-shaped epiglottis and the club or pyriform arytenoids—these conditions are not caused by any other affection, but unfortunately they are frequently absent. The ulceration of tuberculosis is not a deep ulcer, has a ragged uneven edge—worm-eaten as it were—difficult to detect the outlines; hemorrhage unusual; the whole larynx becomes anemic.

The larynx may be invaded by any form of syphilis, from the primary lesion to the deep ulcer of the later stages. The usual affection is the third stage, and of that we will speak. Impairment of the voice is the first symptom; pain in this affection depends on the location of the lesion. If the soft parts only are affected the pain is not marked. If the epiglottis or posterior portion of the arytenoids is the seat of lesion, the pain is great on swallowing.

In the superficial ulcer of syphilis we have a distinctly yellow purulent discharge, a slightly rounded elevation without swelling. In the deep ulceration,

we have all of the features of the superficial ulcer exaggerated, with its sharply cut edge, a marked injected areola surrounding it, and a profuse discharge of pus and necrotic tissue.

When a gummy tumor forms in the larynx, whether single or multiple, we are in doubt as regards the diagnosis. This presents itself in the form of a smooth, symmetrical, rounded tumefaction, which is ordinarily covered with healthy mucous membrane; it appears somewhat suddenly, and when it has attained its full size remains stationary unless ulceration occurs. This may occur in any portion of the larynx and varies in regard to size. The rapidity of the development of the growth, together with the subjective symptoms and the clinical history should give rise to a suspicion of syphilis, but by inspection of the larynx we may not be able to make a definite diagnosis. The administration of iodid of potassium will, in a few days, determine whether we have a gummy tumor to deal with. This is a test that all laryngologists will often be compelled to resort to before a decided opinion is given.

In summing up, we have as distinguishing points, the age of the patient, tubercle occurring early and cancer late in life. In the very large majority of instances, a tubercular process in the larynx succeeds or accompanies a similar process in the lungs.

Heredity exercises the same influence in laryngeal cancer as in any other region of the body, and on inspection we have in lupus the irregular contour, highly injected membrane but no ulceration, no secretion of pus and no exfoliation of necrotic tissue.

In sarcoma, we have a distinct tumor with, perhaps, an eroded surface, but no distinct ulcerated surface with pus secretions.

In carcinoma, we have a hard nodular tumor, with a ragged ulceration, the edges of which are not sharp cut, a tendency to slight hemorrhage and no well-marked areola.

## CHRONIC GASTRITIS AND ITS TREATMENT.

Read before the Louisville Academy of Medicine, April 1, 1895.

BY W. CARROLL CHAPMAN, M.D.

EDITOR "MEDICAL PROGRESS;" ASSISTANT TO THE CHAIRS OF CLINICAL MEDICINE AND CHEMICAL PHYSIOLOGY, KENTUCKY SCHOOL OF MEDICINE, LOUISVILLE, KY.

We have to-night for consideration "one of the best nourished and most widely prevalent diseases in the world." The subject is too large to review in all its details, in a paper that would interest the members of this society, and it will only be my aim to present a synopsis, hoping that the discussion, by those interested, will bring out the most salient points. This subject could scarcely be introduced without some reference to the abuse of the terms, dyspepsia and indigestion, by the medical profession in general. We who pretend to be precise in our technical phrases would be highly amused at our antiquated brother who talks of "lung fever" and "the dropsy" or the "weed in the breast," to his reverential hearers with all the wisdom of a "Sir Oracle." Yet we precise men walk into the sick chamber, feel the pulse, look at the tongue, get the subjective symptoms and with the most profound gravity answer the patient's query: "Oh, you have a case of indigestion," and prescribe pepsin or pancreatin or such. How horrified we "higher standard of medical education" men would be to hear our professional brother tell the mother, in answer to the question as to what was the

trouble with her child, say, "O, he's sick," and yet this response would have just as much meaning and be just as concise in its application in this instance as the term indigestion applied to some disease of the gastro-intestinal tract. Dyspepsia and indigestion are not diseases but symptoms of disease.

We only refer to such methods in order to arouse the interest of the profession in this large field of special work, hoping that they may either acquaint themselves with it properly or place it in the hands of those who are capable of diagnosticating this large variety of diseases in a scientific manner.

*Etiology.*—The causes of chronic gastritis are very numerous. It may result from the acute and sub-acute forms when they are frequently repeated. Irritants act more readily when the mucous membrane has been altered by changes in the circulation or the condition of the blood, the mucous membrane thus being rendered more sensitive than it is normally. These changes in the circulation may be produced by all processes which lead to venous congestion of the stomach; such as affections of the liver, spleen, heart and lungs. Tuberculosis, also of the kidney and uterus.

Chronic gastritis may be caused also by direct local irritation as a consequence of cicatrices and neoplasms or irritating substances which are brought in contact for a long time with the gastric mucous membrane as large, half-digested and insufficiently insalivated morsels of food, or from putrid material in the mouth, due to carious teeth or inflammation of the gums, or the muco-purulent matter from pharynges being swallowed. To this category also belong tobacco juice, concentrated alcoholic beverages, condiments; also toxic substances, like trichinæ and larvæ. Then there are certain causative elements which circulate in the blood and are excreted in the stomach; for example urea and the products of intestinal putrefaction. Of the above etiologic factors the most important are those irritating substances taken into the stomach.

*Pathology.*—The mucous membrane has a yellowish-gray or slate-gray color, it is usually thickened and covered with a delicate layer of mucus. The portion of the stomach usually involved is the pylorus, but may be the entire mucous membrane. The sub-mucosa and muscularis may also be thickened and the latter especially at the pylorus may cause hypertrophy with consecutive stenosis. The minute anatomy of the process is that of a parenchymatous and interstitial inflammation. The glandular cells are in part destroyed, partly granular and partly shriveled. The superficial layer of the epithelium of the mucosa is loosened and is sometimes found in the wash water after lavage.

As the disease advances it finally causes retrogressive changes in nutrition, which are at first manifested in a progressive fatty degeneration of the glandular cells, and which finally cause complete atrophy of the mucous membrane, a point emphasized by Lewy, which must finally lead to a total destruction of the secreting parenchyma with all its consequences. The process progresses from above downward, and first obliterates the orifices of the ducts. The stomach as a whole is enlarged; its walls appearing thinned.

Another form of anatomic change is characterized by a marked activity of the interstitial connective tissue and leads to its hypertrophic prolifera-

tion, which proceeds from the base of the glands upward toward the lumen. Finally, the parenchymatous cells having been deprived of their nutrition, undergo atrophy. Here the organ is not enlarged *in toto*, but at times may be small and cirrhotic.

Another change arises from the villous outgrowths from between the small depressions in the gastric mucous membrane; this gives rise to the polypoid outgrowths from it, usually the size of a milium to a pea, and arranged alongside of one another in large numbers.

*Clinical History.*—Chronic gastritis presents itself in two clinical forms which are easily differentiated; chronic simple gastritis and chronic mucous gastritis. The differentiation really depends on the results of the chemic examination of the stomach contents. The patient usually complains of a dry, pasty or salty taste which is often communicated to the food during mastication. The tongue is usually coated at the base, where the reddened, swollen papillæ project above, while the edges bear the impression of the teeth. The lips are usually dry and chapped. Belching is very frequent; the gas being either odorless or having an effusive, sour smell and disagreeably rancid taste. It is frequently accompanied by the regurgitation of the gastric contents, having a sour and disagreeable taste; these regurgitated masses often imparting a burning and scratching sensation along the esophagus. When this is limited to the lower portion of the esophagus it is termed cardialgia.

When these sour regurgitations occur it is important to distinguish sharply between those due to the products of fermentation—namely, acetic, fatty and lactic acid, and such as owe their taste to an over secretion of hydrochloric acid, the former condition indicating chronic gastritis and the latter being classed with the gastric neuroses.

Vomiting is an irregular occurrence. I have noticed numerous writers in periodical literature mentioning vomiting as an attending symptom of chronic gastritis; but such is not the case. Nausea is a much more frequent symptom.

Shortly after eating there is a sense of oppression or a "bloated feeling" with slight soreness in the epigastrium; the latter becoming a pain only on pressure. The patients frequently complain that the food remains abnormally long in the stomach, and such may really be the case when these conditions are combined with weakness of the gastric muscular wall—atony of the stomach. The latter condition permits decomposition to take place in the ingesta; the carbohydrates ferment; the albuminoids putrify. This may really lead to a true gastrectasis.

Constipation generally exists. Occasionally diarrhea and constipation alternate.

The patients have the sensation that the evacuations are incomplete and suffer much from flatulency and rumbling in the abdomen.

We notice a diminution of mental activity, disinclination to bodily exertion, languor during the day, headache or a feeling of oppression in the head, and a morose, irritable disposition with a feeling of heaviness in every limb. Sleep is deep and long but not refreshing. Just here permit me to say that I have very little confidence in the so-called cases of "walking typhoid fever," and believe that the true condition of these cases is one of a low form of chronic

gastritis in which retrogressive changes in the nutrition of the stomach itself have taken place.

A peculiar condition first described by Trousseau is the *vertigo gyrosa* or gastric vertigo. I have now under my care a lady who suffered from frequent and severe attacks of vertigo due to chronic gastritis. These would occur without the loss of consciousness at almost any time. For a while she could not incline the head forward at all without one. Then they have come on while in bed; "the room whirling around and the ceiling moving," as she said, until she would cry out with fear. These symptoms have almost entirely left under hydrochloric acid, strychnia and lavage.

The first stage of chronic gastritis is atrophy of the mucous membrane or anemia of the stomach, *i.e.*, a condition in which complete destruction of the glandular parenchyma has taken place and has been designated as *phthisis mucosa*. After a time so severe a disturbance of the nutrition is developed that the patient dwindles away and finally dies of marasmus.

**Diagnosis.**—We have, first, to differentiate chronic gastritis from other diseases and then to distinguish one variety from another. Idiopathic gastritis can only be diagnosed after ulcer, carcinoma, dilatation, neuroses or the acute gastric disorders have been excluded, and this after a careful examination with the aid of all our modern diagnostic resources. Our only positive means of diagnosis is the examination of the stomach contents. It has been found best to make this examination after the patient has taken what is called the test breakfast. Ewald's test breakfast consists of a roll and a cup of coffee. It seems to me better to substitute water for the coffee. The gastric contents are obtained from one to eight hours after the meal, according to what we wish to test for. For instance, the secretion of hydrochloric acid is at its height about one hour after eating. At that time in simple chronic gastritis we find the amount of hydrochloric acid lessened. Pepsin and rennet are small in amount, but form propeptone and peptone; usually contain lactic and fatty acids. The mucous form differs from the simple in the abundance of mucus present so that acetic acid gives a marked mucin reaction, acidity always low. Hydrochloric acid usually absent. When atrophy has taken place the stomach contents contain after the test breakfast, neither mucus, hydrochloric acid, pepsin or rennet. Where there is muscular weakness of the gastric wall it is determined by the salol test.

The chemic differentiation of carcinoma and atrophy where there is no tumor, swelling of the lymphatic glands, cachexia or hematemesis is more difficult. Ewald refers to one important point, namely, the bloody color of the stomach contents due to the presence of altered blood pigment.

**Prognosis.**—Chronic gastritis is a disease of long duration. Even when the disease is apparently cured the organ is left so sensitive as to predispose to a fresh attack. Then the disturbances of nutrition and the consequent deterioration of the tissues render the system less resistant toward other poisons particularly tuberculosis. To make the chemic diagnosis more plain let us briefly rehearse the tests. Say we have the stomach contents from a patient suffering with chronic gastritis.

We first filter, then, with blue litmus test for acidity. It may turn either red or present no change. If it

turns red we next test for the kind of acid. We use Congo paper knowing that if free hydrochloric acid is present we will get a sky-blue color. In this case there is no change. We try again with Gunzburg's reagent by placing a few drops of filtrate on a porcelain dish, then adding the reagent and heat. If HCl this will turn bright red. Still no change. Then we test for lactic acid with neutral ferric chlorid solution and find it present by the deep canary color given by heat. If butyric acid is present this same reagent gives a tawny color. If the stomach secretes pepsin and rennet we will find here peptones and propeptones indicated by an intense purple red on the addition of cupric sulphate, the so-called biuret reaction. For the motility we use the salol test, and for the absorptive power the iodine and starch test of the saline and acute articular rheumatism. Ewald says that a large number of the cases which are usually said to have died of old age perish from gastric atrophy.

**Treatment.**—In the treatment of this disease we should endeavor to replace the deficient supply of gastric juice; stimulate the depressed functions of the organ and counteract the irritant substances introduced from without. The administration of hydrochloric acid not only replaces the deficiency in this secretion, but it prevents organic fermentation, thus filling two offices at once. It should be given to its chemic effect. Usually 10 drops after eating, in as little water as the patient will tolerate and if necessary repeated two or three times at intervals of fifteen or twenty minutes.

Pepsin should only be administered in those cases in which its absence can be positively proved, and then dissolved in a solution of hydrochloric acid fifteen to twenty minutes after eating. We doubt the efficiency of pancreatin and have had no occasion to use papoid.

To stimulate the activity of the organ, lavage stands pre-eminent, except when dilatation has taken place. The douche should be combined with this; *i.e.*, after the wash water runs clear, a quantity of medicated solution may be left behind. Caution must be used in this, as serious toxic effects have been reported.

Lavage not only stimulates the gastric functions, but removes the irritant substances which would otherwise lie in that viscus and decompose or ferment, thus aggravating the disease.

It has been proved that chlorid of sodium in the blood increases the secretion of gastric juice.

Nux vomica has excellent claims for this purpose, also the bitters, quassia, gentian, etc. The carminatives are abused in this respect. The regulation of the diet and mode of eating require the most careful attention of the physician, but these would furnish separate chapters in themselves. So with the use of the numerous mineral waters. Carious teeth should be removed. The bowels which are nearly always constipated must be kept open. As the disease nears a cure this symptom gradually leaves. In this connection I wish to call attention to the most excellent results I have obtained from the use of one or two drop doses of Fowler's solution one hour or so before each meal. The mode in which it acts I do not know, but possibly by stimulating the secretions, gastric and intestinal.

Finally, out of door exercise in this, as in the successful treatment of all chronic diseases plays a most important and excellent part. Of the agents employed for this purpose the bicycle for either men or women is the one *par excellence*. It develops the mus-

cles, stimulates the secretions, furnishes the best means of oxydizing and enriching the blood and to a great extent overcomes the constipation.

## DISCUSSION.

DR. J. B. MARVIN—The essayist has presented this interesting subject so clearly and with such easy diction that I fear he has glided over some of the points without emphasizing them enough. There are one or two points as to the causation; I believe he mentioned all save one. Certain conditions of the buccal and naso-pharyngeal cavities are frequent causes of chronic gastritis, and the latter will not receive benefit until the naso-pharynx and mouth have been put in good condition. I think that the naso-pharyngeal catarrh causes chronic gastritis often and not the reverse as believed by many. The essayist said nothing of the various bacteria found in the stomach and they may cut a figure in these cases. A case should never be classified until we have examined other important organs, heart, liver and lungs, and especially the kidneys. Chronic interstitial nephritis is a most frequent cause of gastric catarrh. Diabetes frequently causes gastric catarrh. It has been my misfortune to see cases who came for treatment of their stomach trouble and who had sugar in their urine. Another point is, I doubt if any case of chronic gastric catarrh fails to present evidences of malnutrition. There is a close connection between the stomach and bowel. I always put the question, and generally answer it in advance, if there is constipation, and a gastritis does not improve until the bowels are improved. They go hand in hand. I think a line should be drawn between gastric catarrh and the so-called nervous gastritis or gastrectasis. We frequently see most marked reflex nervous symptoms in chronic gastric catarrh. Those who have read Bouchard on "Auto-Intoxication," and those who have not, will be repaid by doing so; will remember he accounts for these nervous phenomena by auto-intoxication. The essayist said nothing of the chemic tests which we use in all cases at the Kentucky School Dispensary. These are best applied after a test breakfast has been given, consisting of tea, without milk or sugar, or warm water may be substituted, with a roll; or we can use this test breakfast alone and it tells us a great deal. In acute gastric catarrh the pain comes on quickly. In chronic gastritis if due to a hypersecretion, it comes on several hours after, and if due to deficient secretion we have pain, a sense of weight and fermentation. As to treatment we hardly know what to do. We begin to question whether the stomach tube does good or harm. It makes them think of their stomachs, and they may begin to use the tube themselves to their own detriment. But it is an excellent remedy; the benefits are so quick and striking that it forms a valuable part of our treatment. It is not well to pet the stomachs with peptonized milk and predigested foods; they do more harm than good. The stomach must be made to work; it needs a stimulant and exercise as it is degenerated. One of the hitters not mentioned and which far surpasses all others in my estimation is condurango. It is used in a fresh infusion. These cases need muriatic acid, and nearly all will object to acid; they complain of sour stomach, and can not understand why they must take acid, and one has to resort to all sorts of devices to make them take it.

DR. J. B. BULLITT—I wish to say a word in regard to exercise of the stomach. A rather singular method which I have heard of from one source is this: You take a stomach tube open at the end, and not at the sides, and pass it into the stomach. When the end reaches the stomach, a contraction is caused, and a gush of fluid takes place; if the tube is withdrawn slightly and again pushed in, another contraction is produced. This procedure is called, gastric gymnastics; chronic atonic conditions of the stomach and dilatation are said to be much benefited by these gastric gymnastics.

DR. CHAPMAN—I am glad Dr. Marvin emphasized two points; one that chronic gastritis is caused by naso-pharyngitis. I did not lay sufficient stress upon it. The nose and throat men are inclined to think that the pharyngitis is caused by the gastritis. As to the impression that lavage can prove harmful, I can heartily concur in that. It is a treatment which gives more relief, and comes nearer curing than any other agent that I know. But it does harm to continually introduce it as is done if the patient has one himself. As to the point mentioned by Dr. Bullitt in regard to stomach gymnastics, I always use a tube open at the end, and I nearly always fail to obtain the stomach contents, unless I have the patient press on his stomach or gag or cough. This is perhaps due to the tube being soft and compressible.

DR. J. M. RAY—I am sorry not to have heard the paper but I wish to speak of one point I heard in the discussion. That is in regard to naso-pharyngitis in relation to gastric diseases. I can not agree with the statement that so-called chronic naso-pharyngitis produces often chronic gastric disturbances.

There is only one form of muscular naso-pharyngeal disease accompanied by an increased secretion from the mucous surfaces, and that is acute coryza. The chronic form it is claimed by Bosworth, interferes with the function of the mucous glands and by hypertrophy obstructs drainage. So that secretions may become obstructed in the drainage and while there is apparently an increase of secretion there is really a diminution. The normal secretion is said to be about 1 per cent. in twenty-four hours. There is a red roughened granular condition found often in the pharynx that I believe is the result of gastric disturbances, but I can not see how nasal disease causes disturbances in the stomach. The idea seems quite prevalent especially among the laity that most of the ills of mankind are due to nasal catarrh. We all know that the great majority of nasal diseases are found to be due to local changes in the nose.

DR. CHAPMAN—In washing out stomachs I have found frequently, large quantities of muco-purulent material, often almost crusts, especially in the young who have naso-pharyngitis, who swallow it while asleep. These when in the stomach neutralize the stomach secretions, irritate the mucous membrane and undoubtedly cause chronic gastritis.

## ACUTE NEPHRITIS IN AN INFANT.

Read before the Chicago Pathological Society, Jan. 14, 1895.

BY ELIZA H. ROOT, M.D.

CHICAGO.

Mother's history: A. B., age 19, unmarried, primipara, admitted to Chicago Hospital for Women and Children, Jan. 25, 1894. Urine albuminous; legs edematous; purulent leucorrhea and urethritis. Specific taint denied. Albuminuria and edema disappeared under milk diet and Basham's mixture, and leucorrhea controlled by salicylic acid injections. Child born February 26, after a normal labor lasting twelve hours. February 27, decided albuminuria with puffiness of lids, which latter soon disappeared, the albuminuria, however, continuing for four or five weeks. On the tenth day temperature rose to 103 degrees F., from mental excitement over her child's condition, but promptly fell to normal. Mother left hospital March 13 in good condition except that the uterus was still large and congested. Her occasional visits to the dispensary for six weeks enabled me to confirm the absence of syphilis.

Infant's history: Male, weight nine pounds, well developed, urination from the first manifestly somewhat difficult and painful. The fourth day temperature rose to 102.5 degrees F., attended with incessant crying, and the appearance of a papular eruption, mainly on the neck and face. About the tenth day temperature rose to 103 degrees and later 104.5, only slightly reduced by wet pack or bath. Skin became dry and branny with fissures in axilla and groin and about wrists and ankles. During the last two days of the illness the temperature fell to normal and then to 96.5 degrees. Bowel movements became thin and greenish; eclamptic convulsions appeared and then paralysis of left leg. The child gradually became comatose and died March 10.

Post-mortem findings: kidneys were swollen and full of blood, presenting the appearance of acute inflammation. The vena cava ascendens, beginning at or near the junction of the renal veins was filled with coagulated blood having all the appearance of an ante-mortem thrombus. This thrombus was followed into the left common iliac, into the external and internal iliacs, thence to the deep and superficial

veins of the thigh and readily traced into their smaller tributaries. The presence of this thrombus accounts for the paralysis of the limb and the watery semi-transparent whiteness of the foot. The umbilical vein and arteries presented nothing unusual; liver and spleen large and filled with blood; lungs congested; pericardial sac filled with straw-colored fluid; no evidence of cardiac inflammation. Veins of the brain and its membranes contained dark blood but no thrombi. Ureters and urethra patent and normal; bladder empty; stomach and intestines normal; thyroid and thymus glands normal. Perirenal fat absent or nearly so, while subcutaneous fat was present in a very small degree. Microscopic sections of the kidney have been kindly made for me by Dr. Latham, who will present them for the inspection of the Society. They show the changes of a subacute nephritis. The question that has presented itself to my mind in considering the cause of renal disease in this case is, Was the disease due to septic infection, and, if so, how did it occur? The mother was unhealthy, as her history shows. She was considered an unclean case and extra precautions were taken against further infection. She was isolated, during the lying-in, to the extent of being assigned to the care of one nurse who cared for her and her child only. I can not disabuse my mind of the idea that the infective matter still remained somewhere in the parturient canal and that infection took place through the umbilical cord.

NOTE.—Since I read this paper I have seen two infants, hospital cases, in which I made the diagnosis of renal inflammation, acute; one a boy, the other a girl. Both infants presented symptoms similar to those described in the case reported, but not so severe, as both babies recovered. The dryness of the skin, its cracking in the creases of the flexures and the temperature were nearly the same as in report, except that recovery began when temperature reached normal. In the case of the baby girl we obtained enough urine to test for albumin and found it abundant, but not enough to determine quantity per volume. Both children were very ill. I expected both to die, especially the girl, as she was worse than the boy. The mother of the little girl was not so well generally as the other, and at one time, prior to delivery, had a small amount of albumin in urine. The other mother seemed quite well. Both had a normal lying-in and left the hospital well, the babies still showing the effects of their illness but bidding fair for full recovery. Both babies showed stigmata of faulty development in the bones of the head and the ears. Mothers presented no similar signs.

#### DISCUSSION.

DR. G. H. WEAVER—Dr. L. Emmett Hall, of New York, has written two articles on primary nephritis in infants. The first appeared in 1887; at that time he had collected from his own practice and that of his friends during eighteen months, eight cases of what he called primary nephritis in infants, whose ages varied from 2 days to 2 years. From the literature he collected eleven more, making nineteen cases. He concluded that primary nephritis in infants is not a rare disease, but that it occurs quite frequently, although not usually recognized. Five years later, in 1892, he reported two additional cases, being all that he had seen in five years, so he then modified his first conclusion, and says that primary nephritis in infants is rare and occurs infrequently.

The symptoms he described in this condition are as follows: Continuous fever of an irregular type, generally quite high; dullness and apathy with no focal symptoms of brain disease; marked anemia without emaciation, moderate gastro-intestinal disturbance in the early part, usually vomiting later and a tendency to diarrhea; and later a tendency to bronchitis. These cases all emphasize the fact that in cases of irregular fever in infants for which there is no apparent cause the urine should be examined, and that in case of convulsions in infants the urine should always be examined. In only a few cases was there marked diminution in the amount of urine observable. Dr. Root's case, it seems to me, might possibly belong in this class, the disease of the

kidney not having been caused by infection through the umbilical vessels. Changes in the liver would have been expected and changes in the vessels themselves if the infection had taken place in this way.

DR. ROOT—The temperature in this case was high and during the last two or three days irregular, as Dr. Weaver says, but there was a marked decrease in the flow of urine. No examination of the urine was made, for the reason that we could not secure a sufficient quantity of it.

DR. EDWIN HAMILL—In regard to the last point mentioned by Dr. Root, that of securing a sample of urine from a baby, by placing a flat sponge over the genitals, one may succeed very often in securing urine, without resorting to the use of the catheter.

## A CASE OF NEPHRECTOMY FOR SARCOMA OF THE KIDNEY.

Read before the Chicago Pathological Society, Jan. 14, 1895.

BY D. W. GRAHAM, M.D.

CHICAGO.

This sarcoma was removed from a child 18 months old. There was no history of injury or acute disease. About six months before the operation a tumor was discovered in the child's right side, which gradually enlarged. I saw the case the last week in September and told the parents I would operate if they desired it but did not offer them any encouragement. They declined the operation at that time but returned the middle of November with the request that I operate, even if the child died. I operated with a kind of protest, they knowing all the dangers.

At the time of operation the tumor filled the entire side of the abdomen extending down into the pelvis; it was of enormous size compared with the size of the child. I operated by what is called Langenbeck's method. The incision through the wall is made in the linea semilunaris. The colon is pushed toward the middle line, the peritoneum over the kidney and tumor is cut through and stripped off with the fingers, the tumor being thus enucleated. The pedicle consisting of the usual vessels and the ureter is isolated, the tumor freed from behind and the vessels secured. I will pass this tumor around. The kidney substance is at the upper end, the capsule seems to have been ruptured and the whole mass protruded downward. The mass seems to have come out as a fungus at the pelvis of the kidney, shooting out toward the mid-line of the body, and even surrounding the vena cava. The ureter ran across the tumor. The pedicle was secured in the usual way without great loss of blood. There was a good deal of hemorrhage but it came from the bed of the tumor, there being a good deal of venous oozing which could not be checked readily. For the age and size of the patient a good deal of blood was lost, although the absolute amount was small. The patient lived about four hours and died of shock. A diagnosis of sarcoma of the kidney was made before the operation, and the microscopic examination shows it to be sarcoma of the round-celled variety. The diagnosis was based chiefly on the age of the patient. There is no way of determining beforehand from the clinical symptoms whether a tumor of the kidney is carcinoma or sarcoma, but we know that malignant tumors of the kidney in young children are relatively much more frequently sarcomata rather than carcinomata. Dr. Bishop will describe the sections he has made.

#### MICROSCOPIC EXAMINATION BY DR. D. D. BISHOP.

Pieces were taken from the portion of the specimen which projects above the capsular-like structure and ex-

amed microscopically. In the main we might say the structure is that of a round-celled sarcoma. The cells are rather large, have large nuclei, some are elongated having the appearance of a so-called oat-shape cell which we see in some tumors. The structure is traversed in a gross way by broad bands of fibrous tissue showing well formed connective tissue in their interiors, but as we pass from the interior of these bands toward the tumor itself, the cells become of the same character as the cells in the tumor proper, indicating that perhaps these have developed by fibrillation and condensation of the tumor structure. There are numerous small blood vessels and these show a distinct endothelial lining and a slight amount of connective tissue wall. From the number of blood vessels and the fact that the round cells are arranged rather in groups about these vessels, one might think it likely that the tumor had its origin in the vascular system, and I consider that perhaps this was the fact, because in other portions there are distinct trabeculated areas in which there are rather large spaces and the trabecular walls are lined with endothelium, very much like other angiomata, so we may consider that it is probably an angio-sarcoma. It is interesting to note in all the sections prepared and examined, about twenty-five in number, that in no part of the kidney proper was there evidence of invasion of the sarcoma. The kidney was apparently pushed to one side by the process. The sections from the kidney proper, taken from the capsular-like portion show simply an atrophic condition of the glomeruli, some slight thickening of the walls, compression of the renal tubules and increase in the interstitial tissue. Considering the apparently profound changes and the size of the entire structure the kidney is really very little altered. The renal changes would not be considered very grave if found in a kidney not compressed by a tumor of this sort. In no portion of the structure were there found any of the striated muscle cells which are said to occur often in some congenital sarcomata of the kidney, the so-called myo-sarcoma. So it seems that we have not to deal with that variety of tumor, but a round-celled sarcoma probably developed in the course of the blood vessels.

#### DISCUSSION.

DR. GRAHAM—Many of these cases of sarcoma in young children are accounted congenital. There was a year of life elapsing between the time of birth and the time this tumor was discovered. There was nothing in the history or appearance of things that would lead us to believe that this was not a congenital tumor and I am inclined to think the disease was present at birth.

DR. E. R. LE COUNT—In reference to congenital sarcoma of the kidney of a malignant character, as reported by Dr. Graham, it is very probable that they have their origin in the remains of the Wolffian bodies, while with tumors that appear later in life there is a tendency to consider their origin as having some connection with remnants of the super-numerary adrenal glands.

DR. BISHOP—Dr. Le Count speaks of the Wolffian bodies in connection with these tumors, and I ought to add that in some of the sections are tubular-like structures lined with columnar celled epithelium, suggesting that they are the remnants of the ducts of the Wolffian body, and should not be overlooked, but they were so few in number and had no apparent relation to the tumor so were not considered as having any etiologic significance. The tumor perhaps, but not necessarily, occurred from that structure. I did not mean to say that this tumor was not in my opinion congenital. I simply stated that the striated muscle cells which are often present in such tumors were not present in this; a congenital tumor may be round-celled as well as any other variety.

#### A CASE OF TUBAL PREGNANCY.

Read before the Chicago Pathological Society, Jan. 14, 1895.

BY BERTHA VAN HOUSEN.

CHICAGO.

Mrs. S., aged 22, married three and one-half years had a miscarriage after being married five months. Three months after the miscarriage had an attack of pelvic inflammation, and a pyosalpinx on the right side was diagnosed by Dr. Bayard Holmes, who was caring for the patient at this time. She was confined to bed for six months at this time, and spent six

weeks of the time in Mercy Hospital. She improved while under hospital treatment and was told that she might fully recover if she continued the hot douches after leaving the hospital. Sept. 19, 1894, two years later, the patient came to Dr. Hickey-Carr complaining of nausea and with the history of having missed two monthlies. Examination of the pelvis showed the uterus enlarged and a mass was felt on the right side. Liquid diet was ordered; September 23, the patient was feeling well and took an eight-mile ride on the cable car. September 24, the following day at 3 A.M., she was seized with pain in the pelvis and a neighboring physician was called in. He gave her three doses of codeia  $\frac{1}{2}$  gr. each. At 8 A.M. on same morning Dr. Carr was called and found her still in pain; slight hemorrhage from the uterus but no sign of membranes, pelvic tenderness and the mass on the right more distinctly outlined.

September 24, 25, 26, patient kept in bed on liquid diet without anodynes and efforts made to move the bowels with calomel, castor oil, olive oil, glycerin and water enemas but with no success. Up to and including September 26, the fourth day of the attack, the pulse was 90 to 96, temperature 99 to 99 $\frac{1}{2}$ , and the pain constant. September 27, at 4 A.M., the patient had a third violent attack of pain and by 9 A.M. the pulse had risen to 120, temperature 100. Dr. Carr was obliged to leave the patient to attend court, and did not see her until 2 o'clock in the afternoon. At 1 o'clock she had been seized with pain and went into collapse. When Dr. Carr saw her at 2 P.M. there was dullness in the lower segment of the abdomen and the mass of the right was very indefinite. I saw the patient two hours later in consultation with Dr. Carr. The temperature was then 100, and the radial pulse 160. The patient was blanched and appeared to be sinking rapidly.

Ectopic gestation was suspected and an exploratory operation was decided upon; at 6:30 P.M. the patient was taken to the Chicago Hospital, a distance of four blocks from her home. Dr. F. Byron Robinson saw the patient at 8 P.M., confirmed the diagnosis and at 8:15 with the assistance and consultation of Dr. Robinson, I opened the abdominal cavity, the lower portion of which was packed with loose black clots of blood. These with a quantity of liquid blood were turned out, the appendages on the right side were removed, the cavity freely irrigated, glass drainage tube inserted and wound closed with silkworm gut. At 9 P.M., a few minutes after the operation the pulse was 152, temperature 101.4. From this time the pulse dropped until on the seventh day it did not go above 100. On the fourth day the decidua was expelled entire. Drainage removed on the sixth day and stitches tightened; the wound closed by figure 8 ligature and the patient left the hospital on the fourteenth day. I saw her last week and she asserted she had not been so well as now, since her marriage. Since the operation she has gained in weight, menstruates regularly, and is at all times perfectly free from pain.

The specimen is a very typical one and shows what a violent effort was made to accomplish tubal abortion during the four days before tubal rupture took place.

Such a mishap as this illustrates, fortunately does not occur every day, because nature has practically castrated such women by closing the tubes, or so modifying the secretion that conception can not take

place, but my reading leads me to believe that there are many undiagnosed cases. In fact, it does not seem to be the etiology, the pathology or the treatment that balks us in dealing with this condition, but the blunders in regard to it seem to be confined mainly to the diagnosis. Some of the most typical diagnostic points are well brought out in this history. Before rupture we have history of sterility and severe tubal disease; mass felt on right side; rapid increase in size of mass; symptoms of pregnancy; uterine hemorrhage. After rupture we have sudden pain and collapse; slight elevation of temperature; rapidity of pulse; physical signs of internal hemorrhage. To save a patient after such an accident as tubal rupture seems to me more good luck than good management, but to prevent such an accident from occurring is worthy of the most ambitious efforts.

In this case, salpingotomy should certainly have been performed after the first miscarriage two years ago, as earnestly advised by both Dr. Holmes and Dr. Carr. An infected and diseased tube can never be anything but a source of danger to a woman's health, both on account of its relation to the peritoneum and its inaccessibility to treatment; and for the same reasons I see nothing but salpingotomy that can be relied upon to permanently restore to health a woman with diseased tubes.

If, however, the patient does not give us the opportunity to remove the diseased tube before such a condition as ectopic gestation can occur, should a suspicion of pregnancy in the uterus prevent us from interfering with any mass that could be felt in the pelvis, the conditions that might most easily be mistaken for ectopic gestation are pyo- or hydrosalpinx or an exudation about the tube complicating normal pregnancy. If we had any one of these conditions without pregnancy, an abdominal section would certainly be indicated, and the co-existing pregnancy can not have any but a deleterious influence upon these conditions, by increasing congestion and stopping drainage through the uterus. The effect of any of these conditions upon pregnancy is to constantly threaten aborting before full term is completed, to cause rupture of the tube or prevent natural delivery at the time of confinement, and after the uterus is emptied to increase the danger of sepsis and pelvic peritonitis.

There are so few of even the most distinguished gynecologists who are able to make an accurate diagnosis of any pathologic condition in the pelvis, outside of the uterus, before an incision has been made in the abdominal wall, that the general practitioner in whose hands these cases first fall must feel himself very inadequate to meet the possible emergency. But every practitioner should be able to say whether the uterus was enlarged, and that there was a mass at one side and on finding such a condition should he not advise an exploratory operation at once? A few cases with personal responsibility in ruptured tubes has increased my courage in prompt action and my admiration for the judgment of the man who says conservative surgery means increased mortality.

#### DISCUSSION.

DR. E. F. GAVIN—I have been strongly tempted to suspect abdominal pregnancy of an ectopic nature in a number of cases of acute peritonitis in married women, and I think so-called cases of peritonitis are frequently cases of ectopic gestation.

DR. D. W. GRAHAM—This is a very good report of the case

and is sound teaching. I know the author of the paper is not the author of the last remark; that it is a quotation in regard to conservative surgery. I always feel like fighting when I hear the term used as it is used nowadays. Conservative surgery means that kind of surgery which will save the life or health of the patient. That is my definition of conservative surgery. I know the author of the paper did not use the term in an improper sense, but I want to protest against the phrase being employed every time we are discussing subjects which have to do with removing something from the body. It might be proper to say conservative treatment, or do-nothing treatment, or temporizing treatment, but conservative surgery means conserving the patient's life or health and all the organs compatible with these two conditions. I want to put myself on record as giving that interpretation to conservative surgery.

DR. J. L. McCOLLUM—I feel that too much can not be said in praise of this paper. I have had some experience in operative gynecology, and I must say that I indorse most heartily the ground the Doctor has taken in not hesitating to mutilate, as this method has been termed by a great many writers who cry out against the removal of the tubes. I have had a clinic in gynecology for the last six years and have had an opportunity to watch cases, some of them being under treatment for two years. I would have them discharged as cured but they would come back in a few weeks with the same trouble, which if not as bad was in the way of becoming so shortly. I can not see any reason why we should hesitate to remove the tubes after a reasonable course of treatment is unsuccessful.

DR. F. B. EARLE—I certainly think the author deserves congratulations, both on the paper and the result of her treatment. The diagnosis of ectopic gestation is very difficult before rupture of the sac; in fact, some authors state that it is impossible. However, when we have a history as in this case, of previous disease of the tube with probable occlusion we have one of the principal factors in the etiology. Amenorrhea and a period of sterility so frequently precedes ectopic gestation that the usual symptoms of pregnancy following a condition of that kind should always excite our suspicion. When there is a bloody discharge from the uterus with the negative symptoms of pregnancy, with a tumor presenting at the side of the uterus and pain at the site of the tumor, particularly if that tumor presents a soft boggy feeling, then there is every reason in the world to suspect extra-uterine pregnancy. As to treatment, there can be no doubt as to the indications when the diagnosis is properly made. The ovum at that site is of dangerous omen and the sooner it is gotten rid of the better. The use of electricity to destroy the ovum has many advocates but laparotomy is comparatively safe and inasmuch as it is, and may be called for even after death of the ovum, probably the best method is to resort to it as the primary treatment.

DR. BERTHA VAN HOOSSEN, in closing the discussion, said: I would like to say one word about conservative surgery. I suppose by conservative surgery we mean as simple an operation as possible to save the woman's life; that depends a good deal upon the judgment. I saw an extra-uterine pregnancy operated upon at the Post-Graduate Hospital; the patient had been consulted over by several doctors and each one proposed curetting, until it happened that one consultant thought it might be better to see exactly the condition inside the pelvis. Abdominal section was made and it was found that she had an ectopic gestation on one side and a very large pus tube on the other. I think if curetting had been resorted to it would have been what Dr. Graham would call conservative surgery.

### ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 553.)

#### CHAPTER VIII.

Case of gastritis, fever and jaundice, resulting from exposure and bad diet. John Austin, age 16, laborer, admitted to Charity Hospital Nov. 30, 1876. Says that he had felt unwell for three or four days before admission. Complained

of loss of appetite and diarrhea. Ordered light diet and bismuth mixture.

R. Syrupi morphine . . . . . ʒiij  
Bismuthi subnitrate . . . . . ʒiij

℞: Sig., teaspoonful three times a day or every four hours if necessary.

December 4, temperature of the axilla 101.4. December 5, 101; December 6, eyes and skin decidedly yellow, patient complains of feeling very heavy and depressed. Morning pulse 82, respiration 18, temperature 99.8; P.M., temperature 100.5. December 7, morning, jaundice increasing, decided yellow color of conjunctiva and skin; pulse 72, respiration 18, temperature 99.5; evening, pulse 72, respiration 18, temperature 100.5. December 8, urine high colored and loaded with bile, albumin absent; chlorids abundant; yellow color of conjunctiva and skin. A.M., pulse 74, respiration 18, temperature 99; evening, temperature 100.5. December 9, morning, pulse 80, respiration 18, temperature 95.5; evening, pulse 80, respiration 18, temperature 101.5. December 10, evening, pulse, 76, respiration 18, temperature 102.6. Urine loaded with bile; skin yellow, hot and dry. December 11, morning, pulse 80, respiration 18, temperature 99; evening, temperature 102. December 12, morning, pulse, 80, temperature 100.5; evening, temperature 101.6. December 13, during the past four days quinin has been freely given, the bowels having been previously evacuated by a mercurial purgative. The depth of the color of the skin is now decreasing. Morning, pulse, 84, temperature 99.8; evening, temperature 100.5. Continued to improve and was discharged.

We observe in this case in which jaundice accompanied fever, perhaps of a malarial character, that on January 10, with a temperature of 102.6, the pulse was only 76 beats per minute.

#### PERNICIOUS AND CONGESTIVE MALARIAL FEVER.

The rate of mortality in my surgical practice has varied with the season, the type of the disease and the manner of admission of patients. When from such causes as scarcity of funds, the lighter cases of disease were treated as out-door patients, and only those seriously ill admitted, the rate of mortality among the cases treated in the wards was relatively increased. At the same time the number of out-door patients prescribed daily in the wards was greatly augmented. I have carefully excluded from the statistics recorded in my "Medical and Surgical Memoirs," those relating to out-door patients connected with the Charity Hospital, although during some seasons they have exceeded in numbers those actually treated in the wards. During the twenty-seven months of hospital service, preceding April 1, 1872, the total number of cases admitted into my wards in the Charity Hospital was 1,111; of this number 856, or 77.9 per cent. were discharged, and the deaths amounted to 106, or 9.4 per cent. of the entire number treated; during this period, also, a large number of the cases which terminated fatally were brought in moribund. During the six months ending April 1, 1873, the total admissions numbered 213; of this number 145, or 68 per cent. were discharged. The deaths amounted to 39, or 18.5 per cent. During the first period the deaths amounted to 1 death in 10.4 cases; in the latter period, 1 death in 5.46 cases.

During a period of six months, Oct. 1, 1873 to April 1, 1874 the total admissions numbered 517; of which 436 were discharged and 51 died; the deaths amounting to 1 in 10.13 cases, or 98 per cent. During this period more than one-third or 19 deaths were caused by yellow fever, many of which were brought in moribund, with jaundice and black vomit.

During a period of twelve months, Oct. 1, 1874, to April 1, 1875; Oct. 1, 1875, to April 2, 1876, 765 cases were treated, with 65 deaths, or one death in 11.8 cases, or 8.5 per cent.

I have selected the following cases from the clinical records of my wards, to illustrate the condition in which many of the patients entered, and the effects upon the rate of mortality:

*Case 1.*—Pernicious malarial fever (malarial coma). Unknown man, age about 35, entered Charity Hospital Oct. 17, 1872; died in six hours. Patient brought to the hospital in an insensible condition, from which he could not be aroused; rapid feeble pulse; skin sallow with a decided tinge of yellow; extremities cold, congested and mottled; lips and fingers purple; passes urine and feces freely in bed; head and trunk hot; temperature of axilla 103. Sinapisms and alcoholic stimulants failed to arouse the patient; large doses of quinin administered by enema have no effect.

Post-mortem three hours after death: Blood vessels of brain congested with dark blood; lungs and heart healthy; mucous membrane of stomach and intestines slightly congested; liver slate-colored on the exterior and bronzed within; abundant pigment deposits in portal capillaries; spleen enlarged and softened; splenic mud contained numerous pigment particles; kidneys normal; gall bladder distended with dark green bile; cavities of heart contained fibrinous clots; blood of liver of a dark purple color.

*Case 2.*—Pernicious malarial fever (malarial coma). F. F. Payne, age 32, native of Virginia, entered Charity Hospital Oct. 28, 1872, died October 29, twenty hours after entrance. Has been exposed in swamps of Mississippi River. Admitted in a comatose state. Rapid pulse, congested purplish extremities. When aroused by violent shaking, appears to be in a state of great agitation and gives incoherent answers. Passes excrements in bed. Sinapisms, alcoholic stimulants and quinin produced no permanent effects.

Post-mortem six hours after death: Heart and lungs normal; fibrinous clots in cavity of heart; liver slate-colored on the exterior and bronze within; spleen enlarged and softened; gall-bladder distended with dark green bile. Stomach contained a considerable quantity of greenish-yellow fluid resembling bile; numerous pigment granules were observed in the structures of the liver and spleen.

*Case 10.*—Malarial congestion or pernicious fever. Charles Smith, native of Switzerland, age 60; entered Charity Hospital Oct. 18, 1872, and died October 19. During the summer and fall has been exposed to swamps and marshes. Entered in a state of wild delirium. Rapid feeble pulse; rapid respiration; prostration of muscular and nervous forces; capillaries of extremities congested; head and trunk hot; temperature of axilla 103, which continued up to the time of death. Passed feces and urine in bed. Sinapisms, diffusible stimulants and quinin produced only temporary improvement and the intellect was restored but for a short time. Intense jaundice appeared before death, which occurred in thirty-six hours.

Post-mortem six hours after death: Surface golden colored; heart and lungs normal; liver slate-colored on the exterior and bronze within; much pigment in portal and hepatic capillary network. Gall-bladder distended with dark almost black greenish bile; spleen enlarged and softened; kidneys healthy.

*Case 3.*—Malarial, congestive or pernicious fever. John Kerrin, age 39, native of Denmark. Has suffered for some time with malarial fever, in a low, unhealthy, marshy location. Entered Charity Hospital moribund, pulseless, comatose, Feb. 9, 1873; died in twenty-four hours, Feb. 10, 1873. Diffusible stimulants, sinapisms and sulphate of quinia induced only temporary improvement.

Post-mortem examination: Heart normal; contained fibrinous clots; malarial liver, slate-colored on exterior and bronze within, loaded with black pigment; spleen enlarged, softened and loaded with pigment.

*Case 4.*—J. Duber; malarial fever and dysentery; native of Germany, age 45. Has been exposed in swamps and has been subjected to scant diet and bad water. Entered Char-

ity Hospital Nov. 12, 1872, and died November 19. Entered hospital in a most filthy and miserable condition; comatose; pupils contracted, pulse rapid and thread-like—so rapid and feeble that the number of beats are determined with difficulty. Bowels loose, passes feces and urine in bed. Has been sick for some time. Immense bed sores are forming over scapulars, sacrum and hips. Under the use of large doses of quinin and opium, carbonate of ammonia and alcoholic stimulants the patient rallied and at one time I entertained some feeble hope of his gradual improvement. The change, however, was only temporary, and death appeared to result chiefly from the profuse discharges from the bowels; patient died six days after entering the hospital.

Post-mortem six hours after death: Heart and lungs normal; liver slate-colored on exterior and bronze within with much black pigment; spleen enlarged and contained much pigment; ileum, colon and rectum much congested; numerous ulcerations in mucous membrane of colon and rectum. In the chronic dysentery of the Mississippi Valley and of the Southern States generally, I have found by post-mortem examination that ulcerations of the large bowels are almost always present.

*Case 5.*—Malarial congestive fever, with hemorrhage from the bowels. John Kelly, age 42, native of Ireland. Entered November 11 and died November 13. Cause of disease, exposure on banks of Mississippi and bad diet. Entered in a delirious feeble state with rapid feeble pulse; distended abdomen; enlarged liver and spleen; anemic, sallow, greenish-yellow malarial hue. Passes foul stinking feces in bed. On the night of the 12th the patient had a prolonged (congestive) chill, which was attended by a profuse discharge of fetid bloody matters in his bed. Quinin, opium, stimulants and sinapisms produced only temporary effects, and prolonged life only a few hours.

*Case 6.*—Malarial congestive fever and dysentery; profuse hemorrhage from bowels. F. Harrington, age 33, native of Ireland. Entered Charity Hospital Jan. 11, 1873, died January 21. Has been exposed to the prolonged action of malaria, cold, and wet, and bad diet in swamps along the Jackson R'y. Entered with feeble rapid pulse; sallow and anemic, jaundiced hue; liver and spleen enlarged; suffers with quotidian intermittent fever and painful chronic dysentery; discharges from bowels painful, frequent and loose. Under the free and continuous use of subnitrate of bismuth, opium and quinin, with milk and rice diet, there was marked improvement. On the night of January 18, patient had a prolonged and severe congestive chill attended with profuse hemorrhage from the bowels, which was followed by collapse and death.

Post-mortem six hours after death: Heart and lungs normal; liver slate-colored on exterior and bronze within, with much pigment matter; spleen enlarged; mucous membrane of large intestine ulcerated.

*Case 7.*—Pernicious fever and dysentery terminating fatally with profuse hemorrhage from bowels. Timothy Harrington, age 32, laborer; admitted to Charity Hospital Jan. 11, 1873. Patient states that he was taken two weeks ago with violent pain in the lower bowel, with frequent desire to go to stool, and great tormina and tenesmus. Bowels moved six or eight times in twenty-four hours. January 13, pulse 100, of good force and volume. Complexion anemic and greenish-yellow, spleen and liver enlarged and has been exposed to the action of malaria. Temperature 102 degrees. Applied blister on right iliac region for relief of pain. Administered 5 grains of quinin and 10 drops of the tincture of opium every three hours, until four doses were taken. Fever not affected by quinin perceptibly; patient restless and complains of pain in bowels. January 15, pulse 108, very feeble; patient feeble and weak. During the night of the 15th had a protracted and severe chill of the type ordinarily called congestive; extremities purple; pulse a mere thread. January 16, patient in a state similar to the cold stage of congestive fever; cold clammy sweat on the surface; complete prostration; pulse rapid and feeble; turpentine stupes and sinapisms were applied and quinin and alcoholic stimulants administered, both by the mouth and by the rectum. These measures brought on reaction and the patient appeared to be improving. The temperature of the axilla, however, during this period of depression and

coldness of the extremities was above the normal standard, as will be seen by the following record: January 13, temperature 102, pulse 100, respiration 18. January 14, temperature 100, pulse 99, respiration 17. January 15, A.M., temperature 101, pulse 86, respiration 19. January 16, temperature 101.5, pulse 108, respiration 18. January 17, temperature 102, pulse 88, respiration 23. January 18, patient vomiting large quantities of biliary matter and utterly unable to retain anything on his stomach; A.M., temperature 101, pulse 84, respiration 18. January 19, during the nights of the 18th and 19th the patient was again affected with a prolonged congestive chill, attended with profuse hemorrhage from his bowels. His bed was literally flooded by the hemorrhage from the bowels. Pulse 128, respiration 18, temperature of axilla 100. I examined the urine with great care and interest in the case, as it bore striking resemblance to some cases of malarial hematuria. The urine contained no blood corpuscles and no albumin, but abundant urea, urates and uric acid; was of a bright straw color, strong acid reaction; specific gravity 1025. January 20, temperature 100.5, pulse 120, respiration 20. Died January 20.

Post-mortem. Twelve hours after death: Heart and lungs normal; liver enlarged, slate-colored on exterior, bronze within, loaded with pigment particles; spleen enlarged and softened; mucous membrane of intestine congested; large intestine ulcerated.

*Case 8.*—Intermittent fever arrested by full doses of the sulphate of quinia. James Davis, age 25, native of England, has been exposed to the action of malaria in the swamps of the Red River. Entered Charity Hospital January 19, discharged Jan. 27, 1873. Upon entrance complained of pain in right side. Had severe chill during night of 21st. Bowels opened with 10 grains of calomel, combined with 5 grains of quinin and followed with 5 grains of quinin every two hours, until 20 grains were taken. Under the action of the quinin there was a rapid subsidence of the temperature. The quinin was continued; about 10 grains being administered daily for several days; no return of chill and fever. This patient had had chill and fever every alternate day up to entrance in hospital. The following observations illustrate the rapid fall of temperature under the action of quinin: January 21, 8 A.M., chill just passing off, temperature of axilla 106.3; quinin freely administered. At 8 P.M., temperature 102.3. On 22d, at 8 A.M., temperature 99.3; 8 P.M., temperature 99. On 23d, 8 A.M., 99.4; 8 P.M., 100. On 24th, 8 A.M., 98.5; 8 P.M., 98.4. On 25th, 8 A.M., 98.4; 8 P.M., 99.2. On 26th, 8 A.M., 99.4.

*Case 9.*—Congestive fever; loss of muscular power, general paralysis, loss of memory. Recovery. Peter O'Brian, age 41, native of Ireland, laborer. Enjoyed good health up to November, 1872, when he left St. Louis, Mo., where he had been employed as a ditcher, with the intention of settling in New Orleans. On his passage down the Mississippi River to New Orleans he was robbed and left destitute. After arriving in this city he was for nearly a week without shelter or sufficient food, and slept at night on the levee without covering of any kind, during cold and inclement weather. This exposure and want of food so reduced the strength of the patient that he was compelled to apply for lodging at the police station, where he was "very ill with chills and fever." From the police station he was transferred to the workhouse, in which place "becoming much worse," he was sent to the Charity Hospital. He was brought in January 12, 1873, in an insensible comatose state, with loss of speech and power of motion. Lay insensible in the bed, passing his urine and feces involuntarily. Could not be aroused. At times the patient appeared to suffer with true malarial chills, attended with shivering, depression of the temperature of the extremities, elevation of that of the trunk and congestion of the peripheral capillaries, and followed by general diffusion of heat and high temperature.

Regarding the chills, fever and coma of malarial origin and aggravated by exposure and starvation, I placed the patient upon a solution of quinin:

R. Quinæ sulph. . . . . gr. xxx.  
Acidi citrici . . . . . 5ss.  
Tinct. cinchonæ comp. . . . . f ʒviij.

Mix: Tablespoonful in wine glassful of water, every four hours; and ordered beef tea and milk punch, every two hours.

Under this treatment, the improvement was slow but gradual, and on January 7, he was able to give a

few coherent answers. The brain, however, was in such an enfeebled condition that he was able to give his name and answer a few questions, when his mind would wander and he would relapse into an unconscious condition. The quinin with tincture of cinchona and quassia, and the nutritious diet was continued, and on January 13, the thirty-second part of a grain of strychnia, in solution with the citrate of quinin and iron was administered three times a day.

R. Strychnia sulph. . . . . grs. ij.  
Acidi citrici. . . . . ʒij.  
Quinæ et ferri citrati. . . . . ʒiij.  
Aquæ destillatæ. . . . . f ʒviij.

Mix: Sig., teaspoonful three times a day.

This patient was carefully observed by the students of the ward, and was also at regular intervals brought before the entire class in the amphitheater, in order that the gradual improvement of the mental and muscular power might be noted. The patient slowly progressed to complete recovery and was discharged at the end of sixty days.

#### CHRONIC MALARIAL POISONING.

*Case 1.*—Great anemia; fatal results. D. Hoffman, age 28, native of Germany, came to this country two years ago. After remaining in New Orleans one month, went to Franklin Parish to work on a plantation. Was taken sick with chills and fever three weeks before entrance into the hospital, and during this time had little or no medical attendance and had but indifferent supplies of food: Entered Charity Hospital, Oct. 28, 1873. Pale, anemic; hands bloodless and when held up to the light resembled semi-transparent light yellow and greenish wax. Countenance pale, yellowish green, swollen and bloated. Lips and tongue pale like the face; tongue pale, large, flabby, with the edges indented by the teeth. Action of heart loud, rapid and irritable, with loud anemic murmur. The anemia in this case was as intense as in the most pronounced cases of chronic malarial poisoning in the Mississippi valley. Belly and lower extremities anasarca. October 29, 8 p.m., pulse 110, respiration 20, temperature 103.5. October 30, 8 a.m., pulse 104, respiration 20, temperature 101.5. October 31, 8 a.m., pulse 106, respiration 24, temperature 101.5; 8 p.m., pulse 106, respiration 24, temperature 101. November 1, pulse 100, respiration 20, temperature 101.5; 8 p.m., pulse 108, respiration 25, temperature 101.5. November 2, pulse 108, respiration 18, temperature 101.5; 8 p.m., pulse 100, respiration 20, temperature 100. November 3, pulse 116, respiration 28, temperature 101.6; 8 p.m., pulse 112, respiration 32, temperature 100. November 4, pulse 104, respiration 22, temperature 101. The patient complained of pain in the epigastrium and region of heart together with great dyspnea. The difficulty of breathing appears to be clearly due to edema of the lungs, induced by the watery condition of the blood, and is similar to the universal anasarca with which all parts of the patient appeared to be afflicted. The distress in breathing and the pain in the heart increased during the night, and was attended with great thirst. The patient died at 8 a.m., November 5. Death apparently due to edema of the lungs. The preceding changes wrought in the blood and textures by the malarial poison were the chief causes of death.

*Autopsy:* Two and one-half hours after death. Body warm and limber in *rigor mortis*. Exterior, full bloated anasarca appearance; cellular tissue infiltrated with yellow serum, color greenish yellow, resembles a Chinaman. Chest, lungs bloodless, pale, anemic; edematous. Heart enlarged, with dilatation of right auricle and ventricle; color of heart natural; when the textures of the heart were carefully examined under the microscope with magnifying powers of various degrees, the transverse striæ were found to be distinct and there were deposits of granular and pigmentary matter within and around the fibers of the heart as in yellow fever. Cavities of the heart distended with dark fluid blood. Specific gravity of blood 1023.3; specific gravity of serum 1017; solid matters in 1000 parts of blood 77.71; in 1000 parts of

serum, 60.94; 1000 parts of blood in the patient contained not more than 17 parts of red blood corpuscles in 68 moist blood corpuscles, while in healthy blood the moist corpuscles may reach 600 parts; the liquor sanguinis 400 parts. In the present case the liquor sanguinis was 932 parts in 1,000. Under the microscope, the colorless corpuscles were found to be greatly increased, relatively to the colored corpuscles. Abdominal cavity: Liver slate on the exterior, and bronze within. Under the microscope the liver cells were found to be loaded with dark pigment particles, which were also deposited in large numbers within and around the portal capillaries. When sections of the liver were made with Valentine's double-bladed knife and examined under the microscope, numberless dark pigmentary masses were seen both in the portal and hepatic systems of capillaries. Liver firm, evidently undergoing a hardness or cirrhotic change which appeared to be due to the action of malaria. Gall bladder distended with dark green bile, about two fluid ounces. Bile thick and ropy. Specific gravity of bile 1022. Solid matter of bile 1000 parts, 82.19. The bile was actually of very nearly the same specific gravity as the blood, and contained more solid matter. Spleen enlarged and loaded with dark pigment particles. Kidneys firm and normal.

In the preceding case quinin, nutritious diet and alcoholic stimulants were used but without avail.

*Case 2.*—Chronic malarial poisoning; intense anemia; jaundice; high temperature; anasarca; fatal issue. P. Eghart, age 25, laborer, native of Germany. Has been in Louisiana eight months. Has been living in a low swampy region. Has had chills and fever, with little or no medication and with scant supplies of coarse food. Entered the Charity Hospital on the evening of Nov. 22, 1873. November 23, pale, sallow and greenish-yellow complexion, bloated, swollen features; extremities edematous; scrotum swollen; feeble prostrated condition; great prostration of nervous and muscular forces; rapid feeble pulse; loss of appetite; anemia complete; lips and tongue pale; when hands are held up to the light they present a wax-like almost semi-transparent appearance; tongue pale, flabby and indented at the sides; urine high colored but free from albumin and casts.

Before coming to this country this patient followed the trade of architect and enjoyed good health. His present deplorable condition is clearly referable to the action of the malaria of the swamps.

November 24, 8 a.m., pulse 112, respiration 21, temperature of axilla 105 degrees, 8 p.m., temperature 104.8. November 25, continues in the same condition only apparently more feeble; can take but little nourishment. Quinin administered freely; 8 a.m., pulse 116, temperature of axilla 103; 8 p.m., temperature of axilla 104 degrees. November 26, delirium, great prostration, jaundice quite intense. Pulse rapid and feeble; skin hot and dry; tongue dry and pointed. Great thirst, nausea and vomiting. Can retain no nourishment on stomach. It has been difficult to introduce nourishment by the rectum on account of the irritable condition of the bowels. Urine high colored but free from albumin and blood. Chlorids present but diminished in amount. 8 a.m., temperature 102; 8 p.m., temperature 103. Died at 6 a.m., November 27.

*Autopsy* three hours after death: Body warm, limbs flaccid. Exterior, color of surface yellowish-green; lower extremities edematous; belly full. Thorax: Pericardium contained about two fluid ounces of golden yellow serum. Heart, of the normal deep color of this organ in health; perhaps it would be more accurate to describe the color as of a deep purplish red; muscular structures of the heart firm. Under the microscope the muscular fibrillæ presented a normal appearance, with distinct transverse striæ; and there was also a complete absence of the yellow granular molecular matter and oil

globules characteristic of yellow fever. Surely such cases as these now recorded, when the malarial poison has exerted its unobstructed action in healthy Europeans, must yield unexceptionable results in settling the character of the changes induced in the chemistry and minute anatomy of the organs by the malarial poison. Heart normal in size.

Microscopic and chemic examination of the blood from the cavities of the heart and from the vena cava:

Specific gravity of blood . . . . .	1021
Specific gravity of serum . . . . .	1015
Solid residue in 1,000 parts of blood . . .	73.00
Solid residue in 1,000 parts of serum . . .	58.00

The blood of this patient contained less than sixteen parts of dried colored blood corpuscles in 100 parts of blood. The true composition of the blood as compared with that of normal blood would be 64 parts of moist colored corpuscles and 936.00 parts of liquor sanguinis, against 600 parts of moist corpuscles and 400 parts of liquor sanguinis in healthy blood.

The blood from the cavities of the heart contained a large number of dark irregular masses of hematin of various sizes, from 1-2000 to 1-500 of an inch in diameter. These dark pigment masses were similar in all respects to those found in the textures of the liver and spleen. The blood also contained oil globules which accumulated upon the surface during the coagulation. Fibrin diminished, coagulum large and soft. Heart normal in size and structure. Lungs healthy with the exception of hypostatic congestion of dependent portions. Abdominal cavity: Stomach distended with gas, and pale; anemic in appearance. Contained a quantity of liquid deeply tinged by bile.

Liver: Enlarged and somewhat hardened; deep slate color on the exterior and bronze within. Liver cells contained but few oil globules, but on the contrary many dark pigment particles. Sections with Valentine's double-bladed knife, revealed under the microscope numerous irregular masses of dark pigment, deposited both in the portal and hepatic capillary network. The pigment was deposited on the walls of the veins and secreting structures as well as in the cellular interspaces. Gall bladder flaccid and contained about 50 grams of thin mucoid yellow bile, loaded with the desquamated cells of the mucous membrane of the gall bladder. Spleen, enlarged and softened, with numerous dark pigmentary particles. Kidneys, normal, with the exception of two slate-colored spots, about half an inch in diameter on each kidney. Discoloration due to deposits of black pigment particles.

Remittent fever. B. Casavan, age 27, laborer, native of France. Entered Charity Hospital Nov. 6, 1875. Patient entered with delirium and jaundice, and upon a superficial view resembled a case of yellow fever. November 7, 8 A.M., pulse 115, respiration 30, temperature of axilla 104.5. Tongue very red about the edges, furred in the center and cracked. Hemorrhage from both tongue and gums. Gums red and swollen. Upon inquiry I found that this patient had been working on the lower coast and had suffered with paroxysmal fever for about twenty days before entering the hospital. At 8 A.M., pulse 137, respiration 24, temperature 105.2. Notwithstanding the increase in the pulse, which differs from that of yellow fever, the appearance of this patient resembles closely that of yellow fever. A careful record of the pulse, respiration and temperature was kept and the urine examined daily; the case although presenting in its general features the appearance of yellow fever, was clearly not this disease, as shown by the following facts: 1, the temperature exhibited marked periodic depression and elevation as in

paroxysmal fever; 2, the urine was wholly free from albumin and casts and manifested periodic changes as in malarial fever depositing during the remissions heavy deposits of urates and triple phosphates. The fever was finally and completely arrested by sulphate of quinia and the patient discharged December 1. The following is the record of the temperature, pulse and respiration:

Date.	Pulse.		Resp.		Temp.	
	M.	E.	M.	E.	M.	E.
1873						
Nov. 7	115	137	30	34	104.5°	105.2°
8	117	133	31	37	102	104
9	96	102	27	36	102	103
10	96	90	28	30	101.5	102
11	96	90	17	26	100	101.5

#### PATHOLOGIC ANATOMY OF THE HEART IN YELLOW FEVER.

It appears to be well established that in malarial fever the pulse and temperature are subject to great and sudden variations, and that quinin has the effect of diminishing the frequency of the pulse, so that in many grave cases of malarial fever, the pulse especially when the patient has been treated with quinin falls to a very slow beat as in yellow fever. This will be illustrated by the following statement of cases, which I have selected, as it were at random without any reference to a special selection:

Remittent fever. Henry Bouteau. Entered Charity Hospital Sept. 29, 1873; native of Germany. Had been working in Red River rapids, and had suffered with intermittent fever for two weeks before entering hospital. Pale, anemic, had had chills every day. October 18 had a severe paroxysm of fever which is here recorded. Discharged cured October 27. Urine light color and without albumin. A.M., pulse 112, 80, 68; respiration 50, 47, 30; temperature 105.4, 100.5, 98. P.M., pulse 105, 85; respiration 47, 45; temperature 103.2, 101.

Remittent fever. I. Madden, age 22, native of Germany. Entered Charity Hospital October 1, with severe hemorrhage and high fever. Arrested temporarily by quinin. October 8, day of first observation recorded; headache, bowels constipated, tongue dry, furred, brown and rough like sandpaper. Quinin arrested the paroxysm and relieved the pulse and temperature. Urine contained bile but no albumin. A.M., pulse 94, 65, 67, 80; respiration 31, 22, 22, 20; temperature 100, 96.3, 98.7, 96.6. P.M., pulse 96, 75, 90, 64, 70; respiration 38, 28, 27, 23, 22; temperature 101, 103.6, 103.2, 98, 97.5.

Chronic malarial poisoning. L. Meyer. Entered Charity Hospital Oct. 3, 1873. Had been sick with chills and fever for two months before entrance into hospital. Entered in a state resembling congestive chill; delirious; rapid, feeble pulse. Disease arrested by quinin. Observations began October 8 and 9. Patient ordered quinin. A.M., pulse, 55, 50, 54; respiration 15, 15, 12; temperature 97.5, 97.8; 98.3. P.M., pulse 60, 61, 54, 53; respiration 18, 12, 15, 14; temperature 97.4, 98, 98.5, 99.

J. Kousben, age 30, native of Germany. Has resided in New Orleans three years. Occupation, brewer. Admitted Oct. 6, 1873. Sick for six days before entering hospital. Observations began on October 8. Entered with high fever, arrested by quinin. Tongue still furred; urine high colored but free from albumin. P.M., pulse 68, 72, 80, 78; respiration 18, 16, 15, 20; temperature 96.8, 98.5, 98.9, 99; pulse 76, 72, 72, 82, 74; respiration 18, 18, 16, 24, 20; temperature 97.4, 97.8, 99.4, 100.4, 94.

Remittent fever. R. Brethan, age 50, native of Germany, laborer. Resided in New Orleans three years. Had been sick for eight days with remittent fever. Entered with high fever; dry, rough, brown tongue. Urine red but free from albumin. Disease arrested by quinin, 20 grains every day. Recovered. A.M., pulse 74, 84, 66, 60, 68; respiration 18, 18, 17, 17; temperature 99.2, 100.2, 99.2, 99.6, 99.4; P.M., 76, 74, 68, 66,

70; respiration 20, 20, 22, 18, 17; temperature 98.72, 100.4, 100.2, 100, 99.8, 99.7.

Remittent fever. Convalescence. G. Peifer, age 33, laborer, native of Germany. Sick fourteen days before entering hospital. Resided in New Orleans fifteen years. Admitted Oct. 7, 1873. Had fever and dry furred tongue at time of admission, with great prostration; urine free from albumin. Observations began on next day, October 8. Quinin administered and with good effect. A.M., pulse 79, 74, 72, 68; respiration 15, 18, 16, 15; temperature 97, 98, 99.6, 98.8. P.M., pulse 96, 74, 72, 70, 66; respiration 18, 14, 15, 15, 14; temperature 98.3, 98.2, 98.5, 98.2, 99.1.

George Wilson, occupation wood chopper, age 20, native of New Orleans; attacked with dizziness, pain in head and fever Sept. 24, 1873. Entered Charity Hospital October 1. Complexion yellow, gums yellow, constipated, pain in epigastrium, brown furred tongue. Quinin arrested the fever. Observations began October 8, A.M., pulse 72, 71, 62; respiration 22, 23, 20; temperature 99.5, 97.5, 98.6. P.M., pulse 78, 67, 61, 66; respiration 22, 22, 22, 22; temperature 98.2, 98, 97.8, 98.5.

Remittent fever. F. McKenna, age 35, native of England, laborer. Attacked five days before entering hospital. Has resided in America one year; in New Orleans six weeks. Has been working on dredge boat. Admitted to Charity Hospital Oct. 13, 1873. On admission, high fever, brown, dry tongue. Observations began October 16, while patient was under the influence of quinin and he perspired freely. Quinin 15 to 20 grains daily. No albumin in urine. Discharged October 20. A.M., pulse 74, 62, 60, 57, 54; respiration 22, 14, 16, 18, 16; temperature 103.8, 99.4, 99.3, 97.25, 98. P.M., pulse 89, 60, 61, 56; respiration 22, 16, 18, 20; temperature 103.2, 90, 95.5, 99.

James Topliff, native of New York, age 30, clerk. Admitted Oct. 10, 1873. Resided in city one week. Disease remittent fever. Taken sick October 9. Urine light colored, no albumin. October 11, high fever, vomited green bile. Bowels opened with mercurials and fever treated with quinin, 15 to 30 grains daily. Observations began October 11. Discharged cured October 24. A.M., pulse 84, 72, 64, 88, 82, 60; respiration 14, 16, 16, 18, 20, 18; temperature 101.5, 100.7, 101, 103.1, 102, 98.4. P.M., pulse 80, 72, 72, 94, 78, 60; respiration 18, 17, 24, 14, 20; temperature 101.8, 101, 101.4, 105.7, 99, 98.4.

Remittent fever. John Gilmore, age 24, admitted to Charity Hospital Sept. 30, 1873. Had been sick two weeks before admission to hospital. Native of Ireland; has resided in Louisiana three years. Urine free from albumin. October 13 had a paroxysm of fever, which was arrested by quinin. Discharged October 27. A.M., pulse 100; respiration 22; temperature 104.8. P.M., pulse 96; respiration 22; temperature 103.8.

Remittent fever. George Letz, age 40, German; resided in New Orleans five years. Entered Charity Hospital September 29. Sick four or five days before entering hospital. October 3 had a paroxysm of fever. Quinin arrested the fever and reduced the pulse. A.M., pulse 82; respiration 22; temperature 102.4. P.M., pulse 90; respiration 26; temperature 104.5.

Remittent fever. J. Dudley, age 24, native of New Orleans. Has had malarial fever for three consecutive seasons. Has been working on a plantation on the Bayou Têche. Entered October 24. Observations began October 31. Very obstinate case. Quinin finally arrested the disease. No albumin in urine. Improved on quinin and iron. A.M., pulse 86, 76, 78, 98, 92, 92, 82, 70, 80, 76, 84, 84, 83; respiration 20, 20, 18, 25, 20, 16, 20, 16, 20, 20, 16, 22, 23; temperature 102.3, 99, 100.6, 101.5, 102.7, 102, 102.7, 100.5, 101, 102.5, 101, 102. P.M., pulse 84, 92, 78, 98, 98, 86, 82, 84, 92, 88, 87, 86; respiration 20, 20, 18, 25, 20, 24, 20, 16, 16, 20, 19, 20; temperature 101.4, 101, 100.8, 101.5, 102.5, 102, 102.7, 101, 102.5, 100, 102.

Chas Schmidt, age 42, native of Austria. Has had yellow fever. Entered Charity Hospital and observations begun Oct. 23, 1873. No albumin in urine; delirious; tongue red at tip and edges, dark brown in the center. Pain in head, bones and epigastrium. Discharged October 31. A.M., pulse 120, 78, 88, 80, 64, 66, 58, 68; respiration 46, 24, 30, 27, 22, 20, 18, 28; temperature 105, 99.2, 104, 100, 98.5, 97, 98.4, 98. P.M., pulse 110, 98, 84, 66, 64, 52, 62; respiration 30, 35, 28, 25, 22, 24, 20; temperature 103.9, 103.5, 103.5, 99.1, 97.5, 97.8, 97, 99.1.

Chronic malarial poison. Remittent fever. Charles Tinbers, age 21, native of France. Has been in New Orleans six weeks; sick two months before entering. October 2, had chill followed by fever. Severe headache, restless, pale and anemic. Urine red and free from albumin. Treated with full doses of quinin. Disease arrested November 5. Bile in urine; no albumin; specific gravity 1025. A.M., pulse 90, 88, 74, 72;

respiration 22, 25, 18, 16; temperature 103.8, 100, 101, 101.2, 98, 98.2. P.M., pulse 108, 92, 90, 80; respiration 44, 26, 24, 19; temperature 100.5, 98.4, 100.8, 98.

Intermittent fever. John Gilmore, native of Ireland. Entered Oct. 30, 1893. Had chills and fever five days before entering hospital. October 31, when record of pulse and temperature was begun, had a chill at 100 degrees, followed by high fever, and at 7 P.M. the temperature was 106 degrees, pulse 108, respiration 24. Sulphate of quinia was freely administered and the fever ceased November 13 and did not return. This was a clear uncomplicated case of intermittent fever. A.M., pulse 72, 73, 74, 80; respiration 18, 20, 22, 18; temperature 99.5, 100.4, 100.8, 98.8. P.M., pulse 104, 79, 72, 74; respiration 24, 23, 18, 18; temperature 106, 101, 100.6, 98.

Intermittent fever. Michael Dolan. Sick one week before entering hospital, Oct. 23, 1873. Observations begun October 26; general appearance anemic, pain in epigastrium. Had fever on 23, when entering. Quinin freely administered, arrested the fever. A.M., pulse 60, 54, 48, 52, 50, 60, 54, 58; respiration 28, 24, 26, 20, 24, 19, 18, 19; temperature 98.5, 98, 98.5, 98, 98.8, 98.6, 97, 98, 98. P.M., pulse 52, 52, 43, 48, 52, 56, 55, 52; respiration 24, 22, 30, 20, 24, 24, 24, 18; temperature 96, 98, 98.2, 99, 99.5, 99.2, 100, 98.5.

In many severe and fatal cases of yellow fever the respiration is often greatly accelerated, as in the following case which entered Charity Hospital Oct. 10, 1873. Had been sick for five days. At 6 P.M., shortly after entrance, pulse 84, respiration 48, temperature 102.4. Patient delirious, restless and vomiting black vomit; suppression of urine. Died next morning at 8 o'clock.

(To be continued.)

## PERITONEAL SUPPORTS—(LIGAMENTUM PERITONEI.)

BY BYRON ROBINSON, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE SCHOOL, CHICAGO.

(Continued from page 546.)

It is likely that the meshwork of perforations in the great omentum is due to the arrangement of the blood vessel and an atrophy of the intervening space. In the horse the mesentery becomes thin and occasionally, Dr. Baker informs me, that a strangulated loop of intestine is found protruding through the perforated mesentery. In the dog I have found very thin, transparent areas, but never a perforation of the mesentery.

FIG. 7.—Shows the continuation of the different portions of the mesentery, (after Perignon).

A noticeable feature in the structure of the mesentery in general is the accumulation of fat. The fat formation is more apparent in animals than in man. Typical samples may be observed in the sheep or especially in the dog. The fat accumulates along the blood vessels and is in many animals quite ornamentally arranged in the great omentum. The color of the fat is white or yellow. In young fattening animals it is apt to be white, but senility increases the yellow color. In very early embryos no fat can be seen, even with a strong lens. Small accumulations

of fat may be observed in embryos in the last of the fourth month and afterward in limited quantities. It, however, does not readily accumulate until the last two months of pregnancy, when the infant, in general, acquires fat. The fat lobules are contained in the fibrous meshwork of the membrana mesenterii propria. The fat mainly accumulates at the base of the mesentery. In some cadavers the great omentum will reach, in places, three-fourths of an inch thick and covers the whole visceral organs from view like a thick quilt. In some cases on which I have performed laparotomy there was a mighty omentum which buried all viscera beneath it—and this is a great protector against general infective invasion of the peritoneum. Fat exists in the mesenteries in accordance with the conditions of the body elsewhere. Mesenteric fat appears and disappears with fat in the other portions of the body.

FIG. 8—Represents the three distinct divisions of the digestive tube each supplied by a distinct artery. S, stomach supplied by the gastric artery, G, A; G, L, the great intestinal loop supplied by the superior mesenteric artery, and I, M, A, the inferior mesenteric artery supplies the left half of the transverse colon and the descending colon; L, shows the growing liver; Sp, the spleen, and P, the pancreas; A, the aorta; C, cecum; M, Meckel's diverticulum; U, umbilicus; H, L, round ligament; L, O, lesser omentum.

A good view of the membrana mesenterii propria may be obtained by selecting a spare cadaver. After opening the abdomen, carefully tear off the epithelial layer from both sides of the mesentery. By a little patience one can easily peel off a thin layer of peritoneum from each side of the mesentery, whence will be left the mesenterii membrana propria, the middle layer of the mesentery, with all its essential structures—vessels, nerves, connective tissue and lymphatic glands. This middle layer may also be separated in two layers—one each side of the vessels and nerves. The layers seem to me not only to vary, from the amount of contained fat, but also that in a very spare individual much of the connective tissue is absorbed, and that with the regaining of the fat much more connective tissue reappears. The two layers of the membrana mesenterii propria decrease in size from the base of the mesentery up to the point of

divergence to embrace the bowel. At its base it consists of a dense thick mass of connective tissue bundles inclosing the vessels and nerves. Its thickness and rigidity supports the viscera and maintains definite anatomic and physiologic relations. It must exercise considerable influence in the caliber of blood vessels which pass through its meshes and fibrous layers.

The lymph glands are not visible in the mesentery of very young embryos. Some state that the glands first appear in the fifth month of fetal life. They appear, according to Toldt, in the middle of the fifth month. The glands lie about the middle of the mesentery and do not seem to produce manifest changes. They lie in a series in the mesentery. In adult man there are some one hundred and fifty. In the lower animals the glands do not assume the scattered and diffuse condition of man but accumulate into a few larger ones. In some, there may be one very large gland, and none, or scarcely any visible small ones. These mesenteric glands are beautifully shown in a six months infant, dead from some wasting disease.

FIG. 9—Represents the mesentery suspending an advanced digestive tube. S, stomach; D, duodenum; S, M, A, superior mesenteric artery; I, L, intestinal loop; M, G, posterior mesogaster; C, A, celia axis; G, A, gastric artery; M, D, mesoduodenum; M, C, mesentery; I, M, A, inferior mesenteric artery; A, aorta. The mesentery, 3 divisions, with 3 arteria and divisions of the digestive tube, appear in this figure.

The two endothelial layers which cover the membrana mesenterii propria are very thin. One can separate them from the middle layer by careful dissection. These two thin serous layers consist of fibrous and elastic connective tissue covered by pavement or flat epithelium. The fibrous, elastic connective tissue which lies between the single epithelial layers and the membrana mesenterii propria does not have a specially definite arrangement for its fiber bundles. It connects the epithelial layer to the subserous beds of tissue. Toldt gives a simple layer of endothelial cells; immediately under the epithelium is a thin layer of fibrous connective tissue, mixed with fine elastic fibers; and an extremely delicate and loose subserous tissue which connects it to the membrana mesenterii propria. It may be observed that the

loose subserous tissue gives the shifting and sliding property to the serous layer. The peritoneum can glide on its soft elastic bed. Fat is rare in this serous layer.

FIG. 10—Shows the mesentery with its three arteries and three parts of the digestive tract. The great intestinal loop, S, I, has rotated from left to right and the acquired mesenteries are beginning to arrive; the cecum, C, is on its travels to the right iliac fossa; the vasa intestinalia, V, I, T, now diverge to the left; Du, duodenum; A, aorta; G, A, gastric artery; Mes, mesentery; S, M, A, superior mesenteric artery; I, M, A, inferior mesenteric artery.

The mesentery is generally viewed as a double fold or duplication of peritoneum, and that as such it originated. But some authors think that the mesentery arose as an independent structure from the cells of the mesoderm adjacent to the vertebral column. The author who supports this view with the most originality, so far as we are aware, is Professor Toldt of Vienna. Toldt observes that nowhere in the development of the mesentery can one discover a process which can be indicated as a fold or duplicature. Nor can the formation of the primitive mesentery be looked upon as a passive extension of a peritoneal fold. Toldt says: "*Das Wachstum der Gekröse ist Viel mehr ein ganz actives; es schnert parallel mit dem Wachstum des Darmes fort und beide bedinger sich gegenseitig.*" (The growth of the mesentery is moreover an active process; it progresses parallel with the growth of the intestine and each limits the other). The advocates of the theory that the mesentery is an independent growth, put forth the idea that not only the development but also the structure of the mesentery favors its correctness. The structure of the mesentery consists of blood vessels, nerves and lymphatics, and these being the fundamental structure of the mesentery it speaks against the view of peritoneal folds or duplicatures. The claim is that no simple fold or peritoneum would always contain such fundamental structures. The distinct difference between simple peritoneal folds and such structures as mesenteries consists in their contents. The constant presence of distinct vital elements is in favor of an independent origin of the mesentery from the mesoderm. The structures of the mesentery may be designated as subserous tissue. Another point which may be of aid in supporting the independent origin of the mesentery is that a part of the intestine loses its free

mobility after early fetal development, as the duodenum, colon ascendens et descendens. The membrana mesenterii propria is the union of the vessels, nerves and lymphatics in a subperitoneal tissue.

Again, the theory of the independent origin of the mesentery may find support in the view that the great omentum has a similar histologic structure as the only primitive mesentery. The great omentum consists of a connective tissue layer covered on both sides with flat epithelial cells, exactly as the primitive mesentery was composed. The fibrous elements are relatively scarce the further one goes from the original mesenteric insertion line. However, the blood vessels are surrounded by fibrous bundles of connective tissue in the great omentum, but the quantity of fibrous bundles is more limited in distribution. It may be asserted that the connective tissue of the great omentum resembles and is analogous to the membrana mesenterii propria. So far as I am able to observe, this is a fact, but it is exceedingly thin, as Dr. Waite and I proved by actual observation on cadavers fitted for the work. The three theories as to the origin of the mesentery may be stated in short as: a, coalescence; b, displacement; c, independent origin from ridges of cells.

It may be stated in regard to the coalescence theory, that coalescence or union of surfaces by absorption on epithelial cells is at least not usual. The theory of displacement or readjustment is based on the fact that the viscera grew faster than their envelope, the peritoneum, and as far as the theory which attributes the origin of the mesentery to the heaped up ridges of mesoblastic cells situated on each side of the vertebral column, much may be said in its favor. The best sample to illustrate the displacement theory of the mesentery is that of the descending colon. The rapidly growing kidney pushes itself between the meso-colon-descendens and makes according to this view, the external layer of the meso-colon overlap the parietal layer; the folds disappear by coalescence of its epithelium. The advocates of this theory claim that a white line of coalescence can be found parallel to the descending colon, which, it is claimed, proves the correctness of the theory. Microscopic examination would not prove anything because after the coalescence there would be no epithelium left to tell the story of coalescence. This theory, which will be contested in the present work is also put forth in regard to the great omentum. The small pits and pockets found along the ascending and descending colons are referred to as proof of the coalescence theory. I have examined them and do not consider them due to formation of the mesentery by coalescence. I think they are due to old peritonitis. I have found such pockets which would admit the finger point, but sufficient evidence existed to demonstrate an ancient peritonitis. The displacement or readjustment theory of the mesentery has many points in its favor. It must be considered that the peritoneum and bowel develop, hand-in-hand. The peritoneum is an integral part of the viscera and grows with them. The essential condition of existing viscera is peritoneal covering. As the viscera grow irregularly the peritoneum will need readjustment. For example, the cecum grows rapidly while the appendix atrophies rapidly, hence here a vast readjustment of peritoneum is required and it is accomplished without a break in its surface. The typical readjustment or displacement of mesentery

is observed when the growing kidneys steal away and appropriate the meso-colon ascendens et descendens. When any viscus grows faster than its covering or faster than its adjacent neighbors, some form of readjustment or displacement must arise. It appears to me that the statement so generally made by writers that the change from primitive to secondary mesenteric insertions, as being wholly due to secondary coalescence is not all true, but that readjustment or displacement tells a large story. The mesentery may not be a conjoint visceral fold, but a neuro-vascular pedicle arising out of the collection of mesodermic cells situated immediately on each side of the notochord and finally becoming modified, being faced by epithelium.

It may be asked, Why is the mesentery inserted only on the dorsal wall? It is no doubt due to the immobility and rigidity of the dorso-abdominal wall. If the wall were movable no mesentery could insert itself. The liver and kidneys aid in immobilizing and fixing the mesentery. Whatever theory is held as to the development of the mesentery, this must be borne in mind, that the serous cavities are due to interstitial fluid pressure and independent action of the adjacent walls. Connected with visceral cavities are generally mesenteries, more or less complicated, whose insertions are on the most fixed walls.

The blood vessels of the mesentery are single large trunks at the roots. In fact, three blood vessels supply the whole digestive tract—the gastric supplies the stomach, the superior mesenteric supplies the whole of the small intestines, except the duodenum, and from the middle of the transverse colon to the cecum, and the inferior mesenteric artery which supplies the left half of the transverse and the descending colon. As the gastric reaches the stomach it divides, and supplies the smaller curvature and the esophagus. It does not make anatomic arches and loops. The superior mesenteric artery arises like the gastric as a single trunk, but it soon begins to branch. In early embryonic life, before intestinal rotation, the branches passed to the right, but after rotation the branches pass from the left side of the superior mesenteric artery. These branches, ten to fifteen in number, are designated the vasa intestini tenuis. Shortly after the branches of the superior mesenteric artery pass off from the main trunk they begin to anastomose with each other, forming arches and loops. In the vasa intestini tenuis, I have counted as many as five distinct series or rows of loops. The anatomic loops lessen in size as they approach the bowel and the artery rapidly lessens in caliber. The general number of anatomic loops is three or four, which wonderfully equalizes circulation for different sections of the digestive tube allowing unequal demands of blood. As the arterioles leave the anastomotic loops they run for a short distance parallel and on reaching the wall of the gut they bifurcate and encircle the bowel, making vascular rings. The vasa intestini tenuis supplies the mesentery itself with its glands and nerves.

The superior mesenteric artery offers many variations. I have seen it give a branch to the liver. It may take the place of the inferior mesenteric, as it does in many lower vertebrates. It may give branches to the stomach and spleen. Its vasa intestini tenuis may vary in number, size and loops. Hyrtl, in his "Lehrbuch," 17th Ed., 1884, describes a persistent amphalo-mesenteric artery. In this case

it supplied the rectus abdominalis, anastomosing with the deep epigastric, and finally passed into the suspensory of the liver along the round ligament. By care and patience, one can dissect out almost the whole of the superior mesenteric artery in subjects prepared for the work.

The inferior mesenteric artery arises from the abdominal aorta about one and one-half inches above its bifurcation. It supplies the large bowel from the middle of the transverse colon to the anus. It forms anastomotic arches, similar to the superior mesenteric, but less in number and fewer in series. The inferior mesenteric artery may vary in its points of origin. It may be entirely displaced by the superior mesenteric artery. Some anatomists note that it may give off a middle colic. It has been noted to give off branches to each umbilical artery. Walsham writes that the anastomosis between the middle and left colic arteries may be wanting, as is the normal condition in the ruminants and porcupine. "Quain" announces that it may give branches to the liver and kidneys, and Hyrtl saw it arise from the common iliac. A peculiar point in regard to the inferior mesenteric artery is that it has close relations with the rectum whose veins anastomose with the portal veins. Hence, blood from the rectum can go directly to the liver by way of the portal vein. The portal vein collects blood from the digestive tube and carries it to the liver. Now it is observed by all who pay especial attention to the peritoneum and its development, that blood vessels make various projecting folds in its mesenteries. The vessels project the peritoneum into a ridge, and accompanying this ridge are found corresponding depressions. The arteries which are manifest in their production of ridges in the peritoneum are the ileo-colic which produces the plicæ ileocecalis, superior and inferior. The ileo-colic sinistra and sigmoidea produce wide depressions between the large branches and also among its sigmoid vascular arcades. I have noted depressions one and one-half to two inches in diameter and nearly two inches wide in the vascular arches of the sigmoid. One could push this sac-like pouch toward either side of the sigmoid mesentery. Such wide depressions might have been produced by pressure, *e. g.*, the rapidly growing kidney at its lower end, by its projecting against the sigmoid mesentery. The long sigmoid might have been displaced against some round projection, *e. g.*, against the liver, a coil of intestine or the bladder, when the sigmoid mesentery was very thin, yielding and distensible. The gastric artery makes a very prominent fold of peritoneum projecting into the lesser omental cavity. This is no doubt what Huschke tried to describe as the gastro-pancreatic ligament or omentum. In one adult which Dr. Waite and I carefully examined, the fold over the gastric artery projected more than an inch into the lesser omental cavity. This fold gave a distinct border to the foramen of Winslow on the left.

(To be continued.)

**Ocular Diphtheria Treated by Antitoxin.**—Dr. Coppez, in a Brussels medical journal had a good result in one case: "The membranes," he says, "seemed to melt like a snowflake in a ray of sunlight." It may reasonably be expected that the invading progress of pseudo-membranous exudation may be early checked by this treatment. "Or, better still," says Dastot, "the last two stages of the malady may be suppressed—with all the dangers that attend them." Twenty-four hours should see the subsidence of all menacing symptoms.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, APRIL 20, 1895.

A PROPOSED STEP BACKWARD.

We are advised by a reliable authority that the College of Physicians and Surgeons of Baltimore, Md., have filed a proposed amendment to the constitution of the Association of American Colleges, which if adopted, would undo the good work accomplished at San Francisco, providing that graduates after 1898 shall have attended four courses of lectures, in different years, before receiving the degree of M.D. In view of the decided action taken upon this question by the AMERICAN MEDICAL ASSOCIATION at Detroit, and in fact since its organization, we feel it our duty to protest against the position taken by the Baltimore college. In this protest we believe we shall have the sympathy and support of 99 per cent. of the profession of America. There can be no doubt of the attitude of the profession to-day. This was well illustrated in the adoption of the RAUCH resolutions by the AMERICAN MEDICAL ASSOCIATION at Detroit, providing that parties holding diplomas of later date than 1890 must have attended at least four courses of lectures before receiving a degree, in order to secure membership in this ASSOCIATION. The resolution was adopted *unanimously*. The four-year amendment was adopted by the College Association at San Francisco by a vote of 17 to 5, and afterwards ratified by a unanimous vote. Minnesota has amended her medical law, requiring attendance upon four courses before admitting parties to an examination to begin practice. The Iowa Board of Health has adopted the four-year minimum of requirements, as well as several other States. The repeal of the San Francisco amendment will be far-reaching in its pernicious influences upon both the profession and the colleges. The present is

a period of evolution in methods of medical education in this country; all signs pointing toward an immediate solution of higher medical education in the United States. We had hoped to be soon relieved of the repeated jibes of the foreign medical press, that have for years taunted us upon the question of medical education. The JOURNAL appeals to the colleges of the country to immediately carry into execution the provisions of the four-year course. A failure to do so will result in humiliation and disgrace. It is needless to discuss this question from a professional standpoint as the arguments are one-sided. Upon investigation it will be generally conceded that no valid argument can be afforded in favor of a repeal of the present provisions of the College Association calling for attendance upon four courses of lectures before conferring the degree of M.D.

We can not believe that the better judgment of the College Association will permit this backward move; and as the statistics show that the colleges of the highest requirements are now having the largest and best classes, we think the matter of self-interest will have a powerful bearing in preventing such a catastrophe.

INSANITY AND LUNACY IN MASSACHUSETTS.

The statutes of Massachusetts are not clear in their use of words applicable to mental disease. They have, for example, provided for the treatment of the insane charges of the State at "Hospitals for the Insane" at Danvers, Northampton, Taunton, Westborough and Worcester. But they are under the government of a State Board of Lunacy. The hospitals are models of their kind and the State Board is a hard-working and efficient body, but the latter has not yet found its way clear to shake off the archaic name. The full title of this Board is "the State Board of Lunacy and Charity." Its membership is nine, and its members serve without salary. Its powers and duties are vast and far-reaching. In addition to the insane class, it has to do with almshouses, the State farm, three State schools, juvenile offenders, the boarding out of infants and other minor wards, non-settled paupers, pauper statistics, bastardy among the unsettled, immigrants falling into distress during their first year, and visiting the sick poor. The visitation of young girls boarded out in families, is conducted by eighty-one carefully selected lady visitors who reside near enough to their wards, to be cognizant of their needs and the manner of treatment; these ladies receive no salary. The board has been in existence about sixteen years, in which time there have been only thirty appointments, only two deaths and only nineteen resignations. It speaks creditably for a non-salaried board to show an average resignation list of only one and a fraction per annum.

### THE ADVANCE OF LABORATORY WORK IN AMERICA.

When LISTER visited the United States in 1876, and spoke on the subject of antiseptics at the International Medical Congress, there was no bacteriologic laboratory in this country. The impetus given to bacteriologic studies by the practical needs of surgery was first felt in Europe, but although there were many in the field, it was not until the improved methods of laboratory technique had demonstrated bacillus tuberculosis, and the comma bacillus, that the immense practical value of this department of science dawned on the medical world. America was fully aroused and almost simultaneously there sprung into existence laboratories in connection with Harvard, Johns Hopkins, the Hoagland in Brooklyn, the Carnegie, the Loomis, the Chicago Medical College and the Universities of Pennsylvania, and Michigan, and the medical colleges throughout the United States soon found it necessary to give instruction in bacteriology and to provide suitable equipment therefor.

Naturally, independent investigators were developed by the new and interesting fields of discovery that opened before the vision of the enthusiastic workers. STERNBERG of the Army, WELCH of Johns Hopkins, PRUDEN and BIGGS of New York, BELFIELD of Chicago, COUNSELMAN and SHAKESPEARE were among the earlier of the observers.

Europe, in advance in the original discovery, again led in the new chemico-departure made necessary by the investigations of METSCHNIKOFF and his colleagues, showing the life history of bacteria, and the pathologic changes produced by the microbic products. American bacteriologists in general were not well prepared for this chemico phase of the subject, but the name of VICTOR C. VAUGHAN stands pre-eminent among the first of our bacteriologic chemists. He was well prepared for this work, by his discovery of the tyrotoxicon and other ptomaines. To-day it is fair to assume that organic chemistry and bacteriology are as well understood in America as in Europe, and that there are a dozen laboratories in which any experiment made in Europe, may be tested with scientific exactness.

Nor is the work of our American laboratories merely imitative. We have passed beyond that stage and the original work of STERNBERG, KINYOUN, THEOBALD SMITH, CHITTENDEN, COUNSELMAN, ERNST, EINHORN, OHLMACHER, ABBOTT, MCCLINTOCK, LONG, GEHRMAN and others, is as closely watched in Europe, as we ourselves watch the European observers.

In the field of chemico researches in our laboratories outside of bacteriology, we have had many observers, but none who have conducted to a conclusion more painstaking investigations in physiologic chemistry and in pathologic substances than JOSEPH JONES, of New Orleans. We can not undertake to

mention all of the distinguished American workers in the wider field of general chemistry, such as SMART, of the Army, REMSEN, of Baltimore, HAINES, of Chicago, but in that field we may point with pride to a long list of expert chemists, and we venture to predict that before the end of a decade, the leadership in laboratory work will be held in the United States. Even as we write, there are more independent original investigators in Chicago alone than there were in the whole United States a decade ago.

The Vermont Microscopical Association announced recently that a prize of \$250 will be given by the well-known chemists, Wells & Richardson Company, to the first discoverer of a new pathogenic germ. We shall be disappointed if this prize is not awarded to one of our countrymen. C. SMITH BOYNTON, M.D., of Burlington, Vermont, will furnish any information concerning this prize, on application.

### THE NOMENCLATURE AND CLASSIFICATION OF DISEASES IN THE NAVY.

In our issue of March 23, we published the new official nomenclature and classification of diseases and injuries, directed to be used hereafter by the medical officers of the Army by order of the Surgeon-General, promulgated in Circular No. 3 of March, 1895. It is interesting to compare this with the nomenclature and classification which went into effect on January 1, of this year in the Medical Department of the Navy, by order of the Surgeon-General of the Navy, issued some months before, which we print in this issue.

The naval classification preserves the technical Latin and Greek nosological titles, carefully revised on the ground of facilitating statistical comparison with similar returns by foreign services. The Army system employs English, Latin and Greek designations indiscriminately. Thus, glycosuria, gout and scurvy appear among Army titles, the corresponding Navy names being diabetes, lithemia and scorbutus. Instead of measles and röteln in the general infectious class of the Army, the Navy has morbilli and rubella.

There are 330 titles on the Navy list against 249 in the Army, but as 19 of the latter are duplicated, appearing under different classes, and as 12 numbers are given to the expression, "other diseases of this class," there are really only 218 specified diseases and injuries in the Army nomenclature.

Class I, Parasites and Parasitic Diseases of the Navy list has not been retained by the Army, trichinosis being classed by the latter with the general infections and scabies and the dermatophyta with local infections. Carcinoma and sarcoma are placed among general infectious diseases in the Army list, and appear among cysts and new growths, Class XII, Navy list.

Venereal diseases, which the Army retains among the general infections, are transferred by the Navy to Class XI, entitled venereal diseases and diseases of the genito-urinary apparatus.

Debilitas senilis, hemophilia, purpura hemorrhagica and purpura simplex in the Naval Class III, of constitutional diseases of nutrition are not enumerated in the Army Class II, diseases of nutrition, general.

The several classes: IV, Diseases of the Nervous System; V, of the visual apparatus; VI, of the auditory apparatus; VII, of the olfactory apparatus; VIII, of the nutritive apparatus, with subsidiary classes 1, of the Digestive Apparatus; 2, of the Circulatory Apparatus—A, Blood Vessels; B, Lymphatics; 3, of the Respiratory Apparatus. IX, of the Motory Apparatus; X, of the Cutaneous Apparatus; XI, Venereal Diseases and Diseases of the Genito-Urinary Apparatus are all included by the Army in one general Class III, Structural and Functional Diseases of Organs, under the subordinate heads: A, Diseases of the Nervous System; B, of the Digestive System; C, of the Circulatory System; D, of the Respiratory Organs; E, of the Genito-Urinary System; F, of the Lymphatic System and Ductless Glands; G, of the Muscles, Bones and Joints; H, of the Integument and subcutaneous Connective Tissue; I, of Organs of Special Sense; (a) of the Eye, (b) of the Ear, (c) of the Nose.

Accidents and Injuries IV, and Unclassified, V, complete the Army classification, while the Navy has XII, Cysts and New Growths; XIII, Injuries; XIV, Extraneous Bodies; XV, Poisons; and XVI, Feigned Diseases.

A few other minor differences between the two may be indicated. Thus, nostalgia appears among diseases of the nervous system (Army) but it is not specified in the Navy, and directed to be included under the title, melancholia. Nausea marina, for which it is to be regretted the more exact title naupathia, has not been substituted, is classified with diseases of the nervous system by the Navy, and rabies with general infections, neither appearing in the Army classification. Insolation among general injuries (Army) is more appropriately classed as febris thermica and prostatic thermica among diseases of the nervous system (Navy), along with febris continua simplex and febris ephmera, which have no place on the Army list, except among fevers of undetermined causation in Class I, General Infectious Diseases. On the other hand, the Army places narcotic poisoning, acute and narcotic poisoning, chronic or drug habit among diseases of the nervous system, while they are not mentioned in the Navy list, but would by analogy be reported among other diseases of Class XV, Poisons. Cholera morbus and dysentery are classed as diseases of the digestive system (Army)

and among general infectious diseases (Navy). Cardiac irritability and cardiac degenerations are enumerated among diseases of the circulatory system (Army) and not mentioned on the Navy list. Anthrax appears among the general infections and carbuncle among the local infections (Army), and carbunculus only among diseases of the cutaneous apparatus (Navy). There are twenty-nine diseases of the visual apparatus specified on the Navy list and but fifteen diseases of the eye on the Army list. The classification of neither Service includes herpes zoster and ulcus perforans, although the nervous origin of both diseases which are of frequent occurrence is well-established.

The Marine-Hospital Service has for many years followed literally the nomenclature of the Royal College of Physicians of London, a revision of which is now due.

#### COLLECTIVE INVESTIGATION OF THE ANTITOXIN TREATMENT OF DIPHTHERIA.

When PROFESSOR VIRCHOW—repudiating the attack of his assistant, DR. HAUSEMANN, on BEHRING'S theory of the serum treatment of diphtheria—said: "All theoretical considerations must give way to the brute force of these figures," referring to the statistics of the treatment in the Kaiser and Kaiserin Friedrich Hospital of Berlin, the question seemed to be settled as to the general merits of sero-therapy. During a given period 533 cases of diphtheria were treated in this hospital; of these 303 were treated with the serum, with a mortality rate of 13.2 per cent.; 230 were treated without serum, with a mortality rate of 47.8 per cent. A still more striking exhibit was afforded during June and July, when nearly all cases were treated with the serum and the mortality rate was 12.7 per cent. "Suddenly," says VIRCHOW, "the supply of serum ceased, as, unfortunately, the very horses from which the serum was taken died. The old methods of treatment had again to be resorted to and the results were"—109 cases, 55 deaths in seven weeks, a mortality rate of 50.46 per cent. A supply of serum was then obtained from another source, and during the next six weeks 81 cases were treated with 12 deaths, a mortality rate of 14.81 per cent. It was the "brute force of these figures" which VIRCHOW said compelled him to recommend the serum; to attribute to it "a brilliant therapeutic virtue;" to contend that, even if disagreeable by-effects were proved to occur occasionally, they were not sufficient to deter him from continuing the treatment; and to counsel that the theoretical explanation of its therapeutic action should be left to the future rather than allow the failure of such explanation to interfere with its practical application.

Since then, however, these and similar figures which seemed so convincing have been rudely assailed.

Among the most recent of the assailants is DR. JOSEPH E. WINTERS, of New York City, of whom the *Medical Journal* says: "Nobody who knows the medical profession of New York can question DR. WINTERS' astuteness as a clinician and we do not conceive it to be possible to bring up any circumstance or condition that may reasonably be held to have tended to warp his judgment in this matter." At a recent meeting of the New York Academy of Medicine (April 3) DR. WINTERS, discussing the papers presented on diphtheria and the antitoxin by DRs. HERMANN A. BIGGS, W. H. PARK, C. H. PECK, GEORGE P. BIGGS and IRA VON GIESEN, sweepingly challenged every claim made for sero-therapy, attacked the favorable statistics and alleged a number of serious after-effects due to antitoxin septicemia. In an experience of 154 cases treated during January, February and March, 1895, in the Willard Parker Hospital he asserted he had never found that the serum exerted the slightest influence for good on a single clinical manifestation—on membrane, pulse, temperature, gland swelling, laryngeal symptoms, etc. "Every one of these patients had been examined daily; they had been examined with care and with great solicitude and with the desire to discover some evidence of the virtues ascribed to antitoxin by others." He further opposed antitoxin on account of its "immediate danger to life through its influence on the kidneys and on the nervous system and remotely through its influence on the blood"—basing this last charge, apparently, on the destructive action of horses' serum on the red globules, as reported by L. LANDOIS and others.

Again: PASSED ASSISTANT SURGEON CORDEIRO, U. S. N., has just reported to the Surgeon-General of the Navy the results of his study of the use of antitoxin in the Berlin hospitals, and concludes that "so far, proof is lacking of the value of antitoxin in the treatment of diphtheria;" he adopts the adverse opinions of KASSOWITZ who says: "The burden of proof lies with BEHRING and his co-workers. The world will eagerly and only too willingly receive this proof. We know that the former extravagant promises are out of the question, but we should be grateful to have it demonstrated that the serum can reduce the mortality by even 1 per cent. As yet we have not the slightest basis on which to found an expectation that fewer children will die in the future of this disease on account of the serum treatment."

In this conflict of opinion there is, obviously, an urgent necessity for the collected and collated experience of the profession, and the JOURNAL offers itself as the medium for the collection of this experience. Following the last page of reading matter in this issue, will be found a blank form for reports of cases of diphtheria, treated either in hospital or private practice. In order to facilitate comparison with the experience in other countries, this form has been

prepared in close accord with that now in use in Germany for the collective investigation undertaken by the *Deutsche Medicinische Wochenschrift*.<sup>1</sup> This blank form is believed to be self-explanatory; it may be detached without mutilating the rest of the number; and it is hoped that all members of the AMERICAN MEDICAL ASSOCIATION who have had or may have any experience in the antitoxin treatment will contribute to this attempt to settle the question of its merits.

#### SECTION ON BENEVOLENCE.

Our friend DR. FREDERICK HORNER, U. S. N., retired, writes us concerning the plan he has often urged, whereby a fund may be created for the relief of widows and orphans of medical men. He urges the establishment of a "Section on Benevolence" or "Medical Aid Section," reference to which was made in the JOURNAL for May 16, 1891, and April 16, 1892.

It is understood that our President, DOCTOR MACLEAN, will this year favor the matter, and ask that the initial steps be taken for inaugurating the measure.

By a resolution of the ASSOCIATION, passed at Washington in May, 1891, a committee was authorized to be appointed on the subject, but it appears that no report was made, although the exhaustive paper of DOCTOR HORNER (see JOURNAL, April 16, 1892, p. 482) might very well answer such a purpose.

We sincerely hope some definite action may be taken at the Baltimore meeting, which will result in the establishment of some such section.

THE JOURNAL TRAIN from *Chicago* for *Baltimore*, Sunday, May 5, 3:15 P. M., via Pennsylvania Railroad, is a *special* train, exclusively for the use of the members of the ASSOCIATION and their friends. It goes direct to the place of meeting, on limited time and with the finest train service in America. There is but one JOURNAL train, and that is via the Pennsylvania R. R.

PAPERS READ IN THE SECTIONS.—Members are respectfully reminded that papers read before the Sections become the exclusive property of the ASSOCIATION.

#### CORRESPONDENCE.

**Shall Ingenuity and Invention be Discredited Among Physicians?**

DENVER, COLO., April 9, 1895.

To the Editor:—The above is practically one of the important questions which should have been decided at last year's meeting in San Francisco. Could it have come to the surface so as to have been voted on separately, the indications were then that the proposition to change the Code in this particular would have carried by a large majority. Happily, Dr. Quimby, of New Jersey, put in an amendment, separately from all others proposed, which brings this question

<sup>1</sup> The JOURNAL is indebted to the courtesy of DR. JULIUS SCHWALBE, one of the editors of the *Wochenschrift*, for a copy of the return blank.

squarely before the Baltimore meeting. Dr. Quimby's motion is to "change the Code of Ethics—Duties for the Support of Professional Character—by leaving out the words 'Surgical Instruments,' in second line, Clause 5, Article I."

To spare the precious time of the meeting and to "hedge" against the possibility of my not being able to be present when this question comes up, please allow me to give a few reasons why this change should certainly be made, and the mechanical device or "surgical instrument" be forever divorced from the low company of "a secret nostrum."

As a preliminary let me observe, with all due respect for our professional grandmothers who framed the Code and Constitution of the AMERICAN MEDICAL ASSOCIATION, that the horizon of their vision of the possibilities of invention must have been rather narrow. The conditions were so different then from what they are now. Then, with few inventions made by medical men, and few patents issued to anybody, there was no need apparent to protect any physician in his right to be honored as the originator of anything. Now there is every need, and the Patent Office is the only reliable criterion by which to decide if a man has even made an original invention. To require that a man should prove his title and then deprive him of the only means of so doing reminds one of that old college song:

"Mother, may I go to swim?"  
"Yes, my darling daughter;  
Hang your clothes on a hickory limb,  
But don't go near the water."

The question is not whether it will pay for a physician to take out a patent on an invention. Judging by the forty-five thousand or more patents already allowed in the United States, and only one in fifteen a financial success, it would probably not pay, and the applicant would have a "heap of bother" and considerable expense in return for the establishment of his own originality and a possible service he may do his fellow men.

Briefly stated, the arguments which seem to me sufficient to warrant this proposed change in the Code are:

1. That the intrusion of the words "surgical instruments" is uncalled for and without good excuse. It is out of harmony with the rest of the paragraph, for *there is no fraud or secrecy to be avoided*, as implied with regard to "secret nostrums." The latter are generally known to be cheats, while the former bear "upon their face" their evidence of worth and fitness.

2. The interdiction of "surgical instruments," and by implication probably (?) mechanical devices, is wrong, because the Patent Office furnishes the only reliable proof that a claimant is entitled to credit.

3. The sacrifice in time, thought and expenditure required of a physician is really a *damage* to the medical profession, not to mention the deprivation to those who depend upon our aid, because many new things must be made, if at all cheaply, by dies and machinery, and manufacturers will demand protection for their own outlay. Especially is this the case with all hard rubber goods which have to be made in expensive molds.

4. The restriction imposed is *unjust* to the physician inventor, because he (co-equal with an outsider) ought to have the stimulus of credit and profit, if there is any, in order to make a success of his invention. The field is the world, and after all the great test of merit is extended use, and the sources of profit must be massed and under rightful control in order to secure such introduction to supply demand. The writer could illustrate this point by the failure of meritorious, mechanical, surgical inventions which have come short of recognition and use because of the lack of properly sanctioned pushing of their undoubted claims upon the attention of those who should employ them. Again he could illustrate a point taken (3) by stating that he has lately been requested to indorse a poor make of his stethoscope, with which it is proposed to undersell the market, and calculated to bring discredit upon an instrument the utility of which, when properly made is unquestioned. And now when he is just finishing an improved stethoscope, made on similar but new lines and measurements, he is warned that he must secure the same by patent, or So-and-So—manufacturers—will cheapen the thing to capture the trade, regardless of his wishes to hold the instrument to an even grade of excellence. What shall be done under such circumstances? Shall the author take the advice given him by two ex-Presidents of the AMERICAN MEDICAL ASSOCIATION and get behind a surgical instrument company who will seek protection from the Government for him? or shall he be open-handed and boldly announce that his own rights in the matter are just the same as those of any citizen of the

United States, even though he *is* a member of the AMERICAN MEDICAL ASSOCIATION?

The best way is to change the blamed paragraph and make it read as though a sane man had originally written it.

Yours respectfully, CHARLES DENISON, M.D.

### The Judicial Council.

PHILADELPHIA, April 10, 1895.

To the Editor:—The JOURNAL of the 6th inst. contains a criticism of the circular, relative to advertisements, recently sent to all members of the AMERICAN MEDICAL ASSOCIATION by the Philadelphia County Medical Society. In the criticism occurs a personal allusion which impels me to request the publication of this letter. The JOURNAL says: "There are two direct mis-statements in the committee's report which we are sure they will be glad to have corrected; one is that the decision of the Judicial Council was not given to them or published. We notice that Dr. John B. Roberts has signed this document, and that he was also Secretary of the Judicial Council. If he failed to notify his associates on the committee of the action of the Council surely the JOURNAL is not to blame."

It is true that I was a delegate of the Philadelphia County Medical Society to the meeting of the AMERICAN MEDICAL ASSOCIATION at San Francisco, and therefore signed the report made by the delegation after its return to Philadelphia. It is also a fact that I was and am the Secretary of the Judicial Council of the Association.

The circumstance that I held the two positions and *could* have disclosed the decision of the Judicial Council to my associates of the delegation, seems to the JOURNAL a sufficient reason for supposing that I *would* do so. Such a betrayal of official confidence would, in my opinion, make me unworthy to be a member of the Council.

As Secretary, I was directed to furnish the Board of Trustees with a copy of the decision in regard to the publication in the JOURNAL of advertisements of secret preparations. I did this immediately, on June 8, 1894. I was not at liberty to inform any one else, outside of the membership of the Council, not even those who brought the charges against the Trustees. I therefore have refrained from doing so.

You will remember that I declined to be present during the executive sessions of the Judicial Council at which the question was considered, because of my official connection with the Society bringing the charges. After the decision of the Council had been made, I returned to the room and resumed the duties of Secretary, which during my absences had been performed by Dr. X. C. Scott, and Dr. T. D. Crothers respectively acting as Secretary *pro tempore*.

Yours truly, JOHN B. ROBERTS, M.D.

ANSWER:—The *decisions* of the Judicial Council are not secret. The *proceedings* are secret, but not the *decisions*. The copy sent the Trustees was signed by Dr. Roberts.

### Mountain Air for Cities.

MILTON, KY., April 15, 1895.

To the Editor:—The details of the plan which I suggested in the JOURNAL of March 30, for supplying pure air to cities are as follows: Upon a sufficient foundation is a frame thirty feet high, within which is an elevator running to top of frame, for the purpose of raising the perpendicular sections of steel plate pipes, each of which is twenty feet long, and each one is larger than the one above it, to which it is securely bolted, and also of heavier plate. When the first two joints are securely joined at the top of frame they are elevated until another is added and so on until the first attains the desired height. Guys are attached and are so arranged as to maintain the pipe perpendicularly.

Electric lights could be attached to the top of the pipe, and being at an elevation of six hundred feet would be at least quite conspicuous.

The lower end of the pipe is attached to the cylinder of a pump which draws the air down through the pipe and forces it through the supply pipes to the desired apartments. These rooms should be practically air-tight except the ventilator at the lower, and the supply pipe at the upper part of the room. The air from an altitude of six hundred feet, being so much lighter than the impure air at the surface of the earth would force the latter out of the room, the temperature of which could be regulated by passing the supply pipes through either cold or hot media. A room thus furnished and covered with glass would be an ideal mountain resort.

It is believed by some that pathogenic microorganisms, other than the tubercle bacillus, play an important part in the destruction of lung tissue. In view of the facts that during sleep the vital resistance of the system is greatly lessened and that the air in all large cities contains innumerable hosts of ferocious pathogenic microbes, the wonder is that there not more pale, wan faces in cities, or even that there should be any one left to tell the tale.

It is even hinted that the tubercle bacillus alone is unable to cope with the vital resistance of the system. Hence we send our consumptives to a high dry location for pure air. But with my plan a high dry location with absolutely pure air is sent to our consumptives.

Not only the apartments for invalids but also factories, business offices, store rooms, etc., could have the mountain air, simply by making the upper part of the rooms air-tight.

I have thus briefly outlined the plan for supplying cities with pure air of any desired temperature at a trifling cost compared with the benefits to be derived, and I hope to see Chicago—the wonder of the nineteenth century—take the lead in making a test of its practicability.

S. E. HAMPTON, M.D.

### Quis Custodiet Ipsos Custodes?

CHICAGO, April 13, 1895.

To the Editor:—At a meeting of the faculty of the Northwestern University Woman's Medical School, the following resolutions were unanimously adopted and ordered to be placed before the Illinois State Board of Health:

WHEREAS, On three occasions within the past three years, the Illinois State Board of Health has licensed to practice medicine in this State, students who have not properly qualified themselves for such duties, and whose incompetence has compelled us to withhold the degree of Doctor of Medicine; and

WHEREAS, By common report we are informed that the State Board has adopted a similar policy with reference to numerous other persons; therefore,

Resolved, By the faculty of the Northwestern University Woman's Medical School that the State Board be requested hereafter to make its examinations so rigid that persons incompetent to obtain the degree of Doctor of Medicine from first class medical colleges can not obtain license to practice from the Illinois State Board of Health.

Resolved, That the State Board of Health be urged to do all in its power to secure a modification of the State law, so that the privilege of examination for license to practice in this State can only be obtained by graduates of recognized medical schools in good standing.

Resolved, That for the protection of the lives and health of our people, we believe it the duty of the State Board of Health to do all in its power to prevent the entrance into the medical profession in this State of any persons not properly qualified; and further

Resolved, That in the interests of humanity and medical science we believe the State Board should make its standard of qualifications as high as that of the best medical colleges in this country, and that it should do all in its power to aid and encourage the efforts of the profession and the people for thorough medical education and higher requirements of licentiates and for the degree of Doctor of Medicine.

MARIE J. MERGLER, Secretary.

### Shall the Physician Act as Clerk for an Insurance Company without Pay?

STOUGHTON, Wis., April 11, 1895.

To the Editor:—I inclose a copy of a letter I wrote to the Wisconsin Benevolent Association which is self-explanatory: Wisconsin Benevolent Association, Milwaukee, Wis.

Gentlemen:—Your letter of the 11th inst. at hand. Your statement does not in the least alter the position I have taken.

I filled out the blank sent to the patient, giving my diagnosis, number of visits, date of first and last visits, the time patient was confined to the house, etc. This is about all that is required of the attending physician, without compensation, by any legitimate accident insurance company and is amply sufficient to establish the justice of the claim so far as the testimony of the attending physician is concerned.

The filling out of a complicated blank, such as you inclose, requires time and technical skill, is exclusively for your benefit, and is not under any consideration justly chargeable to the patient. The patient has paid you for the insurance;

he has also paid me for the medical services rendered during his recent illness. It is therefore manifestly unjust, even if it were possible, to collect from him an additional fee for an examination and written report which is solely for your benefit. It is impossible for me to answer questions you put in your report without making a much more thorough and complete examination than is required in an ordinary case of a slight acute attack of sickness. Take for instance the question: "Were there indications of disease of the blood vessels?" Now it is no easy matter to determine this, and the question can not be truthfully answered until it is determined. The same is true regarding the question asking whether the patient has had any disease of the kidneys, liver, lungs, heart, etc. To even make a diagnosis of exclusion requires a careful and painstaking physical examination of the patient, a chemie and microscopic examination of the urine and the excretions generally. You can readily understand that this takes time and skill. If I am to answer these questions by guessing at it, you are about as competent to do that as I am.

I have consulted an excellent attorney regarding this matter and am prepared to sustain the position taken at all hazards. There is no way by which you can compel me to give you the benefit of my knowledge and experience without adequate compensation. Very respectfully yours,

J. NOER, M.D.

### Antitoxin.

CHICAGO, April 13, 1895.

To the Editor:—In an editorial of the April 13 number of the JOURNAL, you refer to the case of Bertha Valentine, of Brooklyn, who died ten minutes after the injection of Behring's antitoxin No. 2, Op. 159, tested Jan. 30, 1895. April 5, I used Behring's antitoxin, No. 2, 1,000 and No. 2, Op. 159, tested Jan. 30, 1895 (note the coincidence of the Op., please), upon a 4-year-old boy with surprisingly good results. This seems to me but another link in the chain, showing that the cause of death was not inherent in the antitoxin used; for that used by me was from exactly the same lot of serum and cured, not killed, my case. It might be well to hear from every case upon which Op. 159, Jan. 30, 1895, test has been used.

Trusting that my contribution will help dispel the prejudice aroused by this deplorable case, I am,

Yours respectfully, ROSA ENGELMANN, M.D.

ANSWER:—This letter is itself evidence of the necessity of the collective investigation proposed by the JOURNAL.

### Fairfield County (Conn.) Medical Society.

WESTPORT, CONN., April 10, 1895.

To the Editor:—At the one hundred and third annual meeting of the Fairfield County Medical Association, held in Bridgeport, April 9, the following officers were elected: F. B. Baker, East Norwalk, President; J. W. Wright, Bridgeport, Vice-President; L. T. Day, Westport, Clerk; C. R. Hexamer, Stamford, Corresponding Reporter. Censors: F. M. Wilson, Bridgeport; M. V. B. Dunham, Greenfield Hill; W. S. Watson, Danbury. Very truly yours, L. T. DAY, Clerk.

### Nu Sigma Nu Convention—Amended Date of Meeting.

DETROIT, MICH., April 12, 1895.

To the Editor:—In my letter to you of March 7, having inclosed a notice of the Nu Sigma Nu Medical Convention for the JOURNAL's last issue, I gave the dates of meeting in Minneapolis as May 13, 14 and 15. The date has since been changed by Grand Council to June 3, 4 and 5, 1895. So please make the correction, and oblige. Very truly yours,

JOHN L. IRWIN, M.D.

### ASSOCIATION NEWS.

#### The Forty-sixth Annual Meeting.

It is the desire of the Committee of Arrangements to issue a complete program of the proceedings for each day, in advance of the meeting. Secretaries of Sections should at once send to the chairman of the Committee on Printing, Dr. W. A. B. Sellman, No. 5 E. Biddle Street, Baltimore, Md., the titles of all papers to be read in their respective Sections, in the order in which they desire them to be read. Titles not received before April 20 can not be entered on the program.

The hours for Section meetings will be from 3 to 6 p.m. Some of the Sections will also hold sessions from 9 to 11 a.m. All the sessions will be held in Music Hall. The rooms for the different Sections will be designated on the program.  
 GEORGE H. ROHE, Assistant Secretary.

### The Rush Monument Committee.

The annual meeting of the Rush Monument Committee will be held in the Stage Reception Room, Music Hall, Baltimore, on Tuesday, May 7, 1895, at 9:30 a.m. Members of the Committee are requested to be prompt in attendance, to receive the reports of the Chairman and Treasurer.

In this connection, attention is called to the importance of more active exertions on the part of the members of the committee to raise the necessary funds to erect the monument to this distinguished physician and patriot. The Committee has now upward of three thousand dollars in hand toward this object. One of the latest contributions to the fund (1 guinea) was received from the eminent English alienist Dr. Daniel Hack Tukey, whose death has just been announced. In a letter to the secretary of the committee, Dr. Tukey manifested a deep interest in the success of the enterprise, and expressed some surprise that the American medical profession had been so slow in the erection of this well deserved memorial to one of our medical heroes. I may be permitted here to quote the opinion of Dr. Tukey concerning Rush:

"I am glad to be permitted to contribute my mite to the memorial in honor of one I have always greatly admired. It must be confessed that the medical profession of your country has been tardy in publicly recognizing the claims of their most celebrated physician. I paid my humble tribute to his memory in 'The Insane in the United States and Canada,' and can only regret that I have not sufficient command of language to describe adequately his originality, his talent, and above all his devotion to the best interests of our race, including the insane. In the union of medical skill with active benevolence, I think, as I have said in my book, he was the prototype of Fothergill rather than of Sydenham."

To these eloquent words of the distinguished English alienist nothing need be added. We can not however, afford to continue to rest under the imputation that the American medical profession does not appreciate the greatness of the character of Rush, and it is hoped the contributions toward the memorial will be generous at the coming meeting of the Association.

A table will be placed in the lobby of the Music Hall during the meeting, at which subscriptions will be received.

GEORGE H. ROHE,  
 Secretary Rush Monument Committee.

**Section on Physiology and Dietetics.**—Chairman, E. H. Woolsey, Oakland; Secretary, C. G. Chaddock, St. Louis. Executive Committee: I. N. Love, St. Louis; W. T. Bishop, Harrisburg; Ephraim Cutter, New York.

1. On Food and Thrombosis, by Ephraim Cutter, New York.
2. Physiologic Treatment of Tuberculosis by Injection of Serum, by Paul Paquin, St. Louis.
3. Vital Resistance to Disease, by G. W. Finley, Harmony, Ind.
4. Researches in Rapid Photography by means of Edison's Kinetograph, and the animated reproduction by the kinetoscope; showing also by this method the present and future possibilities of taking and reproducing certain animated physiologic movements of the larynx, heart, intestines, etc., and certain diseases having visible symptoms, etc.; with an historical of fifty years of photography, by J. Mount Bleyer, M.D., F.R.A.M.S., Naples, etc., New York.
5. The Influences of Atmospheric Electro-Barometric Oscillations, by John North, Toledo.
6. The Physiologic and Pathologic Effects of Electricity, with some results of Practical Experience with Electricity, by E. H. Woolsey, Oakland.

### The Baltimore Meeting.

Indications point to a large and enthusiastic meeting of the AMERICAN MEDICAL ASSOCIATION at Baltimore in May, and we do hope that the questions that have been agitating this body for so long will be definitely settled.

What we want is more scientific work, and less squabbling and dickerings over ethical matters.

It is common rumor that some of the members from

Philadelphia and Pennsylvania intend going in force to demand the elimination of advertisements of proprietary medicines from the pages of the JOURNAL, and dire threats are uttered that if their request is not granted they will do awful things—even retire permanently.

We express the hope that this rumor is not true, but if true, these men ought to realize the fact that the Association will not be swayed by threats, or bulldozing of any kind.

If the JOURNAL is to be kept on its feet, all legitimate revenue should be derived from every source obtainable, and this source, which is perfectly legitimate and proper, should be utilized to its fullest extent.

Don't handicap the Trustees, but give them full rein to do as they deem best. They are not the kind of men to betray any trust the Association may impose upon them.

Under Dr. Hamilton's able editorship the JOURNAL has so improved that it is scarcely recognizable. He has given us a first class JOURNAL and his hands should be upheld.

Let us all put our shoulders to the wheel and make this meeting at Baltimore the banner one.—*New England Medical Monthly.*

### Executive or Business Committee.

The first meeting of this Committee will be held in Parlor 23, Hotel Stafford, on Monday May 6, at 5 p.m. Subsequent meetings will be held at the same place and hour, unless otherwise ordered by the Committee. It is hoped that there will be a full attendance, in order to properly consider matters which may be referred to the Committee by the Association, and for the transaction of such other business as may seem desirable. L. DUNCAN BULKLEY, M.D., Secretary.

## SOCIETY NEWS.

**Association of Military Surgeons of the United States.**—The fifth annual meeting will be held at Buffalo, N.Y., May 21, 22 and 23, 1895.

The morning session of the first day will be held in the Star Theater at 10 o'clock. The morning and afternoon sessions will be held at 9 o'clock and 2 o'clock daily, in a convenient and easily accessible location to all hotels, which will be made known in a later announcement. The General Committee headquarters will be in the Iroquois Hotel, where provision will be made for registration.

Addresses: An Address of Welcome to the City of Buffalo, by the Honorable Edgar B. Jewett, Mayor; an Address of Welcome to the State, by the Honorable Levi P. Morton, Governor and Commander-in-Chief of the National Guard of the State of New York; an Address on behalf of the Medical Profession, by Dr. Roswell Park, President of the State Medical Society; an Address by the President of the Association, Brig-Gen. George M. Sternberg, M.D., LL.D., Surgeon-General, U. S. A.; the Report of the Committee of Arrangements, by the Chairman, Major Albert H. Briggs, M.D., N.G.N.Y.

The Citizens' Committee of Arrangements has provided an elaborate and pleasing program for this meeting, and extends a cordial invitation to all members and prospective members to be present and participate in all the exercises, social and literary. On Tuesday evening, and also at other times during the meeting, the members of the Association as far as practicable will be entertained by hospitable citizens of Buffalo at their private residences and at various clubs. An informal hand shake and conversazione will be held at Hotel Iroquois from 9 to 11 p.m. On the same evening the Committee of Arrangements will also escort to the theaters all visitors so desiring. On Wednesday evening a reception will be tendered the members of the Association and their friends. On Thursday afternoon, if time and weather permit, a carriage drive to various points of interest in the city. On Thursday evening a promenade concert will be given by the band of the 65th Regiment, N.G.N.Y., and a review and regimental parade by the regiment at the Arsenal. It is anticipated that a hop will follow these exercises. On Friday, leaving Buffalo at 9:30 a.m., there will be an invitation excursion to Niagara Falls, and probably on to Fort Niagara. This trip will afford the members an opportunity of viewing the various points of interest at the great cataract, including the prodigious electric power plant, which is exciting the attention of the industrial and scientific world, also the historic battle-grounds of Lundy's Lane and Queenston Heights, General Brock's monument, the Rapids of Niagara, and other interesting places.

## PUBLIC HEALTH.

**Latest Circular of the New York City Board of Health on Anti-toxin.**—This Board is now producing 20,000 cubic centimeters of serum each week. People unable to pay for the remedy are supplied without charge. The arrangements for the sale of the excess product are not quite complete. The following is the circular that will accompany the flasks and phials:

"The dose contained in No. 1 is usually sufficient when the cases are mild and the remedy is administered within the first twenty-four or thirty-six hours. Phial No. 2 contains the average full curative dose. In very severe cases, or when the treatment is not begun in a very early stage of the disease, or in any case in which improvement is not marked, the dose must often be repeated twice or thrice, depending upon the symptoms, at frequent intervals of from twelve to twenty-four hours. The remedy is administered by deep hypodermatic injections, a special large syringe being preferably employed for the purpose, although an ordinary hypodermatic syringe, carefully cleaned, may be used, the barrel of the syringe being repeatedly filled. Some point on the anterior surface of the body should be chosen for the injection, where there is an abundance of subcutaneous cellular tissue, as the anterior surface of the abdomen or thorax, or the outer surface of the thigh. Before the remedy is administered the skin should be carefully washed with alcohol or some disinfecting solution. The syringe should be carefully sterilized. The solution is rapidly absorbed, and it is better not to employ massage over the point of injection. When children or adults have been much exposed to diphtheria they may be protected from the disease by the administration of from 150 to 300 antitoxin normal units. The protection probably will not last more than three to eight weeks. The earlier the preparation is administered the more certain and rapid is the cure. In suspicious cases of any severity, and in croup cases, it is better to administer the remedy at once and make a culture at the same time for bacteriologic examination for diagnosis, than to delay the treatment until a diagnosis has been made by bacteriologic examination."

**Health Reports.**—Sanitary reports to the Supervising Surgeon-General, Marine-Hospital Service.

## SMALLPOX—UNITED STATES.

Louisiana: New Orleans, March 30 to April 6, 1 case and 1 death.

Maryland: Charles County (near Newburgh), 24 cases and 3 deaths reported, April 10.

Michigan: Detroit, March 30 to April 6, 3 cases.

Missouri: St. Louis, March 1 to 31, 93 cases and 27 deaths; Nodaway, March 1 to 31, 1 case; Lincoln and Pike Counties, March 1 to 31, 20 cases; no deaths reported.

Ohio: Cincinnati, April 5 to 12, 12 cases of smallpox and 1 case of varioloid.

Pennsylvania: Philadelphia, March 30 to April 6, 8 cases of varioloid.

Texas: Fort Worth, March 30 to April 6, 2 cases.

Wisconsin: De Pere, March 23 to April 8, 1 case (supposed to be contracted through rags in a paper mill); Milwaukee, March 23 to April 6, 13 cases, 4 deaths; April 6 to 13, 5 cases, 1 death.

## CHOLERA—FOREIGN.

India: Bombay, March 5 to 12, 1 death; Calcutta, March 2 to 9, 22 deaths; Madras, March 2 to 8, 2 deaths.

Turkey: Constantinople, January 1 to 31, 14 deaths; February 1 to 28, 108 deaths.

## SMALLPOX—FOREIGN.

Arabia: Aden, March 2 to 9, 3 cases.

Ecuador: Guayaquil, March 8 to 22, 4 deaths.

England: Leeds, March 23 to 30, 1 case.

Germany: Prague, March 9 to 23, 13 cases.

Gibraltar: March 24 to 31, 2 cases.

Greece: Athens, December 1 to 31, 1 death.

Havana: Cuba, March 28 to April 4, 10 deaths.

Hungary: Buda-Pesth, March 11 to 25, 3 cases.

India: Calcutta, February 23 to March 2, 123 deaths; Singapore, January 1 to 31, 1 death.

Mexico: Nogales, March 23 to 30, 6 cases.

Netherlands: Rotterdam, March 23 to 30, 9 cases, 3 deaths.

Russia: Batoum, March 19 to 26, 6 cases, three deaths; Moscow, March 9 to 23, 6 cases, 1 death; Odessa, March 16 to 23, 1 death; Warsaw, March 9 to 16, 2 deaths.

Turkey: Constantinople, January 1 to 31, 134 deaths; February 1 to 28, 110 deaths.

West Indies: San Juan de Puerto Rico, January 9 to 30, 255 cases, 7 deaths; March 6 to April 3, 237 cases, 7 deaths.

HAVANA, CUBA, April 8, 1895.

Sir:—I have the honor of calling your attention to the mortuary reports recently forwarded to you, in which you will see that as far as the number of deaths from smallpox can indicate the progress of that disease, it has increased very considerably during the last twenty days.

It will be seen that during the week ending April 4 there were ten deaths from it, and during the week ending March 28 there were 12, while during the week previously there were none, and for several weeks before that there had been but one or two deaths a week. Nearly all of these deaths have occurred in the barrio of San Lazaro, a ward in which many poor people and cigar-makers live, and there the disease seems to be raging like a regular epidemic, for, for every death it is fair to calculate there must be from five to ten new cases. No official report of the number of cases of any disease is ever given here.

Your cablegram of the 4th inst. conveying instructions that whenever there should be an unusual increase of yellow fever to cable you, was promptly received and will be implicitly obeyed, but I am happy to inform you that up to date there has been no such increase, there having been but one death from it during the last week, with three new cases approximately. However, in all probability, in view of the large number of unacclimated troops which have arrived, are arriving and will arrive from Spain, there will be much more yellow fever here than usual some time during the coming summer.

Very respectfully, your obedient servant,  
D. M. BURGESS, U. S. Sanitary Inspector, M.-H. S.

## BOOK NOTICES.

**Publications du Progres Medical.** Paris. 14 Rue des Carmes. (Bibliotheque d'Education Speciale) Rapport et Memoires sur l'Education des enfants normaux et anormaux. Par E. O. SEGUIN. Preface par BOURNEVILLE. Volume 8 de XLVIII, 340 pages. Price 5 fr.

This book is part of a series of the "Educational Library" of the *Progrès Médical*. The publication of this volume, with a preface by the talented Bourneville, editor of the *Progrès Médical*, must be extremely gratifying to every American, as it is a collection of memoirs of the late Edward O. Seguin, of New York. Although Seguin was himself a Frenchman, Bourneville thinks it necessary to introduce him to the French people, which he does in an appreciative preface and fortifies his judgment of the man by a translation of the obsequies of Seguin at New York in 1880, in which Dr. Brockett, of Brooklyn, Dr. Wilbur, of Syracuse, Dr. George Brown, of Barre, Massachusetts, and Dr. Marion Sims took part.

The first part of the book is devoted to the education of the feeble-minded children, including the rooms in the asylum, the gardens, their plays, methods of instruction, etc. The second part is devoted to the education of deaf mutes and discusses the methods of Pereire, of the Anglo-Spanish school, the Abbe de l'Epee, and the Anglo-American school, as set forth in the writings of Wallace, Braidwood, Bell, Hirsch and others, known as visible speech or lip-reading. The third part is occupied with a discussion of the best means of education of idiots and feeble-minded. The institutions devoted to this benevolent object in all countries are passed in review. The fourth part is given to the discussion of popular education of children in various countries; the fourth chapter of this section is given to the metric system, and the author points out its great simplicity and general adaptability.

The volume concludes with Dr. Seguin's memoirs on idiocy, translated by Dr. Bourneville, and the whole constitutes a notable addition to the literature of the subject.

**Text-book of Diseases of the Kidneys and Urinary Organs.** By PROF. PAUL FÜRBRINGER; translated from the German, with Annotation by W. H. GILBERT, M.D., with a Commendatory Letter from SIR JAMES GRANGER STEWART. In two volumes. Volume I, octavo, pages 194. London: H. K. Lewis. 1895. Price, \$1.75.

Prof. Paul Fürbringer is Director of the Freiderichshall Hospital in Berlin, who has been known to the profession for many years as an able writer in various departments, particularly in connection with the kidneys and the urine. This volume opens with general remarks on albuminuria, hematuria, hemoglobinuria, renal casts, dropsy and uremia, and gives special and particular consideration to the circulatory disturbances of the kidneys, kidney disease in Asiatic cholera, renal affections during pregnancy, engorged kidney, hemorrhagic renal infarctions, inflammation of the kidneys, diffuse nephritis, acute diffuse nephritis, albuminuria in febrile diseases, chronic diffuse nephritis, contracted kidney, amyloid degeneration of the kidney, and infection of the kidneys leading to suppuration.

There is absolutely no padding in this book. It has been pruned, pared and freed from superfluities until from start to finish it is a solid compact mass of well-digested facts. To contemporaries, while not always agreeing with them in their conclusions, Fürbringer has been generous, and apparently has never omitted to mention the name of an individual connected with a theory or demonstration of any portion of the subject under consideration. In this respect the book is to be commended beyond any that has recently fallen under our observation. The deep knowledge displayed by the author, and his candor, should commend the work to all English-speaking people.

The translator and publisher have done their part well to give the book a handsome setting in its English dress. We shall look for the second volume of this work with increased interest. We observe with pleasure that the English translator has used the metric system of doses and measurements throughout the book.

**A Book of Detachable Diet Lists** for Albuminuria, Anemia and Debility, Constipation, Diabetes, Diarrhea, Dyspepsia, Fevers, Gout or Uric Acid Diathesis, Obesity, Tuberculosis, and a Sick-Room Dietary. Compiled by JEROME B. THOMAS, A. B., M.D. Philadelphia: W. B. Saunders; Chicago: A. C. McClurg & Co. 1895. Price, \$5.

This book will save the practitioner a great deal of work and be distinctly to his advantage, as there is every reason to believe that the general dietary is seldom carried out with the same care in private practice that is characteristic of it in hospitals, especially in military and naval service, where, as a rule, the diet is prescribed for the patient even before the prescription is written, and it is made possible with these lists to carry out the diet system in private practice with great ease. In addition to the list of articles given there is a collection of sick-room dietaries at the end of the book, which gives almost all of the forms of sick-room foods. These lists have been printed and bound in a book and perforated, so that they may be torn out when we have a patient to nurse as occasion may require. Ten lists are given, namely, those for patients with albuminuria, anemia and debility, diabetes, diarrhea, dyspepsia, fevers, gout or uric acid diathesis, obesity, tuberculosis, and a sick-room dietary.

**Medical Gynecology.** A Treatise on Diseases of Women from the Standpoint of the Physician. By ALEXANDER J. SKENE, M.D., Professor of Gynecology in Long Island College Hospital, Brooklyn, N. Y. With illustrations. 8vo, 529 pages. New York: D. Appleton & Co. 1895.

The volume is divided into three parts, of which Part I treats of development and growth, differentiation of sex, discusses heredity, environment and care in childhood, and mental and physical education. Part II treats of the char-

acteristics of sex and the relations between structure and function, the predisposition to peculiar diseases, and the etiology of diseases of women. The diseases of the child-bearing period are also carefully treated. In Part III the menopause and diseases after the climacteric are taken up. The observations of a well-trained observer like Dr. Skene can not fail to be interesting and instructive to the general practitioner, as well as specialist, and we predict that in the present movement against excessive operative treatment in gynecology, its advocates will turn naturally to the work of Dr. Skene as a safe one in which the lines between medical and surgical gynecology, although arbitrary, are clearly drawn.

**A Manual of the Modern Theory and Technique of Surgical Asepsis.** By CARL BECK, M.D. With 65 illustrations, and 12 full-page plates; 306 pages. Philadelphia: W. B. Saunders. 1895. Price, \$1.25.

This book is rather interesting, as it sets forth clearly and distinctly the modern practice of asepsis as distinguished from antiseptis. There are sixteen chapters, namely, I, of microbes; II, of asepsis; III, means of disinfection; IV, prophylactic disinfection; V, disinfection of instruments and dressings; VI, sterilization of catgut, silk, etc.; VII, sponges, drainage tubes and ligation tubes; VIII, an aseptic operating room; IX, aseptic wounds; X, infected wounds; XI, aseptic bone wound treatment; XII, renewal of dressing; XIII, technique of aseptic operation; XIV, aseptic injection; XV, anesthesia; XVI, asepsis of private practice. There have been several good books on this subject lately, notices of which have appeared in these columns, but the book under consideration is original in many respects. We commend it.

**Cod-liver Oil and Chemistry.** By F. PECKEL MÖLLER, Ph.D. London, 43 Snow Hill, E. C.; Christiania, Norway: Peter Möller. New York: W. H. Schieffelin & Co. Copenhagen: A. T. Møller & Co.; 508 pages. 1895.

This well-known firm of manufacturers have produced a book of great merit, not alone on account of the novel and interesting information in connection with the fishes and oil, but on account of the advanced chemistry it contains. One of the peculiar features of the chemic part of this work is the abandonment of the usual method of representing atomic parts in chemic formulæ and the introduction of a diagrammatic illustration. The book is an exceedingly interesting one, and notwithstanding its commercial origin is a distinct addition to medical literature.

**Transactions of the World's Columbian Dental Congress,** in two volumes. Edited for the General Executive Committee by A. W. HARLAN, A.M., M.D., D.D.S., assisted by LOUIS OTTOFY, D.D.S. Volumes I and II, paper, pages 1068. Chicago. 1894.

This handsome set of Transactions records the gathering of the greatest number of prominent practitioners of the dental art, and it is certainly a tribute to the fecundity and the great scope of medical science when one of its youngest departments can prepare and promulgate a scientific work of this character. Few realize the immense strides which the art of dentistry has made in the last few years, and although dentists in America were fond of pointing to this and the other one of their number as an example of the high scientific standard which American dentistry had attained, it was reserved for the French Commission, who visited America in 1887, to give to the dentists of the United States the proud position of the first rank in the dental art.<sup>1</sup> It was appropriate, then, that this first International Congress should be held in the United States, not only on account of the conceded preëminence of our dental practitioners, but on account of the recognition that has been extended to them as medical practitioners by the AMERICAN MEDICAL ASSOCIATION. Many languages were spoken at

<sup>1</sup> Kuhn: *L'Art Dentaire des Etats Unis*, Paris, 1888.

this Congress, which have been reduced in the Transactions to four, namely, French, German, Spanish and English. The suggestion was made in the closing of this Congress that, owing to the great success of the present one, future dental congresses should be held on each occasion of the holding of an International Exposition. This may be said to be the second Congress of this character, the first having been held in Paris in 1889.

The papers read in the various sections, along with the discussions, are printed in these volumes, and the work reflects great credit on the editors and the publication committee.

**King's College Hospital Reports**; being the Annual Report of King's College Hospital in the Medical Department of King's College. Edited by NESTOR TIRARD, M.D., F.R.C.P., W. WATSON CHEYNE, F.R.C.S., JOHN PHILIPS, M.A., M.D., F.R.C.P., W. D. HALLIBURTON, M.D., F.R.S. Vol. i. May 1, 1893, to Sept. 30, 1894. Price \$1.25; to non-subscribers, 7s. 6p. London: Adlard & Son. 1895.

It will be seen that this is the first volume of the reports of King's College Hospital and its Medical School. The volume opens with an historical sketch of the college and hospital by John Curnow, M.D., after which are articles as follows: Curable Stage of some Incurable Maladies, by Lionel S. Beale; Abstraction of Blood Clinically Considered, by Oliver B. Duffin; A Case of Functional Albuminuria, by Nestor Tirard; Psychology of Medicine in Relation to the Medical Practitioner, by Ernest W. White; Sneezing, by G. McDonald; On the Principle of Selection as Applied to the Administration of Anesthetics, by J. Frederick W. Silk; On Artificial Maturation of Immature Senile Cataract by Trituration, by Malcolm M. McHardy; On Some Cases of Pelvic Suppuration in the Female, by John Philips; Treatment of Gonorrhea and Gleet by Means of the Urethroscope, by F. Burghhard; Bursitis, by George Lenthal Cheate; The Value of the Discoveries of Sir Charles Bell, by William A. Turner; after which follow a classified summary of medical cases admitted during the year, notes of medical cases, tables of surgical cases, reports of fatal cases, reports of cases of interest, reports of various departments, the museum, the medical society of the College, report from volunteers, athletic records, and old students' dinner.

The illustrations in this book are all good, and some of them excellent. It is evident from a perusal of the papers that the work at King's College does not lag behind that of the other large hospitals of London.

**Report of the Massachusetts State Board of Health upon the Metropolitan Water Supply**, February, 1895. Boston: Wright & Potter Printing Co. 1895.

The State Board of Health of Massachusetts, under legislative act of 1893, was authorized and directed to investigate, consider and report upon the question of water supply for the city of Boston and its suburbs within a radius of ten miles from the State House, and for such other cities and towns as in its opinion should be included in connection therewith. This exhaustive report has been made in accordance with the law, and it affords an example which should be taken as a model for similar investigations in other portions of the United States. We have elsewhere referred to this report. (See page 293.)

**Manual of General Medicinal Technology, Including Prescription Writing**. By EDWARD CURTIS, A.M., M.D., Emeritus Professor of Materia Medica and Therapeutics, College of Physicians and Surgeons, Medical Department of Columbia College, in the City of New York. Third Edition, conforming to the U. S. Pharmacopœia of 1890. Pocket size (Wood's Pocket Manual Series), 245 pages. Price, \$1.

This little manual, small enough to carry in the pocket, has reached its third edition, which we are informed was made necessary by the changes in the Pharmacopœia of 1890. It is an excellent book and will be found useful for reference.

In our opinion, however, the author devotes too much space to the old apothecaries' system, which, since the adoption of the metric system in the new Pharmacopœia, has become practically obsolete.

**Ninth Annual Report of the State Board of Health and Vital Statistics of the Commonwealth of Pennsylvania**. By CLARENCE M. BUSCH; 833 pages. 1894.

This book includes the report of the Secretary, Dr. Benjamin Lee; report and analysis of water samples; reports of epidemics; quarantine; disinfectants, and of the water supplies in various parts of the State. There are few boards that work more harmoniously with municipal boards than the State Board of Health of Pennsylvania, and in consequence of this harmony they have been able to accomplish a great deal. The volume under consideration deserves to rank among the best of its predecessors.

**Report of the Commissioner of Education for the Year 1891-92**. Vols. I and II, containing Parts I, II, III. 1294 pages. Washington: Government Printing Office. 1894.

The report of the Commissioner of Education is of more than usual interest, and shows in a marked degree the great advances that have taken place in the evolution of the Bureau, which from its humble beginning in 1870, has now the reports on the school systems and university methods of all countries of Europe, comprised in these volumes. All those interested in education, either in a special department or generally, will do well to write for the report.

**The Evolution of the Diseases of Women**. By W. BALLS-HEADLEY, M.A., M.D. (Cantab) F.R.C.P. (London); 375 pages. London: Smith, Elder & Co.; Melbourne and Sydney: George Robertson & Co. 1894.

This book is intended by the author to be a "Contribution to the Study of the Natural History of Disease." The author's treatment seems sound, even if his pathology is a little hazy at times. The work is well illustrated and handsomely printed.

**Index of Medicine**. A Manual for the Use of Senior Students and Others. By SEYMOUR TAYLOR, M.D.; 794 pages. Philadelphia: Lea Brothers & Co. 1894.

This book contains in compact form the essentials of medicine, a short chapter on general pathology and general medicine, specific infectious diseases and specific fever, then the diseases of the different regions are taken up. It is an extremely convenient book for ready reference.

**The International Medical Annual and Practitioners' Index**. A Work of Reference for Medical Practitioners. Thirteenth Year Annual, 648 pages; New York: E. B. Treat, 5 Cooper Union. Chicago: 199 Clark Street. 1895.

This well-known annual contains the usual amount of new matter, as well as improvements and changes of the year. Its scope includes the entire range of medicine and surgery and the compilers are experienced literary workers.

**The Treatment of Wounds, Ulcers and Abscesses**. By W. WATSON CHEYNE, M.B. Ed., F.R.S., F.R.C.S.; 197 pages. Philadelphia: Lea Bros. & Co. 1895.

The author has been long known as one of the advanced men who practice asepsis in surgical work. This little work will be useful in furnishing the medical world with the careful style and technique of a master in surgery. Every surgeon should add this to his library.

**Transactions of the American Pediatric Society**. Sixth Session, held at Washington, D. C., May 29, 30, 31, and June 1, 1894. Edited by DILLON BROWN, M.D., New York. Vol. vi, paper. Reprinted from the *Archives of Pediatrics*. 1894.

These transactions comprise the reports read at the last meeting, held in Washington, 1894. There are eulogies of Drs. Keating and Earle by Dr. Forchheimer, of Cincinnati, and many interesting papers.

**The Year-Book of Treatment—1895**. Philadelphia: Lea Bros. & Co. 1895.

In this year-book we have one of the most compact of the several manuals that have been presented for consideration, inasmuch as it is very much condensed and very carefully edited. Those desirous of securing in condensed form a summary of the newer systems of treatment brought out during the year will do well to secure this volume.

## NECROLOGY.

**BERNHARD GRUNHUT, M.D.**, who was formerly of New York City, is alleged to have lost his life on or about August 22, of last year, when coming to this country on the steamer *Bothnia*. His estate, valued at \$150,000, has been the subject of a vast amount of litigation. Two days before he sailed he made a will leaving \$25,000 to his wife and the greater part of his estate, amounting to about \$100,000, to the Mount Sinai Hospital, and the Hebrew Benevolent Society of New York. There was also \$25,000 left to an unborn child, which amount was to revert to the residuary estate, should the child die before it was 21 years old. A child was born after the doctor's disappearance from the *Bothnia*, which lived a few hours. The contestants, a brother and a sister of the testator, endeavored to show that the Doctor was insane at the time of his marriage, and therefore, mentally incapable of entering into such a contract. Counsel for the contestants claimed that if the surrogate held that he had no jurisdiction, all that he could do was to permit them to withdraw. On this point the surrogate announced that he would reserve his decision. The will was then admitted to probate and the pending issue closed in the surrogate's court. The remainder of the estate is divided among a number of small legatees. Had the case been continued some interesting expert testimony on insanity would have been given. The defense had subpoenaed Dr. G. Alder Bloomer, Superintendent of the State Asylum for the Insane at Utica, and Drs. Jacobi, Dana and Spitzka, of New York, were among the medical witnesses who were expecting to be called to testify.

**JOHN W. COLES, M.D.**, retired surgeon of the United States Navy, died at his home in Philadelphia, April 6, in the fifty-seventh year of his age. Dr. Coles was born in New Jersey, on August 14, 1838. Soon after beginning the practice of medicine in May, 1863, he was appointed Acting Assistant Surgeon in the United States Navy from this State, and served in that capacity on the United States Ss. *North Carolina*. On June 25, 1863, he was made Assistant Surgeon, and was subsequently on duty on the United States Ss. *Paul Jones*, of the South Atlantic Blockading Squadron; at the Naval Battery, Morris Island, S. C.; United States ironclad, *Catskill*, of the South Atlantic Blockading Squadron; United States Ss. *Pontiac*; at the Naval Hospital, New York; and on the *Bienville*, West Indies. On January 14, 1867, he was promoted to Passed Assistant Surgeon, serving at the Naval Academy, on the *Lancaster* at Norfolk, Va.; on the *Ashuelot* in the Asiatic fleet. He also did special service on the United States Ss. *Minnesota* from May 7, 1869, and on July 3, 1868, was transferred to the Naval Hospital in this city. He was promoted to Surgeon in October, 1873, returning to duty at the Philadelphia Naval Hospital. He was assigned to the Naval Hospital at Yokohama, Japan, in April, 1875, and on returning to this country in 1878 was detailed on the Medical Examining Board and the National Board of Health at Washington. His last service was in this city at the Naval Hospital and as a member of the Medical Examining Board. He was placed on the retired list Feb. 6, 1885.

**GEORGE W. BATES, M.D.**, died at the residence of his father in Louisville on April 4, of pneumonia. Dr. Bates was born in Fairmount, Ky., about twelve miles from Louisville, Feb. 22, 1847. He received his education at Cecelian College, where he graduated in 1869. After this he taught school for several years in Carlisle, Ind., beginning the study of medicine at the Hospital College of Medicine in 1876, where he graduated Feb. 26, 1878. As a result of a competitive examination he received the appointment of interne at the Louisville City Hospital and served one year. He was associated for one year upon the beginning of his practice, with Dr. Willis. He has practiced continually since that date in Louisville. He had a chill at the funeral of his father whom he had attended during his illness from pneumonia, and died himself of pneumonia one week later. He was a widower but left no children.

**SWAYNE WICKERSHAM, M.D.**, Chicago, April 16. Dr. Wickersham was one of the oldest practitioners in Chicago. He was Commissioner of Health under Mayor Cregier. For some time his health had been gradually failing. Dr. Wickersham was a Quaker. He was born in the early 30's in

Pennsylvania and came to Chicago forty years ago. He was a member of the Cook County, State and American Medical Associations. He was unmarried and leaves a considerable estate. The remains will be taken to the home of his sister at Kennett, Pa., in accordance with his last wish.

**B. G. MERRY, M.D.**, of Stillwater, Minn., March 27, aged 62.—**J. H. Fuller, M.D.**, of Chattanooga, Tenn., April 2.—**James Kennedy, M.D.**, of San Antonio, Texas, March 30.—**J. B. Morgan, M.D.**, of Joplin, Mo., March 30, aged 72.—**Peter J. Dwyer, M.D.**, of St. Paul, Minn., March 30, aged 55.—**Horace Babcock, M.D.**, of Las Vegas, N. M., March 25.—**Thomas Wheat, M.D.**, of Manchester, N. H., March 25, aged 74.—**G. W. Cusick, M.D.**, of Tualatin, Ore., April 3, aged 54.—**Albert G. Anthony, M.D.**, of Oakland, Cal., April 3, aged 50.—**Carl Hoffman, M.D.**, of Baltimore, Md., April 8.—**H. C. Baker, M.D.**, of Kansas City, Mo., April 8, aged 50.—**George Gaston Brewer, M.D.**, of Baltimore, April 8, aged 59.—**B. H. Harris, M.D.**, of Groveland, Ill., April 6.—**L. C. French, M.D.**, of Hudson, Mich., April 12.—**J. T. Ball, M.D.**, of Rushville, Ill., April 4, aged 69.—**L. D. G. Gifford, M.D.**, of Watertown, N. Y., April 8, aged 38.—**A. H. Cochran, M.D.**, of San José, Cal., April 4, aged 64.—**C. D. O'Brien, M.D.**, of Ackley, Iowa, April 4.—**L. M. Tidrick, of Winter-set, Fla.**, April 3.—**J. W. Gill, M.D.**, formerly of Louisville, but lately of Danville, Ky., died at the latter place after a brief illness, April 2, of pneumonia.

## MISCELLANY.

**Change of Address.**—Dr. V. L. Hurlbut to Wellington Hotel, Chicago. Dr. S. S. Adams, to 1 Dupont Circle, Washington.

**Billroth's Monument.**—This memorial will soon be placed in the court of honor of the University of Vienna. A monument to Skoda and Rokitsky has been also ordered by the Council of the Faculty.

**Rennion.**—It is proposed to have a reunion of the class of 1874 of the Jefferson Medical College, on the evening of May 10, in Philadelphia. Members of the class who have not received an announcement will please forward their names to E. E. Montgomery, 1715 Walnut St., Philadelphia.

**Another "Faith-Cure" Fatality.**—The coroner at Dayton, Ohio, has held Col. F. B. Mead and his wife to be responsible for the death of their 12-year-old daughter, who was by them permitted to be treated by "faith-cure" methods, while she was suffering from tubercular meningitis.

**Health Officer of Chicago.**—Concerning various rumors afloat, we sincerely hope that the intense desire of Mayor Swift for civil service reform will not induce him to appoint a hod carrier or hotel drummer as Health Commissioner. There is a prejudice in favor of having a physician and sanitarian in that office. Why not retain Doctor Reynolds?

**The Hot-Air Cradle.**—This is the name given, at one of the New York city charities, the Bowery Mission, to a hot-air chamber, the use of which is to kill the vermin that infest the clothing of a portion of their lodgers. When the tramp disrobes for the night, his garments can, if he so desires, be placed in a wire pocket or cradle, and suspended in a hot atmosphere that does such cleansing as may be accomplished by dry heat.

**Dr. T. M. Drown Chosen President of Lehigh University.**—The election of Thomas M. Drown, M.D., etc., to the Lehigh Presidency took place on the 4th inst. Dr. Drown is a graduate from the medical department of the University of Pennsylvania, class of 1862, at which his ruling passion strong in graduation showed itself in the subject of his thesis, namely, Urological Chemistry. Dr. Drown has formerly filled the professorship of chemistry at Lafayette College, later at the Boston Institute of Technology. He was until recently the chemist of the Massachusetts State Board of Health.

**Presentation to Professor Sir William Turner.**—The colleagues and former pupils of Sir William Turner, Professor of

Anatomy at the University of Edinburgh, united in presenting a portrait of himself, as a testimonial of their esteem, respect and appreciation of his unfaltering zeal in the cause of science, and his faithful services to the University of Edinburgh. The picture, painted by Sir George Reid, P.R.S.A., is of three-quarter size, and portrays Sir William Turner in a characteristic pose while lecturing. Sir James Russell conducted the presentation ceremony which took place in the lecture room April 3, and was the occasion of the gathering of representative academic and medical men of the city.

**Longevity of Physicians.**—Dr. Salzmann, of Essling, Germany, has made a study of all the available facts regarding the above subject, to be found in the records of his country, going as far back as to the sixteenth century. In that century the life period of the medical man was 36.5 years; in the seventeenth 45.8; in the eighteenth 49.8, and in the current century 56.7. The gradual growth of preventive medicine, and especially those measures that have reduced typhus fever and smallpox, has tended to bring about the increased life rate.

**An English Colony for Epileptics.**—The *Echo* of London gives an abstract of the work done, during the first eight months, by the National Society for the Employment of Epileptics, which is essentially the record of success: "At Skippings Farm, Chalfont St. Peters, two or three epileptics were first of all placed, then two or three more, until, by the addition of units, never groups of persons, the number has grown to twenty; thus the family feeling has been preserved. The patients vary in age from 18 to 50, and 'most thoroughly repay the unremitting care and attention bestowed on them.' The work undertaken at present is, to a large extent, potato growing for market, vegetable gardening, carpentering, building, bootmaking and tailoring."

**Measurements of a Selected Venus.**—Out of five hundred applicants—more or less—for the position of a bronze Venus, in a New York show, one little woman filled the bill, whose measurements are said by her to be the following. She thus announces her statistics: "One artist says my figure is one of the best that he has ever seen, and I think myself the measurements show up very well. I am 5 feet 7 inches in height and weigh 155 pounds. My other measurements are: bust, 38 inches; waist, 26 inches; thigh, 22 inches; calf of leg, 15 inches; ankle, 9 inches; foot, 9 inches in length. My upper arm is 11½ inches, and my neck 13½ inches. Many women have figures superior to mine in certain points; but it is a most difficult thing to find a perfect, all-round figure."

**Another Survey of the Croton Watershed.—Filtration Necessary.**—Representatives of the New York city departments have again visited the Kensico district of the Croton system. Their informal reports show that much work is needed to furnish a desirable water from that region. The New York *Herald* insists that infiltration beds will need to be constructed before the good name of Croton will be re-established. The editor of that paper writes as follows: "The inspection was limited in its scope to the Kensico region. Kensico is reported 'the least safe of any of the supplies of the water service.' But further inspection may reveal other sources of dangerous contamination. It should not for a moment be forgotten by any New Yorker that the city's water supply never can be pure until some system of filtration is adopted. The most thorough purgation of the Croton basin that can possibly be made would at best be a poor make-shift for protecting citizens against polluted drinking water. No adequate protection is possible without filtration of all the water admitted to the main pipes. The sooner the public understands this and provides for real purification of the water supply the better it will be for the public health."

**Increased Losses of Life and Property by Lightning.**—In Germany, a paternal government controls in large measure the deforestation of the unsettled regions. The complaint has been made that this control was neither efficient nor wisely ordered, and that as a result the country was suffering un-

duly from lightning. The following report appears to confirm that view: "The director of the statistical bureau at Berlin has written a treatise on the increase of damage caused by lightning and its effects on the human body. Among the causes he assigns for increased destructiveness are the extended use of electricity, the changed character of the earth's surface through drainage, denudation of timber, etc., and the constantly increasing use of coal, by which impurities are introduced into the air. In Bavaria the annual average of fires caused by lightning was 52 for the period of 1844-1865, while for 1866-1879 it was 103, and for 1880-1882, 132.

**The Length of the Lower Limbs; Abraham Lincoln's Definition.**—There is an elaborate symposium in the *Independent*, having for its topic the life and death of President Lincoln. Among the anecdotes related of him is the following, which will be new to the majority of our readers: On one occasion it is said that some of Mr. Lincoln's friends were talking about him and Stephen A. Douglas. The conversation led to the physical proportions of the respective men and an argument arose as to the proper length of a man's leg. During the discussion Mr. Lincoln came in and quietly seated himself, and it was agreed that the question should be referred to him for settlement. They told him what they had been talking about and asked him what, in his opinion, was the proper length of a man's legs. "Well," said he, reflectively, "I should think that they ought to be long enough to reach from his body to the ground."

**Crew Space.**—The Bureau of Navigation calls attention to a recent act which went into effect April 1, 1895: "Every place appropriated to the crew of a vessel must contain not less than 72 cubic feet and not less than 12 superficial feet, measured on floor or deck of that place for each seaman or apprentice lodged therein. Such place shall be adequately ventilated, properly lighted, drained and protected from weather and sea, and as far as practicable properly shut off and protected from effluvia of cargo and bilge water; and failure . . . shall subject owner to penalty of \$500."

Such place must be kept free from goods or stores under penalty for non-compliance.

"Sec. 3. . . . provisions of this act requiring a crew space of 72 cubic feet per man shall apply only to vessels the construction of which shall be begun after June 30, 1895."

### College Commencements.

THE ATLANTA, GA., MEDICAL COLLEGE.—April 2, one hundred and thirty-five graduates.—Bellevue Medical College, N. Y., March 25, eighty-nine graduates.—Tennessee Medical College of Knoxville, March 26, fifteen graduates.—St. Louis College of Physicians and Surgeons March 26, forty-nine graduates.—The Omaha, Neb., Medical College, April 3, twenty-four graduates.—The Southern Medical College at Atlanta, Ga., April 3, sixteen graduates. Total, 328 graduates.

### Hospital Notes.

THE regular monthly meeting of the board of managers of the New York State Hospital was held in Utica, April 10. The report of the Superintendent showed that there were 1,028 patients in the hospital. The twenty-fourth annual report of the Mercy Hospital at Davenport, Iowa, shows 164 inmates. Nearly \$200,000 have been expended on the grounds.—Plans are being prepared for the purpose of building a floating hospital at Providence, R. I. It is intended for use in contagious diseases.—The St. Vincent's Hospital Society of Toledo, Ohio, was organized April 7. This society is formed for charitable purposes, and will aid the St. Vincent's Hospital and Orphan Asylum.—The new cottage hospital for the insane at Independence, Iowa, was formally opened April 16.

### Society Notes.

THE annual meeting of the District Medical Society of Northwest Missouri was held at St. Joseph, Mo., April 11.

The following officers were elected for the ensuing year: President, D. D. Bryant, of Savannah; Vice-President, W. W. Carter, of Wathena; Secretary and Treasurer, B. M. Berry, of Chicopee Falls; Secretary and Treasurer, J. M. Townsend, of St. Joseph. The next meeting of this society will be held in July.—A quarterly meeting of the Iowa and Illinois District Medical Association was held in Davenport, Iowa, April 11.—The Eastern Hampden Medical Association held its fifteenth annual meeting in Springfield, Mass., April 4. The following officers were elected: President, George T. Ballard, of Hampden; Vice-President, L. M. Berry, of Chicopee Falls; Secretary and Treasurer, J. M. Hannum of Ludlow.—The Snyder County Medical Society held a regular meeting at Selina Grove, Pa., April 4. The following officers were elected: President, A. M. Smith; Vice-President, J. F. Kanawell; Secretary and Treasurer, J. O. Wagner.—The annual meeting of the Cuyahoga County Medical Society was held in Cleveland, Ohio, April 4. The following officers were elected: President, H. E. Haldeman; Vice-President, H. C. Eyeman; Second Vice-President, W. C. Weber; Secretary, B. F. Oswald.—A regular meeting of the Cleveland Medical Society was held April 12.—The Lehigh County Medical Society met in Allentown, Pa., April 10. Resolutions were passed relative to the prevention of blindness.—The annual meeting of the Oneida County Medical Society was held in Rome, N. Y., April 9. The following officers were elected for the ensuing year: President, Charles E. Smith, Whitesboro; Vice-President, Charles G. Ward, Utica; Secretary, David Eynon, Utica; Treasurer, H. G. Jones, Utica.—The Twin City Medical Society held a meeting in Kansas City, Mo., April 9. The following officers were elected: President, E. H. Thraillkill; First Vice-President, A. R. Greenlee; Second Vice-President, L. A. Schaefer; Secretary J. N. Jackson.—A regular monthly meeting of the Los Angeles Medical Society was held April 5.

#### Philadelphia Notes.

**OBSTETRICAL SOCIETY.**—The April meeting of the Obstetrical Society had a discussion on the subject of uterine fibroids especially the treatment of this condition when complicating pregnancy. Dr. Anna M. Fullerton of the Woman's Hospital read a paper and presented specimens and photographs, which form a valuable contribution to the subject. Dr. Geo. E. Shoemaker reported a case of hysterectomy by ligation for fibroma. He also presented a very interesting specimen showing anastomosis of the small intestine by the Murphy button, the operation having been performed eleven months before death by Dr. J. B. Murphy when on a visit to this city in September, 1893. It was done originally to close a fecal fistula following strangulated hernia, but the operation was not successful. Another attempt nine months later was made by Dr. Holmes, to close the fistula by resection and button anastomosis but death resulted from exhaustion.

#### Louisville Notes.

**LONG.**—Dr. John L. Long has been appointed expert to the State Board of Health, to be sent any place in the State where smallpox is suspected to exist, and there is no doubt as to the diagnosis. The choice is an excellent one and the appointment one of importance, as there has been considerable conflict between local physicians in different parts of the State and the health authorities, when a diagnosis was in doubt. Dr. Long was for several years Superintendent of the Louisville City Hospital, but has again entered the practice of medicine, limiting his practice to genito-urinary and skin diseases.

**DEATH REPORT.**—During the past week there was a total of eighty-seven deaths; of these twenty-six were due to pneumonia, fourteen to consumption, four to organic heart disease. There were eight still-births: Forty-two were single, thirty-eight married, sixty-eight white, nineteen colored, three died at the City Hospital. The percentage of deaths from pneumonia still continues enormous.

#### Washington Notes.

**MEDICAL SOCIETY OF THE DISTRICT.**—At the regular meeting of the society held on the 3d inst., the essay of the evening was read by Dr. Anita Newcomb McGee, subject, "Esoteric Medical History" of the Oneida Community. Twenty-five new members were elected to membership.

At the meeting of the society held on the 10th inst., Dr. Andrew H. Smith, of New York, the guest of the society, read an essay entitled "Some Points in the Physical Examination of the Chest." The discussion was opened by Dr. W. W. Johnston, and continued by Drs. Prentiss, Stowell, Adams and others. Dr. H. L. E. Johnson reported nine successful cases of laparotomy and presented specimens. Dr. G. L. Magruder reported a case of cancer of the stomach.

**THE WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.**—The two hundred and twenty-sixth meeting of the society was held April 5. Dr. T. C. Smith read the paper of the evening, entitled, "A Case of Hypertrophy of the Cervix Uteri, complicating Pregnancy and Labor." The hypertrophied cervix was amputated post-partum and the woman restored to health. The cervix was six inches long and protruded from the vagina. An instructing discussion followed. Dr. H. L. E. Johnson presented an interesting specimen of ovarian cyst removed by himself on the 22d ult. The fimbriated extremity was closed, largely distended with fluid, intimately adherent to the cyst wall and the two cavities separated by a very thin septum. It was a tubo-ovarian cyst in transition stage.

**DR. S. C. BUSEY.**—The profession will be pleased to learn that Dr. Busey, who is confined to bed with a fracture of the right hip, is resting comfortably and is expected to make a speedy recovery.

**DR. J. FORD THOMPSON,** who has been dangerously ill from a septic injury is considered out of danger.

**HEALTH OF THE DISTRICT.**—The report of the Health Officer for the week ended April 9 is as follows: Number of deaths (still-births not included), white 55, colored 49, total 104.

**FIRE ESCAPES FOR HOSPITALS.**—The Commissioners are requiring all hospitals in the District to comply with the law of March 2 by providing suitable fire escapes, stand pipes, red lights, etc.

## THE PUBLIC SERVICES.

### NOMENCLATURE AND CLASSIFICATION OF DISEASES.

Statistical nomenclature and classification of diseases and injuries; Medical Department of the Navy of the United States—in operation Jan. 1, 1895.

#### CLASS I.—PARASITES AND PARASITIC DISEASES.

Actinomycosis.	Oxyuris vermicularis.	Tenia.
Ascaris lumbricoides.	Podiculus.	Tinea favosa.
Echinococcus.	Pityriasis.	Tinea trichophytina.
Filaria medinensis.	Pulex penetrans.	Trichinosis.
Filaria sanguinis.	Scabies.	Other dis's of this class.

#### CLASS II.—GENERAL INFECTIOUS DISEASES.

(Non-venereal.)

Cachexia malarialis.	Gangrena nosocomialis.	Sepsicemia.
Catarrhus epidemicus.	Cholera.	Tetanus.
Cholera morbus.	Morbilli.	Tuberculosis miliaris acuta.
Dengul.	Neuritis endemica.	Tuberculosis pneumonica acuta.
Diphtheria.	Paralysis ascendens acuta.	Tuberculosis pneumonica chronica.
Dysenteria acuta.	Parotitis epidemica.	Tuberculosis of other parts.
Dysenteria chronica.	Pertussis.	Typhus.
Erysipelas.	Pyemia.	Vaccina.
Febris cerebro-spinalis.	Rabies.	Varicella.
Febris enterica.	Rheumatismus articularis acutus.	Varola.
Febris flava.	Rheumatismus articularis chronicus.	Other diseases of this class.
Febris intermittens.	Rubella.	
Febris pneumonica.	Scarlatina.	
Febris recurrens.		
Febris remittens.		

#### CLASS III.—CONSTITUTIONAL DISORDERS OF NUTRITION.

Anemia.	Hemophilia.	Purpura hemorrhagica.
Debilitas senilis.	Leucocythemia.	Purpura simplex.
Diabetes insipidus.	Lithemia.	Scorbutus.
Diabetes mellitus.	Pseudoleucocythemia.	Other dis's of this class.

#### CLASS IV.—DISEASES OF THE NERVOUS SYSTEM.

Apoplexia.	Irratio spinalis.	Paraplegia.
Aphasia.	Mania.	Prostatio thermica.
Atrophia muscularis progressiva.	Melancholia.	Sciatica.
Cephalalgia.	Meningitis.	Sclerosis lateralis amyotrophica.
Chorea.	Monoplegia.	Sclerosis lateralis spastica.
Dementia.	Myelitis.	Sclerosis multiplex.
Encephalitis.	Nausea marina.	Sclerosis spinalis posterior.
Epilepsia.	Neuralgia.	Syncope.
Febris continua simplex.	Neurasthenia.	Torticollis spasmodica.
Febris ephemera.	Neuritis.	Vertigo.
Febris thermica.	Neuritis multiplex.	Other diseases of this class.
Hemicrania.	Neurosis hysteroides.	
Hemiplegia.	Paralysis agitans.	
Iusomnia.	Paralysis glosso-laryngealis.	
	Parauoia.	

#### CLASS V.—DISEASES OF THE VISUAL APPARATUS.

Achromatopsia.	Corneæ ulcus.	Myopia.
Amaurosis.	Dacryocystitis.	Neuritis optica.
Amblyopia.	Entropium.	Obstruction lacrymalis.
Asthenopia.	Entropium.	Panophthalmitis.

Astigmatismus.	Glaucoma.	Pterygium.
Blepharitis.	Hordeolus.	Retinitis.
Cataracta.	Hypermetropia.	Scleroditis.
Chalazion.	Iritis.	Synechia.
Choroiditis.	Keratitis.	Trachoma.
Conjunctivitis.	Leucoma.	Other dis's of this class.

## CLASS VI.—DISEASES OF THE AUDITORY APPARATUS.

Myringitis.	Otitis externa.	Surditas.
Otalgia.	Otitis media.	Other dis's of this class.

## CLASS VII.—DISEASES OF THE OLFACTORY APPARATUS.

Antri abscessus.	Rhinitis acuta.	Other diseases of this class.
Catarrhus estivus.	Rhinitis chronica.	

## CLASS VIII.—DISEASES OF THE NUTRITIVE APPARATUS.

## SUBSIDIARY CLASS I.—DISEASES OF THE DIGESTIVE APPARATUS.

Adenitis salivosa.	Diarrhea simplex.	Obstructio intestinalis.
Ani-prolapsio.	Dyspepsia nervosa.	Odontalgia.
Ani-rhagades.	Fistula in ano.	Odontolithus.
Appendicitis.	Gastralgia.	Esophagostenosis.
Catarrhus gastricus acutus.	Glossitis.	Parulis.
Catarrhus gastricus chronicus.	Hematemesis.	Peridontitis.
Catarrhus intestinalis acutus.	Hemorrhoids.	Periproctitis.
Catarrhus intestinalis chronicus.	Hepatitis congestio.	Peritonitis.
Cholelithiasis.	Hepatitis acuta.	Pharyngitis.
Colica.	Hepatitis chronica.	Stomatitis.
Constipatio.	Hepatitis suppurativa.	Tonsillitis.
Dentis caries.	Hypertrophia tonsillarum.	Typhilitis.
	Icterus.	Ulcus gastricum.
	Intestini recti strictura.	Uvula descendens.
		Other diseases of this class.

## SUBSIDIARY CLASS 2.—DISEASES OF THE CIRCULATORY APPARATUS.

A—Blood Vessels.		
Aneurysma.	Cordis palpitatio.	Myocarditis.
Angina pectoris.	Cordis valvularum morbus.	Pericarditis.
Arteriosclerosis.		Phlebitis.
Cordis dilatatio.	Embolismus.	Thrombosis.
Cordis hypertrophia.	Endocarditis.	Varix.
B—LYMPHATICS.		
Bronchocele.	Lymphangitis.	Other diseases of this class.
Lymphadenitis.	Splenypertrophia.	

## SUBSIDIARY CLASS 3.—DISEASES OF THE RESPIRATORY APPARATUS.

Asthma.	Emphysema pulmonalis.	Pleuritis acuta.
Bronchopneumonitis.		Pleuritis chronica.
Bronchitis acuta.	Hemoptysis.	Pleuritis purulenta.
Bronchitis chronica.	Laryngitis acuta.	Pneumothorax.
Catarrhus bronchialis.	Laryngitis chronica.	Other dis's of this class.
	Edema pulmonalis.	

## CLASS IX.—DISEASES OF THE MOTORY APPARATUS.

Ankylosis.	Gangrena.	Periostitis.
Arthritis.	Myalgia acuta.	Synovitis.
Arthritis deformans.	Myalgia chronica.	Thecitis.
Bursitis.	Neerosis.	Other diseases of this class.
Caries.	Ostitis.	
Contractura.	Osteomyelitis.	

## CLASS X.—DISEASES OF THE CUTANEOUS APPARATUS.

Abscessus.	Furunculus.	Pityriasis.
Acne.	Herpes simplex.	Prurigo.
Carbunculus.	Herpes zoster.	Psoriasis.
Cellulitis.	Impetigo.	Ulcus.
Clavus.	Lichen.	Unguis involutus.
Cutis fissurae.	Oocythia.	Urticaria.
Ecthyma.	Paronychia.	Verruca.
Eczema.	Pemphigus.	Other diseases of this class.
Erythema.	Pernio.	

## CLASS XI.—VENEREAL DISEASES AND DISEASES OF THE GENITO-URINARY APPARATUS.

Adenitis inguinalis (venereal).	Hydrocele.	Spermatorrhea.
Arthritis gonorrhoea.	Nephritis acuta.	Syphilis consecutiva.
Balanitis.	Nephritis chronica.	Syphilis primitiva.
Calculus.	Nephrolithiasis.	Urethra strictura.
Chaneroid.	Ophthalmia gonorrhoea.	Urethritis simplex.
Cystitis.	Orchitis.	Urina suppressa.
Euuresis.	Paraphimosis.	Urina retentio.
Epididymitis.	Perinephritis.	Varicocele.
Fistula urinaria.	Phimosis.	Verruca acuminata.
Gonorrhea.	Prostatitis.	Other diseases of this class.
Hematuria.	Pyelitis.	

## CLASS XII.—CYSTS AND NEW GROWTHS.

Adenoma.	Epithelioma.	Neuroma.
Angioma.	Fibroma.	Osteoma.
Carcinoma.	Glioma.	Sarcoma.
Chondroma.	Lipoma.	Other diseases of this class.
Cystis.	Myxoma.	

## CLASS XIII.—INJURIES.

Abrasio.	Fractura.	Sole excoctus.
Ambustio ex calore.	Furunculus ictus.	Stemma.
Ambustio ex frigore.	Hernia.	Virium defectio.
Asphyxia.	Ictus electricus.	Vulnus contusum.
Asphyxia ex submersione.	Luxatio.	Vulnus incisum.
Concussio.	Membrana tympani ruptio.	Vulnus laceratum.
Contusio.	Membranes clades.	Vulnus punctum.
Deformitas.	Musculi ruptio.	Vulnus scoploptum.
Fames.	Visceris ruptio.	Other diseases of this class.
	Sitis.	

## CLASS XIV.—EXTRANEUS BODIES.

## Corpus extraneum.

## CLASS XV.—POISONS.

Alcoholismus.	Venenum irritans.	Vulnus venenatum.
Dermatitis venenata.	Venenum neuroticum.	Other dis's of this class.

The form must not be altered by erasure nor interlineation, and the names of the diseases specified shall be employed in classification and diagnosis whenever practicable. Diseases not included in this table shall be returned as "Other diseases of this class," in the class to which

they belong, and, observing the same classification, shall be specified alphabetically in the "Supplementary Table," page 12, care being taken to avoid terms synonymous with those already employed.

No symptom shall be considered as the diagnosis of any case when it is practicable to classify it under the disease which is its cause.

Each genus shall include its varieties unless the variety appear in the table, e.g., melancholia includes nostalgia, hypochondriasis, lypothymia, etc.; neuralgia includes trigeminal, occipital, cervico-brachial, and intercostal neuralgias, neuralgias of the joints, genitals, rectum, etc., but acata, gastralgia, and certain others occupy places of their own; amblyopia includes hemeralopia, nyctalopia, etc.; asthenopia includes asthenopia muscularis, etc.; meningitis includes hemorrhagic pachymeningitis, leptomenigitis, etc.; alcoholismus includes delirium tremens, ebriosis, etc.; myalgia includes omalgia, lumbago, rheumatic torticolis, pleurodynia, etc.

In making a diagnosis, preference shall be given to the primary disease except where the secondary disease, specified in the nomenclature, is the main or only cause of admission to the sick list or retention thereon, or overshadows the primary disease, e.g., adenitis inguinalis, orchitis, or epididymitis may be the main cause of admission or the only cause of retention on the sick list though co-existing with gonorrhea; sclerositis spinalis posterior may overshadow syphilis consecutiva, or arthritis gonorrhoea, gonorrhea, etc.

## Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from April 6, 1895, to April 12, 1895.

Capt. REUBEN L. ROBERTSON, Asst. Surgeon, is granted leave of absence to and including July 3, 1895, on which date his resignation has been accepted by the President to take effect.

Capt. JAMES E. PILCHER, Asst. Surgeon, is granted leave of absence for two months, on surgeon's certificate of disability.

Capt. WILLIAM B. BANISTER, Asst. Surgeon, is relieved from duty at Ft. McIntosh, Texas, and ordered to Ft. Omaha, Neb., for duty.

First Lieut. FREDERICK P. REYNOLDS, Asst. Surgeon, is granted leave of absence for one month, to take effect upon his relief from duty at the U. S. Military Academy, West Point, N. Y.

The following named officers will report in person to Major CALVIN DEWITT, Surgeon, President of the examining board appointed to meet at Ft. Leavenworth, Kan., on Wednesday, May 1, 1895, at such time as they may be required by the board, for examination as to their fitness for promotion, and upon conclusion of their examinations, will return to their proper stations: First Lieut. THOMAS U. RAYMOND, Asst. Surgeon; First Lieut. HENRY D. SNYDER, Asst. Surgeon; First Lieut. ALLEN M. SMITH, Asst. Surgeon; First Lieut. JOSEPH T. CLARKE, Asst. Surgeon.

## Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending April 13, 1895.

P. A. Surgeon G. MCC. PICKRELL, detached from U. S. S. "Newark," and granted three months' leave.

Asst. Surgeon A. W. DUNBAR, detached from U. S. S. "Vermont," and ordered to the U. S. S. "Newark."

Asst. Surgeon HENRY LA MORTE, detached from U. S. S. "Newark," ordered home and two months' leave.

Asst. Surgeon C. P. BAGG, detached from U. S. N. Hospital, Mare Island, Cal., and to the U. S. S. "Monterey."

## LECTURES.

### LECTURES ON INTRACRANIAL SURGERY.

#### VI—BRAIN TUMOR AND ITS SURGICAL TREATMENT.

BY EMORY LANPHEAR, M.D., PH.D.

ST. LOUIS, MO.

Continuing the discussion of brain tumor and its surgical treatment, I will first speak of the

*Symptoms of Cerebellar Tumor.*—Tumor of the cerebellum may give rise to no characteristic symptoms whatever. Loomis has reported a case in which there was simply a low grade of fever; yet the post-mortem examination revealed a cerebellar tumor as large as an orange. Commonly, however, there are marked symptoms—sometimes so pronounced as to make localization absolutely certain: vomiting with occipital headache and general failure of health, without other discoverable cause, will almost certainly call attention to the proper region; besides, as the tumor grows, pressure symptoms arise. They are thus enumerated by Wood: "Encroachment on the medulla may lead to imperfect hemiplegia or even to great motor failure; or hypoglossal, or facial, or other local paralysis may result from the pressure exerted by the enlarged cerebellar hemisphere upon nerve trunks. If the trigeminus be involved a true anesthesia dolorosa may be produced; loss of power of swallowing may be a prominent symptom. On account of proximity to the sight centers, blindness from pressure is not an infrequent result of cerebellar tumors." When the lesion occupies the middle lobe of the cerebellum it causes peculiar disturbances of motion called cerebellar titubation. This was typically illustrated in a case that came under my observation in 1890:

Annie Buford, colored, 19 years of age, for many weeks presented these symptoms: occipital headache, vertigo, vomiting, tenderness over the right occipital region and cerebellar ataxia; reflexes normal; her general condition was excellent, but she became somewhat thin on account of persistent vomiting; late in the history, choked disc was prominent; cerebellar titubation was marked—she could only stand with feet widely separated, as when brought close together she would sway and fall to the floor unless caught, but closing the eyes did not cause any increase of the tendency to fall; in walking she could not turn quickly, and there was a constant inclination to fall to the right; but when lying on her back she had perfect control of the lower extremities. Tumor of the middle lobe of the cerebellum was diagnosed and operation urged. It was refused persistently. One day while washing dishes she suddenly fell to the floor unconscious and died in a few moments. The autopsy (by Dr. J. B. Jones and myself) confirmed the accuracy of the diagnosis; the tumor was nearly as large as a hen's egg and extended—at the time of death—to the fourth ventricle; so operation during the last few weeks of life would have proved fatal, though doubtless early extirpation might have been possible. Microscopic examination showed the growth to be tubercular in character.

The cerebellar titubation is ordinarily accompanied by giddiness. The attitude is that of a tabetic person; the feet held forward and well separated. When

they are brought together there is present a singular movement of flexion and extension in the feet, while the body begins to sway, and a fall to the floor follows unless some assistance is afforded. Sometimes these movements are in one direction, but more frequently they are irregular; often the patient can not turn suddenly, so the walk resembles that of a person intoxicated. Festination is rarely a symptom. When in bed the patient can use the legs as perfectly as ever. Nothnagel has clearly proved that this titubation invariably means disease of the middle lobe of the cerebellum. When the cerebellar peduncles are implicated, rotatory movements appear.

Rosenthal enumerates the diagnostic points of tumor of the cerebellar peduncles as headache, vertigo, disorders of the special senses, unsteady gait with tendency to fall upon the side, and partial rotation around the vertical axis.

#### DIAGNOSIS.

After a careful study of the symptoms of cerebral and cerebellar growths, as I have given them, there should be little difficulty in making a correct diagnosis. The only diseases with which brain tumor can be confounded are cerebral or cerebellar abscess, cerebral thrombosis, meningitis (chronic forms), lead poisoning, hysteria and parietic dementia. A chronic basilar meningitis is particularly misleading. The essential features of each of these diseases and the points of differential diagnosis may be found in any good work upon diseases of the nervous system. For deciding the location of the lesion, the symptoms already mentioned, coupled with the subjects to be considered later under the head of cerebral localization will suffice.

#### OPERATION.

It having been determined that the growth is so situated as to admit of excision, the steps to be followed are these: after proper preparation, a flap of scalp and periosteum at least three inches broad is turned back from the area to be opened. The trephine is applied and a button removed, or a small opening made with a gouge or chisel; this opening is enlarged until it is at least one and one-half by two inches, with cutting forceps, and the dura inspected while bleeding is being checked. The dura is opened by a flap slightly smaller than the hole in the bone, and the brain exposed and examined; especially by palpation, to decide as to the location of the tumor if not at once visible. When the situation of the growth has been exactly determined, operative procedures may be resumed.

The pia may be carefully raised with the vessels of the brain, the latter slipping out of the sulci without serious rupture in most localities. Then the tumor may be removed either with a very thin sharp knife, or curetted away with a Volkmann's spoon; in case of tubercle or other soft tumor the latter is prob-

ably the better method. Extreme care must be taken to remove all diseased tissue; which is particularly important of malignant neoplasms. Quite often the growth may be readily enucleated—shelled out from the surrounding brain substance, the fibers of which have been simply pushed asunder with no infiltration; in which instance the operation is comparatively simple. But when the normal tissues are intimately mixed with the diseased structures there is frequently great difficulty, and the surgeon is compelled to cut at considerable distance from the center of the tumor—if so, as much gray matter should be preserved as possible, the cut slanting inward around the mass to be removed.

When extirpation is completed, a roll of iodoform gauze, wrung from very hot water, is placed in the wound, with firm pressure, to control hemorrhage. By making pressure with these hot balls of gauze for about five minutes all capillary hemorrhage can be checked—a method of hemostasis much to be preferred to the Paquelin cautery which is sometimes used. It is sometimes necessary to ligate bleeding vessels too large to be controlled by heat and pressure, especially if the cut has extended down near to or into the lateral ventricle. If—as sometimes has happened in the past—it is found that the bleeding continues in spite of these efforts, there remains but the alternative of packing (as firmly as dared) with iodoform gauze.

As soon as bleeding has been checked the wound is irrigated with hot normal salt solution (temperature 110 degrees) and dried, a plenty of iodoform dusted in, the pia and vessels gently replaced and the dura sewed with fine catgut; with or without catgut drainage as may be indicated—without it by all means if possible. A few strands of catgut are laid to the dura and allowed to project through the scalp at the lower end of the incision. The scalp is finally closed with continuous catgut suture and the usual dressings applied.

If the Paquelin cautery is brought into use to control hemorrhage, the wound must be drained for some four or six days. When the wound has to be packed with iodoform gauze for hemostatic purposes the tampon must be removed with the utmost gentleness and under the most scrupulous antiseptic precautions at the end of thirty-six to forty-eight hours. After its removal the patient must be kept absolutely quiet for forty-eight hours longer or bleeding may be caused to return.<sup>1</sup>

When a cystic tumor is the variety found, the cyst should be extirpated entire if possible. The most extreme care is required in pushing away the fibers next to the tumor. If, in spite of all precaution, the cyst ruptures, the wound must be immediately and thoroughly irrigated and then the sac of the tumor carefully dissected out to prevent recurrence; this not being possible, it is best to gently curette the remaining cyst wall and insert a drainage tube, as very good results may be thus obtained.

All incisions in the white substance should be made parallel with the fibers of the corona radiata—that is practically perpendicular to the lateral ventricle—or as nearly so as practicable.

Exploratory puncture may be made in various

directions to ascertain the presence of any hard mass when no tumor can be made out by palpation. This is to be done with a fine needle. When the needle has been run into brain tissue no attempt must be made to change its position until it has been entirely withdrawn, as serious injury to associated fibers would otherwise result. The needle may be thrust in again and again without much harm if this precaution be observed—provided that the point is never allowed to come near the base of the brain nor the region of the pons and medulla.<sup>2</sup>

If absolutely necessary in order to complete the exploration, an incision may be made down to the suspicious point; this will be rarely called for and should never be done unless urgently demanded. The resulting cicatrix may, in certain regions, give rise to serious consequences.

If the tumor be found so extensive as to defy removal, the dura is to be closed over it with fine catgut stitches and the opening in the skull enlarged until it is fully two or two and a half inches by four or four and a half—to allow relief from the dangerous and agonizing intracranial pressure.

When the tumor is very vascular (as when in the meninges) it becomes necessary to surround it with a number of catgut ligatures before extirpating. The gut may be simply passed around the vessels, one by one, with a needle and tied; but when they are not superficial it becomes necessary to pass the sutures deeply into brain tissue with a large curved needle and tie *en masse*, with very little force; these sutures are repeated until the tumor has been entirely gone around, when the cutting can be done in the circle thus made with little hemorrhage except from the under surface—which can be checked after excision is finished.

The after treatment is the same as that of any other trephining and will be described in another lecture, when the general subject of head operations is under consideration.

#### CASES.

It has been my good fortune to operate upon eight cases of brain tumor—some of them of great interest on account of their rarity as well as the favorable results obtained. The first one I will mention is

*Angioma of the Meninges—Removal—Recovery.*—Roy L., of Independence, Kan., 12 years of age, was brought to me Nov. 29, 1892. The history showed inherited neurotic tendency; previous health good; was unusually intelligent during early life, but at the age of 3½ years began to have “night terrors,” and after a time epilepsy developed; for the last three years convulsions had been severe and frequent and his mental development very slow; spasms were much more frequent at night and were confined to the right side of the body for months and always began there, even after the culmination in general epilepsy.

Examination showed him in excellent physical condition; mental development limited; his language was fairly good, though sharp and quick, and very childish expressions only were employed. He had never been able to learn to read. His right side was far less developed than the left, and his motions were mostly of the left hand.

October 1, 1893, operated at All Saints' Hospital, Kansas City, assisted by Dr. T. B. Thrush and J. F. Binuie, opening the skull with a gouge and enlarging with cutting bone-forceps until a space two by four inches was cleared over the frontal and parietal regions. Upon cutting through the dura a tumor measuring about one and one-half inches across was found growing apparently in the meninges over the upper

<sup>1</sup> In an operation for epilepsy due to old depressed fracture, (case of Joseph A. Barton) I removed the packing from the wounded superior longitudinal sinus at the end of forty-eight hours. Some hours later, during the temporary absence of the nurse, the patient rolled out of bed and set up the hemorrhage with fatal results.

<sup>2</sup> The normal brain tissue is much softer than generally imagined, and unless the surgeon is thoroughly familiar with the natural consistency of the cerebral structures he should chloroform a dog, open its cranium and carefully practice this exploratory puncture, as well as cutting the brain before attempting operation.

If answered in the affirmative, a second question naturally follows: did the sarcoma begin its development soon after the injury? There are certain things about the history to lead us to infer that such was the case; *e. g.*, almost exactly two years after the accident he had a convulsion which left a paralysis of the left arm for some time. What was the cause of this epileptic paroxysm in a patient otherwise in perfect health and free from neurotic tendency? Was it an extradural (sub-cranial) hemorrhage, or was it an irritation due to the presence of the tumor already developing? We can only surmise as to the proper answer. Slowly growing spindle-celled sarcomata have been reported by a number of observers; Warren in his "Surgical Pathology" (page 718) speaking of sarcoma affecting the parietal bone and its periosteum mentions a sarcoma of the dura which persisted from 1846 to 1866 and says: "Other cases of slow growth of these tumors are recorded; one of twenty years, one of fifteen years, and several of four or five years duration." If we take it for granted that this growth began as late as the time of the first convulsion, May, 1887, a period of more than five years elapsed before it caused death.

The query then arises, Why did it not occasion serious trouble earlier in its history? The reply I have already given, in the assertion that the brain often shows a remarkable tolerance to slowly increasing growths, and that only when a tumor reaches a size sufficient to interfere with vision is its existence suspected. This patient knew there was something "wrong in his head," as he expressed it, for some time, but did not regard it as serious until his eyesight failed. He then sought the oculist, who immediately recognized the fearful seriousness of the case, explained that less than two months of life probably remained and advised removal as the only possible escape; unfortunately it was too late.

A description of other cases of brain tumor upon which I have operated will prove interesting in illustration of some of the statements I have made; this will therefore be given in the next lecture.

*(To be continued.)*

## ORIGINAL ARTICLES

### GASTRO-ENTEROSTOMY, PERFORATION OF THE STOMACH, PERFORATION OF THE INTESTINE, INTESTINAL OBSTRUCTION, AND SOME OF THE LESSONS THEY TEACH.

A paper read by special invitation before the Shelby County Medical Society, held at Shelbyville, Ind., April 8, 1895.

BY R. HARVEY REED, M.D., (UNIVERSITY OF PA.)  
PROFESSOR OF PRINCIPLES AND PRACTICE OF SURGERY AND CLINICAL SURGERY, OHIO MEDICAL UNIVERSITY; SURGEON PROTESTANT HOSPITAL, COLUMBUS, OHIO.

It is only a few years since stenosis of the pylorus, intestinal obstruction and gastric and intestinal perforation were considered fatal diseases. For the surgeon to have even suggested operative interference under the circumstances, would have only been to have incurred censure on the part of the medical profession as well as the laity.

During the last decade the advancement of surgical knowledge and the improvement of its technique has enabled the surgeon to invade the abdominal cavity, and handle it with comparatively the same

accuracy and confidence that the mechanic controls or repairs a machine.

When invited by your secretary to read a paper on this occasion, I was at a loss to know what subject I should select that would be of interest, saying nothing of benefit to the members of this active and progressive Association and its guests on this occasion.

At first thought it occurred to me that gastro-enterostomy would, perhaps, be of some interest, but on more mature reflection, I took the liberty of modifying my subject so as to cover two classes of conditions occurring in the abdominal cavity, and will, so far as I am able, illustrate what I may say on these subjects by specimens, and at the same time draw a few comparisons.

#### GASTRO-ENTEROSTOMY.

Gastro-enterostomy is usually performed where stenosis of the pylorus exists, whether of carcinomatous, cicatricial, fibrous or other origin. It is perhaps more frequently performed for cancer of the pylorus and may be of a radical nature or simply of a temporary character. Having determined by the symptoms which are familiar to you all, that obstruction of the pylorus exists, it is not always possible nor is it necessary for the diagnostician to determine absolutely before submitting his patient to an operation, the exact pathologic condition that is producing stenosis. From the fact that you have an obstruction, it is sufficient evidence to warrant an operation. If during the operation it is satisfactorily determined that the blockade is caused by cicatricial bands or by fibrous contraction of a benign character, it is not usually necessary to make an excision. Under these circumstances it is only necessary to "side-track," so to speak, this portion of the intestinal canal, by performing a gastro-enterostomy and thereby establishing a new opening between the stomach and the bowel.

Experimental research has demonstrated that where this can be done, that portion of the bowel which is thereby "retired from active service" becomes atrophied from disuse, and the digestive function of the gastro-intestinal canal is, as a rule, re-established through the new channel.

If we find by operative interference that we have a malignant growth to contend with, and it is possible to remove it, then it is necessary to perform an enterectomy, and remove all the diseased parts, closing up the stomach as well as the intestine under septic precautions, with a view of giving permanent relief.

If the growth is malignant and has involved the adjacent tissues to such an extent as to prohibit its removal, there is nothing left but to perform a gastro-enterostomy and contribute to the patient's comfort and length of days. As an illustration of this latter condition allow me briefly to report the following case:

Mr. F. B. P., age 52, a widower, was admitted to the medical ward of the Protestant Hospital, Columbus, Ohio, Feb. 5, 1894, for carcinoma of the pylorus. He was very much emaciated, could retain but little or no food, although hungry and anxious to eat, but when given any kind of food he retained it only a short time when it was ejected from the stomach and in consequence the patient continued the slow process of starvation. My attention was called to the case by Dr. Adams, who was then in charge of the med-

ical ward; an examination confirmed the diagnosis of obstruction of the pylorus which was probably due to carcinoma. Assisted by Dr. Means, he was operated on March 19, 1894, when we found a large carcinoma, which not only caused complete stenosis of the pylorus, but involved so many of the surrounding tissues that it was impossible to attempt to remove it. We therefore performed gastro-enterostomy, using the Senn bone plates. The patient rallied fairly well after the operation, notwithstanding his emaciated and debilitated condition. His appetite soon returned and for a short time he was able to eat and assimilate the more easily digested liquid foods, such as milk, beef teas and meat broths, to which were added, by degrees, a more substantial diet, which was not only relished but retained and digested. He was discharged the latter part of May, 1894, very much improved. I followed up the case and found that he was admitted to the Soldiers' and Sailors' Home at Sandusky, on May 29.

Through the courtesy of Dr. E. M. Heard, Assistant Surgeon at that institution, I received the following information relative to this case: After describing his general condition, the Doctor stated that he was nauseated after each meal and unable to take anything but liquids on account of nausea and discomfort. A physical examination revealed a cicatrix in the linea alba, extending from the center of which, was a small tumor of brownish color and firm consistency. Percussion revealed dullness over epigastrium, to right and above incision, about the size of an orange. The patient was put upon supportive treatment but gradually succumbed to the malignant disease and died from inanition on July 14, 1894. An autopsy was held eight hours after death, which revealed adhesions binding the intestines together but the abdominal wall was free. Duodenum firmly adhered to mass at pylorus. Upon opening the stomach, found a loop of black silk engaged in mucous membrane near the pylorus, and an opening admitting a lead pencil from the stomach to the intestines, evidently the result of an operation. At the pylorus was found a tumor broken down at a line corresponding with the junction with the stomach.

We will not take up your time going into further details of this case, except to demonstrate the feasibility of a gastro-enterostomy even in advanced malignant disease, which we believe is justifiable, and in a majority of cases will result in giving temporary relief, prolonging life, and also prevent the patient from dying the horrible death of starvation. Last, but not least, it shows what can be done when the peritoneum is protected from septic infection.

#### PERFORATION OF THE STOMACH.

On Dec. 24, 1894, I was called in the forenoon in counsel with Dr. Adams to see Mrs. J. M. B., age 32, married, no children, whom I found suffering agonizing pain. I inquired of her history and learned that she had suffered from ulceration of the stomach for over ten years; also had been troubled with uterine and ovarian irritation and irregular menstruation. She was in her usual health and attending to her duties about the house until 8 A. M., when she was taken with excruciating pains in right shoulder, left side and over the left ovary; also complained of tenderness along the spine. There was no fever, increase of pulse or bloating of the abdomen at 11 A. M., when seen by the writer in consultation with

the family physician. I was called again at 3 P. M., and found the pulse 120, temperature 104, when operative interference was seriously considered, for perforation of *some part* of the abdominal viscera. The obscure symptoms and reflex irritation, together with the history of her previous attacks of a similar character from which she recovered, caused us to hesitate. Subsequently, Dr. Baldwin was called in counsel, who agreed with us as to the probability of a perforation, but owing to the acute peritonitis, which had rapidly developed in the last few hours, it was decided that it was inadvisable to operate. The patient rapidly sank and died in twenty-six hours from the time she was first taken with the last attack. A post-mortem was held five hours after death, which revealed a violent general peritonitis the result of septic infection due to a large perforation of the stomach.

In order that you may more fully appreciate the condition which led to the perforation, I have brought the specimen with me and will pass it around for the benefit of those interested. You will observe the marked cicatricial contraction which has taken place about four inches above the pylorus and which has no doubt existed for years, but owing to the low vitality which we always find in cicatricial tissues, necrosis had taken place resulting in perforation and the escape of the contents of the stomach into the abdominal cavity. The practicability of operating on a case of this kind is quite uncertain as you will readily observe by examining the specimen.

You will note there is practically a large and small stomach, which are separated by cicatricial bands, through which the perforation has occurred. It would be quite impracticable to make an excision of this cicatricial portion, unite the lesser with the larger part of the stomach and expect the operation to be successful; and at the same time to attempt to close the opening by a plastic operation, we would have the low vitality which is always present in cicatricial tissue to contend with, which would surely be followed by necrosis and by another perforation.

The only operation which to my mind would present a reasonable chance of recovery in a case of this kind would be to excise the cicatricial band, together with the small portion of the stomach, and then after closing the stomach perform a gastro-enterostomy, and even this would be a difficult and hazardous operation, especially so when the abdominal cavity was so thoroughly infected with the contents of the stomach. It has been my experience that general peritonitis due to perforation is usually fatal in a very short time, no matter what you do.

In this connection I recall a case, which I attended while living in Mansfield, of a young man who had been complaining for several weeks of some stomach difficulty for which he had been treating with a homeopath, who had diagnosed it as indigestion. The young man had been at work all day plowing corn, ate a hearty supper, and a few hours afterward complained of a severe pain in the region of the umbilicus. I was sent for about midnight, found him in collapse with every evidence of general peritonitis; hands and feet cold, thready pulse, rapid respiration, etc. I diagnosed a perforation of the stomach with an unfavorable prognosis.

I did not think it wise to attempt an operation, although it was recognized only a few hours from the

time the perforation had taken place, owing to the escape of the septic material into the peritoneal cavity, and the violent peritonitis which had already set up. The young man died in less than twelve hours from the occurrence of the perforation. A post-mortem revealed a perforation of the stomach in the region of the large curvature, sufficiently large to allow me to pass my thumb through it, while the abdominal cavity was filled up with meat, potatoes, corn and other material which he had eaten for his supper.

#### PERFORATION OF THE INTESTINE.

Only a few days ago, March 30, I was called in counsel with Dr. Emerick to see Mr. P., aged 23, a sawyer who gave the following brief history: about 5 o'clock P.M., March 29, while working on a rip-saw he was struck with a board some three feet in length, seven inches in width and an inch in thickness which was hurled from the saw very violently, the end of the board striking him in the right iliac fossa. Notwithstanding there was not a mark to be discovered on the abdomen, yet there was all the symptoms of a perforation of the intestine accompanied with the usual prostration and collapse. He was admitted to the Protestant Hospital on March 30, and operated on that afternoon. Assisted by Dr. Means I opened the abdominal cavity and found it filled with fecal matter and enormous quantities of plastic exudation, the result of the most violent septic peritonitis, which had adhered the large and small intestines in one general mass.

An opening was found in the ileum about eight inches above the ileo-cecal valve and was sufficiently large to pass the thumb through with ease. The abdominal cavity was thoroughly washed out with sterilized water. The opening was closed with the Lembert suture, a drainage tube inserted and the abdominal opening closed with interrupted sutures. It is scarcely necessary for me to state that this case died in fifty-three hours after the injury and thirty hours after the operation.

We gave it as our opinion, before the operation as well as after it, that the prognosis was exceedingly grave, yet, at the same time I feel that it is the surgeon's duty, even in these extreme cases, to give the patient the last chance for escape from death. In this case we had some peculiar conditions to which I will now call attention:

There was not a mark of any kind to be seen on the skin. A small rupture could be felt through the abdominal muscle, but the parietal peritoneum was not torn, yet at the same time, the intestinal peritoneum together with the walls of the intestine sustained a large lacerated wound. I have seen several cases of this kind occurring in a similar manner, in which no external violence could be observed, yet the stroke was so severe as to cause a perforation of the intestine, and operation or post-mortem, as the case may have been, revealed a severe lacerated wound of the intestine.

#### INTESTINAL OBSTRUCTION.

Intestinal obstruction occurs quite frequently and is always a perplexing problem for the general practitioner. He, as a rule, is loth to advise a patient to be operated on, and especially so until he has tried all the remedies at his command from a medical standpoint, to relieve the obstruction. We must all admit that the diagnosis of intestinal obstruction is

quite difficult to make, even to the expert, in its early stages; how much more so must it be to the general practitioner who sees only a few cases in a lifetime. At the same time, I think we must all admit that where intestinal obstruction *does* exist, and where heroic efforts have been made to relieve the obstruction by severe and repeated catharsis and rectal injections, they, as a rule, contribute to the danger of the case by increasing the intestinal peristalsis and peritoneal congestion. At the same time, so long as there is no septic infection of the peritoneal cavity it will withstand a great amount of torture without fatal results.

I recall a case of this kind in which I was called in counsel by Dr. Adams, the attending physician, and found a lady aged 51 who had been suffering for several weeks with pain in the region of the gall bladder, but during the last few days prior to my visit, had every evidence of intestinal obstruction. The attending physician and I agreed in the diagnosis. She was admitted to the Protestant Hospital late on the evening of December 16, was gotten ready for an operation and was operated on the morning of the 17th. On opening the abdominal cavity we found the small intestine injected and dilated to fully double its natural size, while the ascending, transverse and descending colon was contracted until it was not larger than the normal ileum.

This condition of the intestine was a ready guide to the point of obstruction, and in a few moments I found the blockade, which at this time was complete and existed at the ileo-cecal valve. On examination of the cause of obstruction, I found a mass in the small bowel that was movable through the lumen of the intestine, which was filled with liquid matter. After having slipped the lump up to a point about a foot above the ileo-cecal valve, I then prepared to open the intestine and remove it. Dr. Baldwin who was assisting me, very kindly separated, as completely as possible the contents of the intestine from the mass and held the bowel firmly between his fingers on either side of it, at the same time holding the intestine outside of the abdomen to avoid infection.

An incision was made in the ileum large enough to allow the escape of the mass which, when removed, was nearly the size of a guinea egg. The bowel was thoroughly cleansed, the incision closed with the Lembert suture and the abdominal incision closed, and dressed in the ordinary manner. The patient made a rapid and uninterrupted recovery and was discharged from the hospital just seventeen days from the time she was admitted. On examining the mass (which has now become very much shriveled from desiccation) it was found to be made up of gall stones, fecal matter and apple parings, which in some manner had become cemented together into a firm ball, assuming the appearance of an enterolith and plugging up the ileo-cecal valve, and which would have caused her death had it not been removed. At this writing I am informed by Dr. Adams, she is enjoying her usual health and is attending to the duties of her household.

We do not propose to go into a general discussion of obstruction of the bowel, but we have another case which we wish to report, with a view of drawing some practical, clinical conclusions from this class of cases:

On the morning of April 3, 1895, I was called in

counsel by Dr. Beery who reported to me that he had a case of intestinal obstruction, which was admitted to the Protestant Hospital about 8 o'clock the same morning. The patient M. B., age 17, a tinner by occupation, reported that he had been troubled for some three years with constipation which at times was very troublesome, and during all this time he had been compelled to take some laxative in order to obtain a movement of the bowels.

On Sunday morning, March 31, he felt some colicky pains which grew worse, but his attending physician was not called until the next morning. The usual remedies were resorted to for the relief of the obstruction but without avail. An examination satisfied the attending physician, as well myself, that we had an obstruction to contend with and consequently an operation was advised. With the assistance of Dr. Baldwin, the young man was operated on between 9 and 10 o'clock A.M. on April 3. On entering the abdominal cavity, we found the lower portion of the ileum corresponding with a horizontal line across the umbilicus, collapsed and empty, while that portion above the horizontal line was distended. On further examination a firm band about a fourth of an inch wide was found, which extended from the descending colon across the abdomen to the ascending colon on a line with the umbilicus. There were neither parietal nor intestinal adhesions, except at each end of this band. The end extending to the descending colon was firmly adherent to it, while the other end was firmly fastened to a narrow piece of omentum which in turn adhered to the ascending colon. At the juncture of the band with the strip of omentum was found a tumor, which I have the pleasure of presenting to you, about the size of the end of your thumb and which was entirely free from adhesions and had the appearance of an organized hematoma. It was pedunculated and hung down from the band like a plum from a twig. This band was ligated at each end and removed with the tumor. The abdomen was closed and dressed in the usual manner, and the patient is making a rapid and uninterrupted recovery without an abnormal change of temperature or pulse.

Our diagnosis as to the character of the tumor was subsequently confirmed by Dr. Fraker, the pathologist of the hospital.

There are some remarkable features in this case, which have evidently been the result of a hematoma of the omentum setting up a localized inflammation, followed with cell proliferation, building a band in this peculiar manner across the entire abdominal cavity which for years partially obstructed the peristaltic action of the bowels, allowing only the liquid contents to pass, but finally became so firm as to cause a complete obstruction which would undoubtedly have been followed with death had not operative interference been instituted.

#### CONCLUSIONS.

In studying these cases from a clinical standpoint we find that they divide themselves into two general divisions:

1. Those in which we are warranted in giving a favorable prognosis.
2. Those in which we may expect an unfavorable prognosis.

In the first case, notwithstanding we had a carcinoma of the pylorus and performed a gastro-enter-

ostomy in an aged party, who was almost devitalized from starvation, yet the result of the operation was favorable, because we were enabled to avoid septic infection. In the fourth case we had an obstruction of the intestine, which was occluded by a fecal mass, causing severe enteritis with enormous distension of the bowel, yet by removing the mechanical obstruction aseptically, the patient made an uninterrupted recovery. In the fifth case we had a mechanical obstruction of a different type caused by a band, which was also operated on aseptically with the most favorable results.

In the second class, consisting of perforations, we have in the two cases reported, two perforations of the stomach, both of which died from acute, violent, septic peritonitis within a few hours after its occurrence. In the third case we had a perforation of the bowel, producing the same general results as those produced by the perforation of the stomach, each one setting up an intense septic peritonitis which resulted in death in a few hours, notwithstanding an operation was performed in the third case for its relief.

A study of these cases, leads us to the legitimate conclusion that we are justified in giving a favorable prognosis where there is an obstruction without septic infection but, on the other hand, where there is *perforation* and *septic infection* we are not justified in giving a favorable prognosis; on the contrary, we should look upon such cases with fear and trembling.

In conclusion, allow me to repeat that I believe it is the duty of a surgeon, even in the face of the grave conditions which usually arise in perforation of the stomach or intestine, to operate and to seek to make the operation at the earliest possible moment after the accident. Without an operation we have nothing to hope for. With an operation there is a possible chance of saving a human life.

## TUMORS OF THE EYEBALL.

(EXHIBITION OF SPECIMENS).

Read at the meeting of the Tri-State Medical Society, St. Louis, April 4, 1895.

BY WILLIAM H. WILDER, M.D.

PROFESSOR OF OPHTHALMOLOGY, CHICAGO POLICLINIC; PATHOLOGIST AND ASSISTANT SURGEON ILLINOIS EYE AND EAR INFIRMARY; OCULIST TO WESLEY HOSPITAL, CHICAGO.

The study of tumors of the eye is of the greatest importance to the general practitioner, as well as to the specialist, for the reason that not only is the special sense endangered, but the life of the patient frequently depends upon the early recognition and prompt treatment of a neoplasm of this part. Our time will not allow a consideration of the tumors affecting the lids, lacrymal glands and other adnexa of the eye, but it is the purpose of this paper to discuss briefly the most frequent growths that attack the eyeball.

Tumors affecting the cornea primarily are, from the nature of this structure, exceedingly rare. Usually they spring from the edge of it where the conjunctiva passes over into the epithelial layer of the cornea. Of the benign growths may be mentioned dermoid, which is usually situated at the limbus, involving both conjunctiva and cornea. Rarely it is seen on the cornea alone, as was the case with the small microscopic specimen shown here. It appears as a grayish, or yellowish-white, rounded mass varying in size from half a grain of wheat to that of a hazel nut or even larger. It is usually single but it

may be a double growth. Its surface is smooth and may be sprinkled with fine hairs. It is of congenital origin and supposed to be caused by an inversion of the epiblast. It is seldom cystic, as are dermoids of other parts, but is a solid growth containing hair follicles, elastic fibrous tissue, sebaceous glands and other histologic parts of cutaneous tissue. It is not malignant, and although growing slowly, is not likely to recur after a thorough removal.

The irritation of the eye from the scratching of the hairs, and the unsightly appearance of the growth, however small, usually bring the patient promptly to the surgeon. The growth should be cautiously shaved off the cornea with a cataract knife, and the base lightly touched with a cautery if it should show signs of recurrence.

The malignant tumors that affect the cornea are sarcoma and epithelioma. Sarcoma, seldom, if ever, begins primarily in the cornea, but takes its departure from the limbus or sclero-corneal margin. It is almost invariably pigmented, of the type known as melano-sarcoma, and makes its appearance at times in a small pigmented spot which may have been thought harmless. This part of the eye normally contains pigment, more noticeable in a person of dark complexion, in whom a distinct ring around the cornea may sometimes be seen. It does not always infiltrate the cornea, but often grows over it, although it can be demonstrated that the epithelial layer of the cornea passes up on to the tumor. It presents either a smooth or a lobulated dark brown appearance, is firm to the touch and bleeds easily because of its great vascularity. Often a tumor in this situation is an outgrowth from a similar mass inside the eyeball, that has infiltrated the ciliary body and sclera and extended its ravages to the structures on the outside of the globe. The prognosis is grave.

Epithelioma is a rather frequent type of growth in this neighborhood. This may be explained, according to Fuchs, by the predilection that epithelioma has for attacking those parts where the epithelial covering changes its character as it passes from one part to another. Examples are familiar in the frequency of epithelial growths about the anus, the lips and the eyelids. We have an analogous condition in the limbus, where the epithelium of the conjunctiva passes over to that of the cornea. A small nodule appears at the junction of cornea and conjunctiva, and grows sometimes with great rapidity. Although occurring in advanced middle life, it does not invariably do so, according to Saemisch, but may also occur in young individuals. This growth spreads over the cornea, but does not infiltrate it except when it is quite advanced. Even then it is quite easily removed from the subjacent corneal structure. It presents a grayish-white, nodulated, sometimes distinctly papillated appearance, and is accompanied at times with severe pain. Often these epithelial cancers are deeply pigmented and this form grows to a great size, separating the lids and projecting from the palpebral fissure.

The question of attempting to save the eye, when sight is not affected, by carefully dissecting away an epithelioma or sarcoma from the cornea is an important one. When the growth is small and has not invaded the corneal or scleral tissue, it may be tried with some hope of success, but I am skeptical that anything short of enucleation will suffice to check

these malignant growths. Under the microscope is a section of a small epithelial growth, removed about eighteen months ago from right cornea of a patient in the Illinois Eye and Ear Infirmary, but as he never reported again it is not known with what result.

It should be remembered that the nodule may be an outgrowth from an intra-ocular neoplasm. The danger of mistaking such a case for a localized sarcoma of the scleral region is not great if reasonable care is practiced.

Tumors of the iris are not common. Tuberculosis affecting this part appears usually in the form of reddish-gray tubercles situated at the root of the iris. These coalescing may form a distinct nodular mass, and with the increase of the growth there may be considerable pain, pericorneal redness and exudation into the anterior chamber. The growth may perforate the cornea or sclera.

Sarcoma of the iris may be of the pigmented or white variety; the former is the more frequent as well as more malignant. The disease may occur at any age; as a primary tumor of the iris it is rare, being usually an extension of a growth from the ciliary body. When the growth is of the melanotic type it is easily diagnosed. When of the white variety it may be confounded with tubercle, gumma or cyst of the iris. The former will probably show a conglomeration of tubercles of a dirty grayish color, situated at the root of the iris; a gumma will not be so distinctly circumscribed and there will be a syphilitic history, while a cyst will show a pearlish reflex quite characteristic.

These growths may be so small and circumscribed as to make it possible to successfully remove them by an iridectomy. This should be large enough to excise a considerable portion of the healthy iris around the tumor. At the first sign of recurrence, enucleation should be performed to prevent further spread of the disease. Cysts of the iris may be caused by either cysticercus or by the implantation of epithelial masses in the iris after a wound. We shall omit the consideration of them, as well as of navi, which are congenital black patches or elevations and extremely rare.

Of all tumors affecting the eyeball, those most to be dreaded occur in the choroid, ciliary body and retina. According to Noyes, tumors of the choroid are met about once in fifteen hundred eye cases. Eighty-five per cent. of such tumors are said to be sarcomata, and of these the greater number are pigmented. Sarcoma may also spring from the uveal portion of the ciliary body. (Lawford and Collins in an examination of one hundred and three cases, report six affecting the ciliary body, one in the iris, two affecting both choroid and ciliary body, and ninety-four originating in the choroid behind the ciliary body.) Usually the growth attains a considerable size before it is recognized, unless affecting primarily the region of the yellow spot, in which case the impairment of sight brings the patient promptly to the physician. It is customary to divide the clinical history of these cases into four stages, according to Knapp:

1. A period of early growth before there is any irritation.
2. A period of inflammation.
3. Perforation of the eyeball and extension of the tumor outside the eye.
4. Metastasis.

In the first stage there may be no symptoms unless, as said before, the tumor encroaches on that part of the eye which is used for distinct vision. In this stage there may or may not be increased tension; although, as a rule, it is increased. If the physician is fortunate enough to see the eye during the first stage he may, by an ophthalmoscopic examination, discover the growth. He will then see a mass within the eye with a comparatively smooth surface, over which the retina is seen to pass. The retinal vessels are convoluted because of the lobular condition of the tumor; and the retina itself is bluish-gray in color. A careful examination with a bright light may show that the tumor is vascular. The duration of the first stage varies from six months to four years. Fuchs found the average to be in sixty-seven cases, twenty-one months.

Most authors have found that males are affected rather more frequently than females. According to Lawford and Collins, 57 per cent. of the former and 43 per cent. of the latter are affected.

This is a disease occurring generally after the fortieth year; the average age of the 103 cases of Lawford and Collins was 48.42 years. The average of 259 cases reported by Fuchs was 44.2 years. The average of cases reported by Freudenthal was 49.4 years.

With the beginning of the second stage there are signs of inflammation. The eye becomes painful and tender on pressure, the tension is increased, ciliary region injected, anterior chamber shallow and all the symptoms of acute glaucoma are present. In this stage there may also be bulging or staphyloma of the ciliary region, showing that the growth threatens to perforate the sclera. An interesting point, with reference to the subsequent history, is that the prognosis is more grave when the tension is increased; *e.g.*, Lawford and Collins found metastatic processes more frequent in those cases presenting increased tension before enucleation, than in those in which the tension was normal.

In the third stage the tumor escapes from the eyeball and invades the surrounding tissue. The pain and distension that were present before, now disappear because of the relaxation of the tension. The mass grows with much greater rapidity. Unfortunately many of the cases do not come to the surgeon until this stage is reached, when the chances of an ultimately successful operation are greatly diminished. The optic nerve is invaded in at least one-fifth of the cases, and the prognosis is thereby rendered more grave.

In the fourth stage metastasis occurs most frequently in the liver, though it may occur in the lungs, brain, stomach, uterus, or other organs. Fuchs found that 18.5 per cent. of his cases suffered from metastasis. Hirschberg gives 38 per cent.; and in 32.9 per cent. Lawford and Collins traced death to this cause.

One of the greatest dangers to the patient is that of local recurrence, which is diminished if the eye is removed before the tumor has reached a sufficient size to cause increased tension and local irritation. As mentioned above, the tables of Lawford and Collins show that more cases are fatal when the enucleation is performed after the tension is increased than if it is done when the tension is normal. Once the growth has burst through the eyeball, the dangers are greatly increased.

Fuchs records local recurrence in 31 out of 235

cases or 13 per cent. Freudenthal found 25 per cent. of local recurrences, 6 out of 24 cases, while Lawford and Collins note 8.86 per cent.—7 out of 179 cases. The danger of local recurrence is greatest within the first year.

*Prognosis.*—Lawford and Collins in a report of 103 cases subjected to operation, were able to trace 79—of this number 39 or 49.36 per cent. were alive at the time of the report. In twenty of these, an interval of three or more years has elapsed since the removal of the primary growth, and these are considered to be probable cures. This gives a percentage of recoveries of 25.31. The averages given by other writers vary from 6 per cent. by Fuchs to 38 per cent. by Freudenthal.

Metastasis has been known to occur eighteen and even twenty-five years after the removal of the primary growth—but whether the tardy occurrence of such processes should be regarded as metastatic is certainly a debatable question. However, the possibility of such an event, even after the lapse of many years, should make the physician extremely cautious in his prognosis, even though the patient is apparently cured. The therapeutics of this question has naturally been considered in discussing the symptomatology and prognosis; it can be summed up in a few words—excise the eye as soon as possible after the diagnosis has been made.

Glioma is the only form of tumor affecting the retina. It takes its origin from either the inner or outer granular layer, and in its growth may involve all the structures of the eyeball except the cornea and the lens. Histologically it is closely allied to round-celled sarcoma, being composed of small cells, sometimes with short processes having a large nucleus and a small amount of protoplasm. It is difficult to demonstrate this protoplasm except on freshly prepared specimens. The intercellular substance is slightly fibrillar, but mostly composed of a semi-fluid material which gives the whole mass a consistency like soft brain tissue. The neoplasm is bountifully supplied with blood vessels. In its growth it attacks the choroid, causing a proliferation of the cells of that structure, and separating it from the sclerotic by spreading in the loose connective tissue between these two coats of the eye. In this way it may pass beneath the ciliary body and appear in the anterior chamber.

The tumor grows from the retina in clusters, well illustrated in the specimens, which give it a nodulated appearance often distinctly seen with the ophthalmoscope. Foci of the growth may develop in the vitreous and choroid and spread as independent tumors. After filling the eye the sclerotic is attacked, its fibrous tissue infiltrated and softened, until the tumor escapes from the eyeball and invades the orbit. Or, even before the mass has attained a great size inside the eye, it may find a way of escape through the point of entrance of the optic nerve, along which it then extends. Having escaped from the eyeball, the neoplasm takes on a more rapid growth in the soft parts of the orbit, and soon it presses the lids apart and presents itself as a hideous fungous mass which bleeds easily. Death may be caused by extension backward to the brain, or the exhaustion consequent upon the involvement of other parts, either by continuity or metastasis.

*Symptomatology.*—Clinically, this disease, like sarcoma, may be divided into four stages. In the first

stage there is no increase of tension and no irritation. The parents of the child may discover that it can not see with the affected eye, and that there is a whitish reflex from the pupil. This condition was named by Beers (one of the earlier ophthalmologists), "amaurotic cat's eye."

An examination of the interior of the eye with the ophthalmoscope reveals the growth with its nodulated surface, and possibly with the retinal vessels passing over it. Numerous smaller vessels in the tumor may be seen. As a rule, the vitreous remains clear.

In the second stage, symptoms of irritation and inflammation appear. The eye becomes painful, the tension is increased, the episcleral vessels are injected, the pupil is dilated, the lens and iris are pushed forward and the details of the interior are no longer distinctly seen. The cornea becomes cloudy and may ulcerate. In the third stage, there is perforation of the eyeball and invasion of the orbital tissues. The fourth stage ends the case with either extension along the nerve to the brain, or metastatic processes in the lymphatic glands or other organs, chiefly the liver.

This disease is one of early childhood, occurring very rarely after the age of 10 and with greatest frequency during the first three years of life. Well authenticated cases are recorded by Knapp, Hirschberg, Vetsch, Lawford and Collins, in which the disease was congenital. Furthermore, it happens in about one-fifth of the cases that both eyes are affected at the same time, this symmetrical occurrence not being the result of extension of the growth from one eye to the other along the optic nerve, but an independent affair. The prognosis is absolutely fatal unless the eye is promptly removed.

If excision is performed during the first stage, and before the growth has invaded the optic nerve, there is some chance of recovery. The chances of cure are very slim, however, when the operation is performed in the second stage, when irritation and inflammation have already begun; and when done after the tumor has extended to the orbit, there is almost no hope, although a few cases of so-called recovery are reported, even after complete exenteration of the orbit was necessary to remove the growth.

One should not hesitate to enucleate both eyes if the growth is bilateral, for cases of recovery after double excision for glioma have been reported. Even where there is absolutely no hope, it may be the surgeon's duty to remove the eye, and even the contents of the orbit, to relieve the little patient of his suffering.

103 State Street.

## PRE-COLUMBIAN LEPROSY.

BY ALBERT S. ASHMEAD, M.D.

LATE FOREIGN MEDICAL DIRECTOR, TOKIO HOSPITAL, JAPAN.  
NEW YORK.

Dr. Muniz, of Lima, Peru, alone of all the authorities known to me, thinks that leprosy did exist among the Incas; he finds evidences of this in some ceramics, the *huacos*.

In the *American Anthropologist* for January, there is an article entitled "The Huacos of Chira Valley, Peru," by Samuel Mathewson Scott. This valley was once teeming with population, though scarcely populated now. In this part of the country, there are numerous ruins and graves, and Mr. Scott's excavations among these monuments of the past, enabled him to make a collection of Peruvian antiquities, now

in the Museum of the University of Pennsylvania at Philadelphia. All the pottery found in those burial grounds are called *huacos*. They are found by the side of the mummies. "About the heads of the mummies, whether male or female, were ranged the pieces of pottery in black and red clay which are known as *huacos*. These were probably filled with water or *chicha*—a beer made from corn, the beverage of ancient Peru. Upon these jars the artists expended all their skill. The clay itself is very finely worked; the designs are infinite in variety and imitate every form of animal and vegetable life. There are jars in the shape of bananas, gourds and melons; there are jars ornamented with human figures, climbing monkeys, pelicans, parrots, fish and serpents. These is, moreover, a distinct tendency toward the comic and grotesque—many animals have exaggerated teeth, and birds have quaintly elongated bills."

It is on these vases that Dr. Muniz claims to have found figures which can reasonably, if they must not absolutely be explained, by the intention of the artists to represent leprous effects.

Dr. Brinton, of Philadelphia, kindly invited me to examine the Peruvian antiquities in the Museum of the University of Pennsylvania. Under these antiq-

*Huacos* pottery of the Incas without deformation.

uities can only be understood: 1, hands and feet of mummies; 2, the *huacos*. For skulls are out of the question. "A leprous cranium," writes Hansen, "shows nothing peculiar, as the skull is never affected by leprosy." For the purpose of comparison with mummies' hands and feet, Hansen sent me photographs. (He writes: "You can see the ossa metacarpi, especially the first and the fourth, atrophied, and also the distal phalanges; the curvatures of the fingers are to be seen too.") of a leper's right hand in two attitudes, from Dr. Kaurin's collection of leprous preparations at Rekna leper hospital, Molde, Norway. It belonged to an anesthetic leper.

There is a large collection of *huacos* pottery in the Museum of Archaeology of the University of Pennsylvania. I examined it with Mr. Stewart Culin, the director. In none of the specimens was there any representation of face, hand or foot which could in any way be supposed to be indicative of leprosy. I also examined with Mr. Culin, mound-builders pottery<sup>1</sup> from the stone graves of mound-builders in Missouri. According to Mr. Culin's opinion, these specimens are unquestionably anterior to the Conquest. In them the following evolution is shown: First, there appears the simple form in clay of a gourd.<sup>2</sup> Next, the gourd changes to the representa-

<sup>1</sup> The mound-builders were the immediate ancestors of American Indians.

<sup>2</sup> Gourds and shells were mound-builders models.

tion of the pregnant form of a woman, with the face of the woman on top. Thus the vase, which had begun with the original gourd, had become in course of evolution, a human form. Gradually this torso assumed hands, feet, backbone and buttocks. A similar evolution in ceramics, from the gourd to human forms, occurs in East Asia. I think I may make here an observation which will be superfluous for most readers, but which perhaps, will strike some as interesting. The gourd is the original vase of these nations. Naturally, when the artistic genius arose in their descendants, vases were made from clay, in the form of gourds. The idea of vegetable life, existing in the gourd, extended to the vase and developed finally into conceptions of animal life; thus was suggested the pregnant woman with the swelling belly, in

made up their minds to commit a sin they took care to turn the face of the earthen god to the wall. The mound builders, in order to leave nothing to chance, made their household gods with blind eyes; this at least is what the examination of these remains leads us to suppose. There are other vases in which the *penates*, as we may call them, have sealed lips, to prevent indiscretions. These blind eyes or sealed lips are the only deviations from the usual and healthy course of nature that I, at least, could discover in these monuments of prehistoric times.

The same evolution from the gourd to perfect human forms is found, as I said before, in East Asia. There leprosy is acknowledged to have existed for many centuries. Yet in the East Asiatic ceramics not the least trace of any intention to represent de-

Lepros Anesthetica. The right hand in two attitudes. From Dr. Kaurin's collection of leprosy preparations at Reknes Leper Hospital, Molde, Norway. Sent to Dr. Ashmead by Dr. Armaner Hansen for comparison with bones of Peruvian mummies.

a sitting posture. When the human representation had appeared it did not long remain limited to this feminine image; the male also was delineated. The development of the human being originating in the woman's womb, was shown in pottery through all its gradations: development of the face, then face and shoulders, then vases with face, shoulders and hands; feet succeeded, then all these parts with backbone added, developing through the clay; finally came the buttocks. In this way, the vase was endowed with life and became a household idol. The vase living, in the fancy of the people, was supposed to have its eyes on the affairs of the household; if they had

formations can be found. It is true that I have seen some deformations in the American Museum of Natural History, New York, but they certainly, whatever they are, are not leprosy; they may be due to syphilis, a disease which we know to have existed in Peru; syphilis and leprosy both would destroy the structures of the nose, and destroying the nose, would spare the upper lip. Now the deformations represented by these works of art show this: in three instances the cartilaginous part of the nose and the upper lip removed as by a knife, showing the septum and nasal bones and the soft tissues covering those remaining, and also the teeth; one figure lying prone upon the belly, with both feet gone to above the ankles. The nose and upper lip partly cut off, but both hands are perfect. Another figure

shows a partial loss of the upper lip, a semi-circular piece being cut out on the left side, teeth showing where the lip should have concealed them. This head is drawn far back—opisthotonus. Another one has the nose cut off, with the septum showing, and chin considerably drawn forward, a perfect mouth being at the top of it. Another figure shows a chin drawn strongly over to the right side with loss of upper lip. In all these figures the hands are perfect.

I regret not to be able to give photographs; but the explorer, Mr. Bandelier, the owner of these specimens, who is at this moment excavating in Peru, exacted before his departure, the promise that these articles should not be represented before he had finished his research. I asked the director, Mr. Saville, whether he thought, from his own investigations in

When the figure was placed upright we hardly knew what to call it, it appears so human, yet so apish. In the position it occupies it is 97 centimeters (about three feet) high. So if standing it would not represent a very tall person. It is made of white limestone and painted dark brown. The head is flat at the top and back, and apparently hairless, but painted blue, and over that are red streaks from the forehead down to the shoulders. The eyes are open, and painted blue around the lids. The nose is not pierced, but the clumsily made ears have each a large hole. The mouth is closed and lips painted red. On the back part of the top of the head a hole is pierced, so that a string can be passed through, perhaps to secure a bunch of plumes, perhaps to keep a banner in place, for in the palm of the right hand there is a groove as if for a round stick to fit in there. The hands are not altogether human; where the fingers begin there seem to be mittens, the other ends of which are nowhere visible. The fingers, like the toes, were furnished with nails made of shell, and fitted in place

Hands and forearm of Peruvian mummy, presumably pre-Columbian. Museum of Archaeology, University of Pennsylvania.

Yucatan, Mexico and Peru that these peoples would make representations of loathsome diseases on their pottery. He says that he has seen the coitus<sup>3</sup> represented in that pottery, and also some orgies, and that this disposed him to think that other matters might be represented which, in our own ideas, do not belong to art. He called my attention to a publication in the *Scientific American* in 1884, from Dr. Le Plongeon's discoveries in the ruined cities of Yucatan: "The figure (stone) was found on its back; one leg was broken off below the knee, but was found under the figure and afterward adjusted. The head of the statue rested on a stone painted red, that represented the tongue of a serpent, the peculiar shape of which Dr. Le Plongeon long ago discovered to be the letter *chi* or *ch* of the Maya alphabet.

Head of Peruvian mummy, presumably pre-Columbian. Museum of Archaeology, University of Pennsylvania.

with mortar so as to look very natural even in color. Unhappily nearly all were fallen, but we found some of them. A necklace is indicated by a line of red paint around the throat. Garters, below the knee, are painted blue and red. The loins are covered with an ornamental *wit*, a scanty garment yet in use among the aborigines, and anciently worn by Egyptian laborers. The right foot is turned in, as if the individual had been club-footed. The sandals are painted blue, and close up around the heel, but the very elaborate and fanciful fastenings are red. On one heel is the name, *Cay Canchi*, written with red paint. "This image," says Dr. Le Plongeon, "may possibly represent the sacred monkey of the Mayas, as the *Cynocephalus* was emblematic of the god *Thoth* among the Egyptians."

A monkey, even a deformed one, was thought worthy to be represented in stone. Mr. Saville suggested that it might be, not a monkey, but a leper, as the arms were cramped and the hands were in a clawed position, similar in some degree to that of a leper's hands (not mutilated).

Dr. Emil Holub, an African explorer who was present at the Museum, told Mr. Saville that he has seen

<sup>3</sup> I have seen a silver image from Peru, of a monkey copulating with a llama.

lips cut, as in these *huacos*, and something ornamental placed in the openings, in African Bushmen.

I may say that it would hardly be natural that art should represent loathsome features of nature, which could not be looked at without pain and perhaps horrible recollections. It was the idea of a correct human development that was in the mind of the potter, and what had the horrors of an awful disease to do with that?

It is clear that the non-existence of any leprosy characteristics in American antiquities is not a proof that the disease did not exist in this country anterior to the Conquest. The thing is simply this—*non liquet*.

Through the courtesy of Dr. Brinton and Mr. Culin, I have been permitted to examine closely the following Peruvian remains in the collections at the Museum of Archaeology, University of Pennsylvania:

1. The Scott collection, from Chirac Valley, Peru, to which reference has been made in the article published in the *American Anthropologist* for January: hands and feet of several mummies; post-Columbian, as shown by the presence of glass beads.

2. Dr. Carl Lumholtz' collection, from Chihuahua, Mexico: cave mummies' hands and feet, presumably ante-Columbian remains from burial caves (a very ancient form of disposing of the dead); North American Indian remains, presumably prehistoric, certainly several hundred years old; cave mummies' hands and feet from Nararachic, Mexico; remains from San Mateo, Peru, near Ancon, the most ancient burial place in Peru.

3. A lacquered mummy head from Ancon, Peru, with gold band over the mouth, presumably of a priest or sacred person carried over the country for worship according to custom.

4. A collection of loose bones of hands and feet from Cave Valley, Mexico (cave burial).

5. Apache bones, hands and feet, from Sonora, Mexico. (Apaches are thought by some observers to have East Asiatic (Tartar) characteristics and customs.)

6. Remains from a cave near Yocinbo, Chihuahua, Mexico, not ante-Columbian, on account of presence of glass beads.

7. A collection of perforated human bones, mostly humeri, from the mounds of Ohio. These perforations in the olecranon fossa were formerly supposed to be syphilitic; but they really are accounted for by the forcible extension of the arm, necessitated by the grinding of corn. In none of these bones was there any evidence of leprosy.

I examined besides, skulls from Choptauk ossuary, the sand bonepits of Dorchester County, Maryland, remains of Nanticoke Indians; nineteen casts of the Muniz collection of Peruvian skulls, showing ancient trephining, recently exhibited in the Smithsonian Institution, Washington; and skulls of Indians, excavated in Florida. These last are the only ones in which there can be perceived any evidence of disease; probably syphilitic osteitis, through intercourse with Spaniards.

There is a diseased skull in the American Museum of Natural History, New York, from an ancient grave at Lachay, near Chancay, Peru. It belongs to

the famous Banelier collection. On the left side of the frontal bone, near the median line, there is an egg-shaped, deep cavity, which does not penetrate the internal table of bone. This cavity has the appearance of having contained a hard smooth substance, probably a bone cyst, and the bone seems to have grown partly over the foreign body. Upon the parietal and occipital bones and especially on the frontal bone between the cavity and the orbit, are evidences of such destruction as might result from syphilitic osteitis. These evidences of disease, excepting the cavity in the frontal bone which, I may say in passing, has nothing to do with leprosy, are similar to those found in the Florida Indians. The latter evidently had contracted syphilis through their connection with the Spaniards of Mexico.

Mr. Culin informs me that there is one distinctly connecting link between the Mexican Aztecs and the Asiatics, besides that evolution of pottery which I have described above. It is the game of *patoli*. This game is played in Mexico thus: there is one stave held with the hand, across three parallel staves; it is used as a bat to throw beans or balls up to be caught, when falling back, upon a cloth; a tally is kept, according to the position in which these balls fall on the cloth. The three parallel staves are marked with an arrow, the single stave which crosses the parallel ones has the mark of a bow on it. The game was originally played not with staves, but with arrows, the warrior always holding three arrows with his bow. This explains the mark of the arrow on the staves. That the same game, absolutely the same, should exist in Asia can not be due to chance.

It seems to me that the intercourse, whatever it may have been, to whatever degree it may have existed, between America and Asia is the only thing which could, after what I have said before, make it admissible that leprosy existed here before Columbus came. Certainly syphilis existed here, and, if it did, it could not have come from anywhere else but Asia. Therefore, in spite of the absence of every proof of the presence of leprosy here, before the Conquest, we must consider the question as still in doubt.

The oldest center of leprosy in America, is Old Colombia, (Granada, Venezuela and Ecuador.) Carthagenia of the Indies was a most ancient focus of leprosy. Mr. Luther F. McKinney, U. S. Minister to Bogota says: "This country is cursed with leprosy, there being about 24,000 lepers in Colombia alone. Unless something is done to isolate those who are afflicted, and means taken to prevent the marriage of lepers, the whole country will eventually become a race of lepers."

The librarians of the National and the University Libraries of Ecuador, can find nothing for me, in any way connected with the origin and history of leprosy in Spanish America. These libraries are lamentably small and imperfect.

I am informed by the British Minister in the same country that all matters relating to leprosy have been extensively treated in Colombia where as I mentioned above, the disease is very widely spread. In Ecuador, he says the number of cases is comparatively small.

Dr. Zeballos, the Argentine Minister in Washington, writes that although he is a student of South American history he does not remember having read that leprosy existed among the Indians of his country previous to the advent of the Spaniards.

NOTE.—Brinton says: "But an obscurity certainly hangs over the ethnography of Florida at the period of the discovery. A large part of the peninsula was peopled by a tribe whose language stood alone on the continent, the Timucuas, and which became extinct generations ago. They are described by the Spanish and French explorers of the sixteenth century, as quite a cultured people and at that time as building mounds and erecting their houses upon them."

Dr. Juliano Moreira, physician to the Hospital Santa Isabel, Bahia, Brazil, says that the natives there before the Portuguese colonization, the Tupis, the Krars (Keras), the Goytacazes, the Guerens, the Gucks, the Parecos, the Guaycurus, the Lengoas and the Aruwacks, were certainly not leprosy and it is incontestable, in his opinion, that among the Indians now living, there is no disease that can be construed into leprosy.

Dr. Bibb, of Saltillo, Mexico, says that among the most prominent and best informed men in the city of Mexico, the general opinion is that the disease was introduced there by Chinese.

Dr. J. B. Terres, Vice Consul-General to Hayti, thinks that nothing has been written by any native of that island, nor by any foreigner, either as to the origin and history of leprosy there. However, it is supposed by old physicians, with whom the Vice-Consul spoke on the subject, that it was introduced by the Spaniards; but there is no proof of that. The same gentleman states that leprosy is very rampant in that island, and that no precaution whatever is taken to isolate the cases. There is no leper hospital, and the lepers are allowed to circulate without let or hindrance.

Dr. Beaven Rake (Report on Leprosy, Trinidad Leper Asylum, 1890) quotes from Leloir, page 300, that Drs. Magalhães and Mayrinch state that before the discovery of Brazil there was no leprosy among the Indians, nor subsequently in those who did not mix with the foreigners.

Beaven Rake says that of 216 lepers treated in the asylum, 74 or rather more than one-third were coolies. Of 138 reported from outside, only 29 were Hindus. No doubt there are more, for coolies when free do not seek medical advice so readily as other patients, unless they are paupers and wish to be maintained in the colonial hospital or leper asylum. "On the whole, then," says Rake; "the proportion of coolie lepers may be fairly taken as one-third. The question is, Where do they get the disease? We are told that there are some 250,000 lepers in India, and it is therefore hardly fair to suppose that all the Hindus who develop leprosy in Trinidad become infected here. It is far more likely that in some or many of them, the disease is already incubating when they land here, though it may not be evident enough to insure rejection after medical examination."

I have received a letter from Mr. McKinney, U. S. Minister to Colombia from which I extract the following:

"This country was first discovered (I mean Colombia) by a Spaniard, Gonzales Jimenez de Quesada, who started from the coast with a large body of men to explore the interior. He discovered the beautiful plain in which Bogota is situated, and founded the city of Bogota August 6, 1538. Some time after this, I do not know how many years, he was attacked with leprosy and died of it, I think about 1578. This was the first case known in Colombia, and attacked the first Spaniard who entered the country. In a late conversation with the acting Minister of Foreign Affairs, an intelligent gentleman, he said: 'Leprosy was not brought here by the Spaniards, but was developed here by the mixture of the races.' I can not see, however, that this can be true when the first Spaniard who landed in this country, contracted the disease and died of it. It seems very plain to me that this man had the disease in his blood, and it developed itself here. It is a well-known fact that leprosy had long before this existed in Spain, though at that time it is said to have been extinct. But while the disease is hereditary, it sometimes skips a generation, and this man may not have known his blood was tainted with the disease. This is the first his-

tory of leprosy in Colombia. "About 1550 a priest was sent by this same man to Africa, and he brought negroes to Panama and that was the first introduction of the black race into Colombia. (See note.)

"But from all the facts I have been able to gather, the leprosy can not be attributed to the negroes. There is very little pure blood of any race in Colombia; the people are a mixture of the Spaniard, Indian and negro races. Whether this mixture of the races, as some here assert, has caused the rapid spread of the disease, I am not competent to judge. There are in Colombia now, from 25,000 to 30,000 lepers; some put it at 60,000, but the weight of authority is in favor of the former numbers. The doctors here in Bogota declare universally, as far as I have talked with them, that leprosy is not contagious except by inoculation and heredity. But there are differences of opinion about this, and you are better able from your study of the subject to answer that question. Considering the large number of lepers in Colombia, the trade carried on with the United States, and the large number of Americans who are constantly coming here and returning to the United States, this is a matter of great importance to us, as it is likely in time to be carried to our country, especially as there is every year more or less marriage between the people of the two countries.

"I think one cause of the fearful spread of the disease is the poverty and filth of the people. Bathing is considered here more deadly than leprosy among the common people, and any filthy disease would find a congenial home among them. Another cause may be that the people are cursed with syphilis which was first brought among this people by the soldiers from Venezuela, during the early wars of independence. However, some say that those who have the one disease, are not so apt to take the other.<sup>4</sup> The government has so little money to expend for the purpose, that there is little done to isolate the disease, and though there are many schemes, and some hospitals for these unfortunates, they are scattered over every part of the country, and because of the laxity of sanitary regulations, they become beggars and vagabonds everywhere. I see them every day on the streets of this city. Unless something is done soon, the nation will become a nation of lepers and a menace to every civilized country.

"In my opinion the day will come when leprosy will command the attention of the medical profession of America, far more than it ever has in the past. May the day be far distant when our fair land will be cursed by such a loathsome disease."

(To be continued.)

## THE ANTAGONISM BETWEEN CITRIC ACID AND CANCROID CELLS.

BY C. M. FENN, M.D.

SAN DIEGO, CAL.

Though on the eve of another convocation, I venture to supplement the interesting discussion of malignant growths, held at the forty-fifth meeting of the ASSOCIATION, by calling attention to some original experiments inaugurated by the writer several years ago. The conclusions, with some additional cases, are now presented as a possible solution of the difficulties which so often militate against the radical extirpation of these and other neoplasms.

None will dissent from the dictum of the Section that early interference is to be commended, but unfortunately the scalpel, so far as the patient is concerned, is a *dernier ressort*, and not until he has exhausted other methods does he appeal to the surgeon.

It need not be remarked that from their inception, canceroid and other succulent tumors are environed by juices and cells, proliferations from the embryonic (?) germ which seem to await only the irritation of caustic or knife to migrate and set up foci of

NOTE.—The first negro in Peru was with "the thirteen" of the Isle de Gallo, before the Conquest, and in 1536 (two years before Quesada's time) Maroon negroes were in that country. The privilege was granted to Pizarro by the King, to import negroes from Africa before Quesada's time.

<sup>4</sup> That is the popular belief in Japan too.

infection elsewhere. May not these epithelial pearls, like the foliage of the agave, also contribute to the ultimate fruition of the central nucleus?

Fig. 141, page 528, of Virchow's "Cellular Pathology," while illustrating a solid mass of cancrioid from a tumor of the lower lip, graphically displays these cells *in situ*. The distinguished author in the same connection says, concerning the differential diagnosis of these neoplasms: "If you attempt to distinguish cancrioid growths from real cancer by the epithelial structure of their elements, you will herein give yourselves trouble in vain."

Hence, questioning the perspicacity of even the microscope, I am in the habit of classifying all facial tumors of the aged as at least suspicious and demanding immediate extirpation.

With the primary purpose of more accurately defining the boundaries of such growths, I employed a saturated solution of citric acid hypodermatically. It was found that the liquid introduced at any point near the periphery seemed to possess an elective affinity for the diseased structures and that it blanched and brought the same into bold relief. This will be recognized as a desideratum in operations about the face where the perplexing alternative usually presented is a sacrifice of symmetry or the probability of an early recurrence. Continuing the injections for several days, sometimes at the behest of the patient, it was further discovered that the area of induration and infiltration was measurably reduced. In some instances, as will be noted, no other surgical interference was required, and let me add that while the acid treatment enables the surgeon to make his incisions with greater precision and minimizes the danger of metastasis, it seems to be quite innocuous to normal tissues. The patient's experience is one of instant relief from the smarting and tension which attend certain neoplasms.

Among the cases previously reported was that of a man nearly 60 years of age, three of whose ancestors had succumbed to tumors of the face. In his own person a sessile growth as large as a filbert, having its apparent origin under the inner canthus of the left eye and leaving in its descent a broad cicatrix, was finally arrested at the junction of the ala of the nose with the cheek. In its new situation, enlargement became rapid and painful. Extirpation of the entire mass as outlined by the preliminary injection would have involved half of the nasal ala and not a little cheek, besides inviting profuse hemorrhages. Repeated instillation of the acid solution, during three or four weeks, reduced the dimensions to that of a small pea. The resultant scar was insignificant, nor had there been any evidence of recurrence up to the period of his accidental death six years later.

Another of the earlier cases was a so-called rose cancer which extended from one eyebrow to the other, and vertically more than an inch. Adequate incisions would have encroached upon both eyebrows, leaving an unsightly cicatrix at best. After a number of acid treatments the entire growth was included in an ellipse of no greater horizontal diameter than eight or nine lines.

Of more recent cases, I now note an undoubted epithelioma of the lower lip which involved a portion of the chin in its dart-shaped induration. Similar procedures relieved the chin and enabled me to include the remainder of the tumor in a small

V-shaped incision. Total extirpation in the beginning would have necessitated a formidable operation with plastic accessories. The gentleman's impatience alone prevented the attempt at radical cure with injections.

A further opportunity for testing the acid treatment occurred in the person of a lady over 60 years of age from whom I removed a scirrhus, left breast. Her financial condition precluded a lengthy sojourn in the city, and at the same time rendered any preliminary treatment impossible. Compensation for this was attempted by generously retrenching the flaps and bathing the parts subsequently with a strong acid solution. Union was delayed because of insufficient approximation, and some indurated portions of the integuments.

Yet a few injections *in situ* removed the latter, promoted healing and seemed to soften up one of the axillary glands which had escaped detection during the operation. A necessarily broad but healthy cicatrix was obtained in a few weeks, nor was there any recurrence at the wound site. Fifteen months later, the lady died of peritoneal dropsy which was regarded as metastatic and malignant.

More recently it was my privilege to treat a nose of generous proportions from which a Kentucky surgeon had excised a neoplasm some years before. After a brief respite it broke out again and again, and for the last two years had resisted all the blandishments of the *ars medicatrix*. Among other remedies, and notwithstanding his dual rôle of deacon and paterfamilias, some unbelieving Æsculapius had unsuccessfully subjected the gentleman to specific treatment. During the last few months of domestic or no treatment, its history was that of an open sore, either hemorrhagic in tendency and habit, or emitting sanious discharge which seldom rose to the dignity of a scab. Removal of the bit of paper which covered it revealed a raw, red and glazed surface, about five or six lines in diameter, surmounting an indurated base of much greater dimensions; in fact a typical epitheliomatous ulcer. Complete excision of the growth would have impaired the symmetry of the organ, by depriving it of the entire right ala. Hemorrhage and all unpleasant sensations ceased after the first injection, while cicatrization and atrophy proceeded *pari passu* until he was discharged cured.

In one instance, injections were thrown into the substance of a large colloid carcinoma, resulting in the disintegration of portions of it. It was too late, however, to prevent systemic infection or to arrest the growth.

## ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.  
NEW ORLEANS, LA.

(Continued from page 595.)

### CHAPTER IX.

ALTERATIONS OF THE BLOOD IN YELLOW FEVER, INDUCED  
BY THE SUPPRESSION OF THE FUNCTION OF THE  
KIDNEYS AND LIVER, AND THE RETENTION IN  
THE BLOOD OF THE CONSTITUENTS OF THE  
URINE AND BILE.

The constitution of the blood is more or less al-

tered in every case of yellow fever, but the changes are observed in greatest intensity in those cases in which there is partial or complete suppression of the action of the kidneys.

By careful experiments I have determined that during the active stage of febrile excitement in yellow fever, not less than 600 grains of urea are excreted by an adult during twenty-four hours. As the action of the kidneys is in many cases wholly arrested for various periods, ranging from one to four days before death, the whole amount of urea accumulating in the blood and remaining in the system may range from 600 to 2,400 grains. The gastrointestinal mucous membrane, in such cases, eliminates the urea, both as urea and as carbonate of ammonia; and both these substances frequently enter into the constitution of black vomit, which in many cases is intensely alkaline from the presence of carbonate of ammonia, in sufficient quantities not only to neutralize the acid of the gastric juice, but also to give forth such strong fumes as to be visible as a dense white cloud, when a rod dipped in hydrochloric acid is held over the black vomit, freshly discharged from the stomach or removed from the viscus immediately after death.

The presence of ammonia in the fluids of the stomach in such cases is clearly not due to subsequent changes, but is referable to the decomposition of the urea in the stomach, after the manner which has been pointed out by Frerichs, Bernard and other observers. In such cases the blood in the cavities of the heart and in the large vessels is black, and does not form a clot, and the solvent properties of the ammonia are manifest not only in the dissolution of the fibrin, but also in the altered appearance of the colored blood corpuscles, and in the rapidity with which they disappear when the blood is allowed to stand.

One of the most striking facts which arrests the attention of the observer in post-mortem examinations in this disease, is the apparent abundance of the blood in the various textures, its fluidity, and also the bright arterial hue which it rapidly assumes upon exposure to the atmosphere. This condition is referable to the distension of the blood vessel system, in consequence of the failure of the kidneys to eliminate the watery elements, as well as to the action upon the blood of the excrementitious materials. While it is true that urea is present in healthy blood in small amount, as may be determined not only directly by chemic means, but also by a simple calculation, as has been done by Dr. Goodfellow ("Lectures on the Diseases of the Kidney, generally known as Bright's Disease and Dropsy," London, 1861, pp. 67-69), I have at the same time, by careful analysis, shown that the urea is greatly increased in the blood of yellow fever, amounting in some cases to near 2 per cent. of the whole mass of blood.

The following is the calculation of Dr. Goodfellow, with reference to the amount of urea which must necessarily be present in healthy blood:

No physiologist denies that the urea is merely separated from the blood. It is universally acknowledged that the kidneys have no converting power. It can not be supposed, therefore, that all the urea contained in the blood goes directly to the kidneys; and consequently it follows, that only that quantity which passes through these organs is freed from this excrement at every successive revolution of the cir-

ulation. The following calculation will show this clearly: We will take the case of a healthy man, excreting every twenty-four hours about 360 grains of urea. This quantity divided by 24 gives 15 grains every hour, and still further reduced, one-fourth of a grain every minute. We will suppose the quantity of blood in his body to be thirty pounds, and that it takes from a minute to a minute and a half, to complete the circulation. We will suppose, moreover, that the kidneys constantly contain about three ounces of blood, and that about five ounces pass through these organs every minute. As we get, then, a quarter of a grain of urea from the five ounces passing through the kidneys, in this space of time, it is reasonable to infer that there will be left in the remaining mass of blood (475 ounces),  $23\frac{1}{4}$  grains of urea.

The quantities which Dr. Goodfellow has conjecturally assumed are, in the one case too small, and in the other too large, and he has subsequently added the following correction of the preceding calculation:

In one of the elaborate tables, in Dr. Parkes' work on the urine, it appears that the mean amount of urea secreted by males in twenty-four hours, as furnished by 250 analyses, made by twenty-four eminent chemists, is 512.4 grains, varying from 286.1 grains, the lowest, to 688.4 grains, the highest; and in females, from 260 to 400. The amount of blood (thirty pounds) is more than the area of the heart and blood vessels in a man of average size can accommodate, notwithstanding that it is the quantity as calculated by eminent physiologists. The amount of blood expelled from the left ventricle at each contraction, as supposed by Valentin (five ounces), and Volkmann (six ounces), is probably too large. The calculation is made on the supposition that at each contraction of the left ventricle from two and one-half to three ounces of blood are expelled, and that of the mass of blood so thrown into the aorta, from half a drachm to a drachm is propelled by the kidney, and that the same quantity makes its exit simultaneously by the vein. Supposing, then, that there are from seventy to seventy-five ventricular contractions in a minute, the total quantity passing through the kidney during this space of time, will therefore amount to from five to eight ounces. The calculation does not require the demonstration of the exact quantity which is always in the blood, but that there necessarily must be some urea constantly in it, and more than is generally supposed. The excretion of urea is always going on more or less quickly, and also the formation of this substance from the waste of the protein tissues, and from the same principles in the food, in greater or less quantity according to the state of the body, as to exercise or food; and as its transmission into the blood through its principal conduit, the thoracic duct (M. Wurst, as quoted by Bernard), is also constant, it follows that there must be more or less of urea in the blood at all times.

With respect also to the length of time required to complete the circulation, some facts of importance have been omitted in the calculation. Now that we have more correct notions with respect to secretion, most physiologists will show that although a complete revolution of the circulation may be effected in from a minute to a minute and a half, as deduced by calculation (Valentin and Volkmann), and by experiments (Poiseuille, Bernard and Blake), the blood really moves with varying velocity in differ-

ent secreting and excreting organs; influenced as the circulation is probably by the peculiar affinities, and the diameter and arrangements of the capillaries and other minute vessels. We observe that every secreting organ has some peculiarity in the arrangement and size of the vessels, and in the thickness of their walls. This arrangement must affect to some extent the velocity of the circulation, and affect also the character of the blood plasma transuded into the tissue, from which the secreting agents are to separate the peculiar constituents of the secretion. Taking the double circulation of the blood in the kidneys into consideration, then, it is probable that the blood does not pass through them so quickly as through some other organs, and that the whole mass of blood does not pass through the heart every minute or minute and a half, although a quantity equal to it may do so; some portions may, in fact, pass twice or oftener through the heart in this space of time.

On the assumption that there are twenty pounds of blood in a man's body, and that one ounce and a half of urea is excreted in twenty-four hours, Marchand calculated that the blood contained the 15-360 part of its weight of urea.\*

The results of these investigations on the condition of the blood, and upon the chemic constitution of black vomit in yellow fever, sustain the view held by MM. Prevost and Dumas, Claude Bernard, Ricord, and other physiologists, that urea after having been generated in the blood and tissues, is simply excreted by the kidneys, and does not confirm the doctrine taught by M. Herman, Dr. Beale and others, that urea and uric acid are not only eliminated but are formed by the renal tissue. And careful physiologic experiments which I have performed have been confirmed by the results of the inquiries of M. Gréhaut (*Archives de Physiologie Normale et Pathologique*, Sep et Novembre, 1870—*American Journal of Medical Sciences*, October, 1871, p. 530), which extended over several years. According to this careful observer, immediately after nephrotomy in the fasting dog, urea begins to accumulate in the blood, its increase being manifest within three hours after the operation; the increase of weight of the urea in the blood and in the lymph, twenty-four hours after the ablation of the kidneys, is equal to the weight of it that would have been excreted by the healthy fasting animal in the same space of time; the accumulation of urea in the blood in the hours that succeed nephrotomy, follows the same march as after ligature of the ureter. After ligature of the ureter, the quantity of blood circulating through the kidney of the side diminishes; under normal conditions the blood of the renal vein always contains less urea than the corresponding artery; in an animal in which the ureters have been ligatured, the renal venous blood obtained twenty-four hours after the operation contains as much urea as the renal arterial blood, so that the tissue of the kidney neither excretes nor secretes any more.

Finally, M. Gréhaut has shown, that ligature of the ureter and nephrotomy are two operations that are identical in their results; they both suppress the eliminative function of the kidneys, while they form no obstacle to the formation of urea, which takes place outside of the kidneys.

Whatever theory may be held as to the cause

of the peculiar phenomena, denominated uremia, whether that of the poisoning of the blood by the urinary constituents generally, or by urea especially, or by the product of its decomposition, viz., carbonate of ammonia, or by the edema of the brain from the accumulation of the watery constituents of the blood, attended by serous apoplexy and irritation of the brain and its membranes; it is evident that in many cases of yellow fever, the fatal issue is determined chiefly by the retention in the blood of the constituents of the urine. To this cause must be attributed to a great extent, the restlessness, nervous agitation, intoxication, delirium, convulsions and coma characterizing the stage of calm or depression in many cases of yellow fever.

NOTE.—Dr. Carl R. Braun, in his valuable work on the "Uremic Convulsions of Pregnancy, Parturition and Child-birth," has given the following summary of the state of our knowledge at the time of his work, which we here reproduce from the important bearing which it has upon similar phenomena in yellow fever:

"Eclampsia parturientium is commonly the result of uremic intoxications arising from Bright's disease of the kidneys, and produced mostly by carbonate of ammonia in the blood, perhaps also by extractive matters in the urine.

"This appears from the following analysis:

"a. All observers at present agree that urea retained in the blood is not, as such, the cause of the uremic symptoms.

"b. Lehman (*Physiol. Chemie.*, Vol. II, s. 245) and Frerichs almost simultaneously and independently of one another arrived at the conviction that cause of the uremic phenomena is to be sought for in the ammoniacal contents of the blood, produced by the transformation of urea into carbonate of ammonia.

"c. The investigations of Frerichs, Litzmann, the author (Dr. Carl R. Braun), Heller, Kletznsky, Ofpöizer, Gegenbauer, and others have demonstrated that in the eclamptic, urea and carbonate of ammonia developed by its decomposition are generally found in considerable quantities in the fresh blood, that from the presence of these materials in the blood the occurrence of uremic eclampsia may be prognosticated, and that these substances are observed also in the blood of children born of uremic mothers.

"d. Chemic analysis, however, can not always, even during the most violent eclampsia, discern the presence of carbonate of ammonia in fresh blood, as is shown in an observation made on August 4, 1854, by Gustav Braun and Heller and communicated to me. The blood, drawn from a vein after the sixteenth eclamptic fit, separated itself into clear serum and a light red, bulky, moderately consistent clot, covered with spongy fibrin, tinged yellow by a gall pigment. The strongly alkaline serum had a specific gravity of 1025, and contained much casein and bilephæin. The serum filtered after being treated with alcohol, contained little urea and sugar, much cholesterin and cholic acid. The blood then had not the uremic, but the cholemic constitution, as it contained no carbonate of ammonia, but all the elements of the bile. This observation, although it does not stand alone, can not be used to invalidate the theory of the very frequent coincidence of eclampsia and uremia. It rather points out that the excrementitious elements of bile may produce cholemia in the living body, and be likewise a cause of eclampsia.

"e. According to the very careful experiments of Mettenheimer (Mettenheimer, C., *Archiv. f. Voissenschriftliche Heilk.* 1. 4.), Beneke, and Reuling, (Reuling, W., *Inaug. Diss.*, Gussin, 1854,) all healthy and sick individuals have the power of expelling ammonia under certain circumstances. In the lungs of the healthy, ammonia is in general absorbed rather than expelled; hence the vapors produced in holding before the mouth a glass rod wet with dilute muriatic acid, are never capable of indicating the degree of uremia and Bright's disease.

"f. Normal blood when fresh drawn does not contain ammonia, as Reuling has proved by a very simple but very delicate qualitative method with logwood paper. In several diseases, as caries of the teeth, angina tonsillaris, typhus, pyemia, ischemia, and blenorrea of the urinary bladder, we sometimes find in the blood carbonate of ammonia, just as in uremia and Bright's disease. Hence carbonate of ammonia in the blood can not be regarded as a characteristic indication of uremia, and in many constitutions uremia may be produced by extractive matters in the blood.

\* Lectures on the Diseases of the Kidney, generally known as Bright's Disease and Dropsy, by S. F. Goodfellow, M.D., Ch.C., London, 1861, pp. 67-69.

"g. After weighing the objections raised against the theory of the intoxication of the blood by carbonate of ammonia, Litzmann has arrived at the following conclusions: the fresh blood of healthy individuals never contains ammonia. In the majority of the cases of uremia, the blood does contain ammonia, which has been formed by the decomposition of urea formed in the blood and retained in it, or by the decomposition of the urea that has been secreted in the urinary passages and has returned into the circulation by absorption. The presence of ammonia in the blood is indicated by the increased ammoniacal contents of the expired air; but this increase can not of itself be considered a proof, for it may be produced by the admixture of ammonia formed in the cavity of the mouth by decomposition of the oral secretions and of remains of food in the case of carious teeth, etc. In the vomited fluids and the contents of the intestine in cases of uremia, carbonate of ammonia is not unfrequently discovered. Sometimes there is an alkalin reaction of the sweat (Litzmann, Rühle). The urine may contain ammonia, even when it has an acid reaction (Brücke). But, on the other hand, presence of ammonia in the blood is not by any means a sign of uremia exclusively, for it has been exceptionally observed (Reuling) in other diseased conditions (typhus and pyemia) when the urinary secretion was not disturbed. On the other hand, cases undoubtedly occur where notwithstanding obstructed secretion of urea by the kidneys, and the occurrence of all the characteristic symptoms of uremia, the blood does not contain any ammonia and the ammoniacal contents of the exhaled air are not increased (Reuling), but when, on the contrary, undecomposed urea is found in the transudations from the blood, and in the sweat especially, may be in such quantity as to be left on the skin in the form of white crystalline dust. (Schottin, Archiv. f. Physiol. Heilkunde, Vol. x, xi, xii; Fiedler, De Secretion Urinæ per Cutum, Dissit. Inaug. Med., Leipsic, 1854). The cause of uremic phenomena can not therefore be sought for in the decomposition only of the urea retained in the blood into carbonate of ammonia.

"h. Whether the accumulation of extractive matters in the blood, in consequence of suppression of the urinary secretion is the cause of eclampsia (Schottin, Reuling) or not, is a question for the future to decide. Hoppe found, in a case of a uremic poison, besides urea, three times the usual quantity of extractive matters in the serum of the blood, and also the muscles saturated with their excretory products. The quantity of kreatin obtained from them was five times as much as the normal amount.

"i. Wiegner, on these grounds regards uremia not so loosely as the ancients, who held it to be a metastasis of the urine, and not so exclusively as Frerichs, who considers it an intoxication by carbonate of ammonia, but as a consequence of Brightian exudation into the kidneys which in its chemico-relations is characterized by retention of water and excrementitious matters in the blood, which itself, from the loss of blood corpuscles and albumin is impoverished in these elements. But it is uncertain whether the chief part in the combined operation is to be ascribed to the excess of serum or to the diminution of the albumin and blood corpuscles. Hydremia, however, is never the cause of the nervous symptoms, but has only a predisposing action.

"j. From the results of chemico-analyses it is certain that in uremia, carbonate of ammonia and urea are often found in the fresh blood and are rarely wanting. Although the essential nature of uremia is always coming into clearer light in consequence of the rapid strides of organic chemistry, yet we know enough already to assure us that eclampsia parturientium is always caused by the presence in the blood of an excess of excrementitious matters and also generally by uremic intoxication."

To the action of the same cause also may certain changes of the blood be referred, as the dissolution of the fibrin and the rapid changes which the colored blood corpuscles undergo after death and after removal from the living body. During the healthy action of the kidney, as has been shown by Simon, of Berlin, and Bernard, of Paris, fibrin disappears from the blood passing through this organ and is most probably converted into albumin, and the increase of the fibrin in Bright's disease has been referred to the cessation of this change of the fibrin in the diseased kidney; but in yellow fever, notwithstanding that the function of the kidneys may be

wholly arrested, there is almost complete disappearance of the fibrin of the blood, so profound is the action of the defibrinating cause. That very important changes take place in the blood during the healthy action of the kidneys, from the separation of the urea and other constituents of the urine, is evident from the fact observed by Bernard, that when the kidney is active, the blood issuing from the renal vein has a bright sparkling red color, but if the secretion is more or less diminished or altogether suppressed, not only is the blood issuing by the vein dark colored, but the whole organ assumes a purplish tint, more or less deep. This change of color has, with some show of reason, been referred chiefly to the non-separation of water during the suppression of the function of the kidney.

Nasse has shown that if blood be diluted with water it assumes a dark red color; if the blood be previously dark colored, it becomes still darker on the addition of water; and if the blood corpuscles be examined under the microscope, they are found to be distended, to have lost their discoid form, and to have become spherical; the blood collectively therefore must appear darker, since each individual corpuscle has become converted into a spherical mirror, from which the red rays are scattered and reflected.

It has been shown by the experiments of several physiologists, that when the red blood corpuscles are in normal amount, a certain quantity of urea added to the blood scarcely produces any effect upon them; but on adding the same quantity to the same amount of blood, from which a considerable number of blood corpuscles had been withdrawn, a very striking effect was at once observed—the corpuscles rapidly assumed a vermilion tint, and sank to the bottom, presenting the appearance to the naked eye of fine vermilion; and on examining this sediment with the microscope it was found to consist entirely of red corpuscles, reduced to about a sixth of their natural size. The effect of the urea seemed to be in exact relation to the quantity of red corpuscles in the dependent portions of the blood, resembling fine vermilion, as in the preceding experiments, and this appearance must not only be referred to the loss of fibrin, but also to the action of the urea.

The blood of yellow fever containing more or less urinous excrement, and with a physical alteration and actual diminution of both the albumin and fibrin, is not only ill adapted to the nutrition of the organs, and actually conveys to the stomach materials which when eliminated alter so completely the properties of the gastric juice, as not only to arrest digestion, but also to irritate and corrode the mucous membrane; but it is also by its physical and chemical constitution unsuited to the maintenance of the general capillary circulation.

Both Bernard and Poiseuille have observed that fibrin when in intimate mixture with a due normal proportion of albumin, facilitates the movement of the blood; but if the fibrin be withdrawn the blood globules fall to the most dependent part, and obstruct the capillary circulation.

Bernard has recorded the observation that when the capillary circulation in the web of the frog's foot is examined under the microscope, the globules are seen suspended nearly uniformly in the liquor sanguinis; but if we examine this circulation in an animal whose blood has been defibrinated, we see the globules fall to the most dependent part, while at

the superior parts, pure liquor sanguinis alone circulates. If a horizontal vascular trunk bifurcates in two divisions, not situated on the same horizontal plane, the lower branch will be plugged by the accumulation of the globules, while the upper branch will be full of serum.

Not only are similar causes active in producing the capillary congestions which are so characteristic of yellow fever, but the altered albumin and fibrin coagulate in the secreting and excreting structures of the liver and kidneys after its transudation through the walls of the capillaries and biliary and urinary tubes. To these changes of the blood, therefore, must be referred, to a great extent, the suppression of the functions of the liver and kidneys; for it is very evident that in the case of the liver the obstruction does not exist in the biliary or hepatic ducts, but in the biliary tubes.

It is evident that certain changes in the blood, as well as certain nervous symptoms in yellow fever, are due to the retention of bile in the blood.

Next to black vomit, jaundice occurring in the febrile stage of yellow fever is the most fatal symptom. Many observers regard jaundice as unfavorable in proportion to the earliness of its development; some writers considering jaundice as surely indicative of a fatal termination, when appearing upon the first or second day, or up to the third, fourth or fifth day.

Mr. Maher says that the period at which jaundice makes its appearance during the course of the disease is, according to the observations of Dr. Belot, a prognostic sign of great certainty. When it appears toward the third or fourth day, death will infallibly ensue; if it occurs toward the fifth or seventh day, the probability of a fatal issue is greater than that of recovery; finally, when it manifests itself only after the seventh day from the period of attack, recovery is almost certain (*Rapport Médicale sur l'Epidémie de Fièvre, Jaune*). The most valuable statistics with reference to this symptom have been furnished by Daniel Blair (*Some Account of the Last Yellow Fever Epidemic of British Guiana*." Third Edition, London, 1852, pp. 79-83). According to this accurate observer: "Yellow skin was always a sign of great intensity of disease. Among the 2,071 milder and graver cases, 385 had *yellow skin*; and of these 385, 178 died. Thus the proportion of cases in which the symptom appeared was 18.54 per cent., and the rate of mortality of the symptom was 46.23 per cent.

The following table will show the number of cases in which yellow skin was observed on different days of the disease, the number of deaths, and rate of mortality for each day, and rate per cent. of symptoms:

YELLOW SKIN AND BLACK VOMIT.					
122 Deaths.

Black vomit, although a very unfavorable symptom,

and more so than yellow skin, being as 75.68 to 46.23, is still not necessarily fatal. Out of the 366 cases of it, 277 only died, giving the centesimal mortality just stated, viz., 75.68. Yellow skin and black vomit were closely associated as to the time of their appearance, but the former was generally the antecedent (fortunate for the patient when otherwise). Thus in 139 ascertained cases, the former preceded the latter in 51 instances, appeared simultaneously in 46, and succeeded it in 42 instances. The double symptom of yellow skin and black vomit was of all others the most dangerous, and especially when the latter succeeded the former, and within twenty-four hours. The co-existence of these symptoms was observed in 144 cases, being 6.95 per cent. of the 2,071 milder and gravior cases admitted to the Seaman's Hospital. Out of these 144 cases, 122 died, making the mortality of the conjoined symptoms 84.72 per cent.

The following table shows the day of the disease on which yellow skin and black vomit occurred simultaneously, also the number of cases in which the former preceded or succeeded the latter, and the number of days it so preceded or succeeded:

TABLE SHOWING THE NUMBER OF CASES IN WHICH YELLOW SKIN WAS OBSERVED ON DIFFERENT DAY OF YELLOW FEVER, THE NUMBER OF DEATHS, AND RATE OF MORTALITY FOR EACH DAY.

Unascertained.	..	..	..	..	..	..	..	..	..

I have confirmed, by careful chemic analysis of the blood, and of the nervous structure and organs, the view held by some pathologists, that the yellow hue in jaundice observed in many grave cases of yellow fever is due to the presence of bile in the blood. By careful post-mortem examinations, as well as by attentive observation of the amount and chemic constitution of the urine in this disease, I have been able to refer the accumulation of the bile in the blood in this disease to two causes, viz., structural alterations of the liver, attended with desquamation of the excretory cells, obstruction of the biliary ducts, with altered fibrin and albumin and oil, and

the accumulation of free oil in the excretory cells, and structural alterations of the kidney, resulting in impairment if not total suppression of its function.

Bile is a very common ingredient of the urine in yellow fever, even in those cases which terminate favorably, and as long as the functions of the kidneys are fully and freely performed, the blood may be relieved from any great accumulation of bile, even when the lesions of the liver are well marked, and from this cause the urine may be loaded with bile. When the kidneys cease acting, the bile as well as the urinary constituents rapidly accumulate in the blood, and certain changes in the physical and chemical characters of this fluid are referable to the bile, as well as to the urinary constituents.

In order to ascertain the effects upon the various functions resulting from the absorption of a large quantity of bile into the blood, but particularly with the object of tracing what becomes of the bile in the blood—whether it is transformed, or is excreted as bile, and, if transformed, what may be the nature of the changes it undergoes—Frerichs performed a series of experiments, the general results of which were as follows: some of the animals died under symptoms of violent dyspnea (obstruction of the capillaries of the lungs), owing to the entrance of air into the lungs, or to the too great consistency of the injected fluid; twenty-nine of the experiments, however, succeeded in such a way that their results could be made use of. In no case did any remarkable derangements of the nervous functions follow the injection; in no case was stupor, convulsions or retardation of the pulse observable; vomiting, however, occurred repeatedly in about one-fourth of the experiments, and in some of these cases also the injection of the bile was followed by some drowsiness. The character of the urine which was voided after the injection varied; sometimes it contained a larger or smaller quantity of coloring matter, and at other times it contained none; the former was the case in nineteen, and the latter in ten, of the twenty-nine experiments. The urine containing coloring matter was always passed in small quantity; it was of a greenish-brown color, became turbid upon cooling, and then appeared green, rapidly depositing flakes which, under the microscope presented a finely granular appearance. When collected upon a filter, this deposit formed a dark grass-green layer, which dried readily, and which, when recently dried, exhibited the characteristic properties of the coloring matter of bile, becoming decomposed by the action of impure nitric acid, or by a mixture of sulphuric and nitric acids, with a lively play of colors of green, blue, violet and red. The reaction of the urine was, in most cases, neutral or alkaline; the removal of the flakes of coloring matter was speedily followed by an abundant deposit of triple phosphates; the specific gravity of the urine varied. When the kidney is examined after death, in these cases, the tubes are deeply tinged by the bile contained in their secreting cells, and some tubes are nearly or quite filled with cells which have been thrown off, while others have been formed upon the basement membrane beneath them.

Dr. Johnston concludes from these facts, that when the blood circulating through the kidneys contains an excess of bile, the renal cells, in striving to eliminate these materials, become deeply tinged by it, and many of them are so far modified as to be shed by a process of desquamation.

The bile exerts a direct effect upon the kidneys, without doubt, inducing congestion and desquamation of the excretory cells in yellow fever, but the albuminuria, hematuria, and even total suppression of the functions of these organs, can not be referred wholly to the direct irritant action of the biliary products, but must, as in the albuminuria and desquamative nephritis of scarlatina, be referred to other causes also, as the irritant action of the poisons exciting the diseases, and the morbid condition of the blood induced by the action of specific poisons, as well as by the altered bile. That the retention of bile in the blood is capable of inducing profound alterations in its constitution, is evident from the fact that in all cases of jaundice which last for a length of time, the blood becomes impoverished by a diminution in the proportion of red globules and fibrin, and a tendency is developed to hemorrhages from the various mucous membranes. While this tendency to hemorrhage is practically observed in conjunction with cerebral symptoms and other indications of blood poisoning in cases of jaundice, when there is no obstruction to the bile ducts, it also occurs in cases of mechanical jaundice of long standing, in which the immediate cause of death is not unfrequently copious hemorrhage from the stomach and bowels.

While Frerichs observed in his experiments no marked effects upon the action of the heart or nervous system, it is well established by clinical observation that the presence of bile in the blood frequently retards the action of the heart and diminishes arterial tension, the pulse becoming irregular and falling to 50, 40, or even 20, and presenting the same characters as the pulse in yellow fever; and it is equally well established that acute delirium, stupor, coma, muscular tremors and convulsions may supervene in cases of jaundice, where there is no obstruction of the ducts, as well as in cases of long standing mechanical obstruction. The fact that slowness of the pulse is not an invariable symptom of jaundice has been explained by supposing that it is due to one particular ingredient of the bile, which does not exist in the blood in all cases of jaundice. Thus, Röhring has shown by experiments upon animals that the biliary acid salts exercise a specific paralyzing action upon the heart and retard its action, while bile pigment has no such effect; slowness of the pulse, therefore, in jaundice has been referred to the presence in the blood of unchanged biliary acids. Notwithstanding that the blood of the human subject may be saturated with bile in jaundice, for long periods of time, without the manifestation of any serious cerebral symptoms, at the same time there are certain cases of suppression of the function of the liver, attended with cerebral symptoms of the most violent character, hemorrhage from the bowels, and profound alterations in the blood and urine, which can only be referred to the presence in the blood of the altered secretion of the liver.

The theory advanced by Dr. Austin Flint, that the cerebral symptoms in jaundice are due to the retention of cholesterine in the blood, does not solve the question; for if the retention of all the elements of the bile in the blood does not give rise to cerebral symptoms, it is impossible to understand how the symptoms can result from the retention of cholesterine alone, which is one of the constituents of bile.

Cholemic eclampsia, attended with jaundice, and

rapidly fatal tonic and clonic convulsions and coma, as well as that peculiar form of jaundice which is characterized by vomiting of blood, bloody stools, convulsions, coma and a rapid progress and fatal issue, evidently arise from the alterations induced in the blood by the constituents of the bile, and the products of their decomposition, resulting from acute atrophy of the liver, and present, not only in some of the symptoms, but also in the acute fatty degeneration of the liver, and infiltration of the organ with oil, and the alterations of the heart and kidneys, a striking analogy to the grave cases of yellow fever.

It is still a matter of dispute and doubt which element of the bile, or what products of the decomposition exercise the baleful influence on the nervous system in acute yellow atrophy of the liver. According to Frerichs, the formation of leucine and tyrosine, crystalline products of the decomposition of albuminous substances, may produce the nervous disturbances. Virchow, however, feels himself unable to grant this, because leucine and tyrosine are also found in typhus and exanthematous diseases, and may possibly be formed not until after death. Bamberger, on the other hand, thinks it more probable that they are produced by the acids of bile, and by the possible products of their decomposition; and Dr. Budd contends that they are due to some peculiar noxious matter evolved in consequence of decomposition, in the lobular substance of the liver; while Dr. Charles Murchison holds that the poison producing the cerebral symptoms is more probably generated in the blood and throughout the body generally than in the liver particularly.

The investigations of physiologists have shown that the liver not only excretes bile, but it forms grape sugar, and elaborates certain constituents of the blood, and exercises a continuous and important influence on the metamorphosis of matter constantly taking place in the blood and tissues.

That the arrest of the function of the liver checks or modifies the normal healthy metamorphoses of the blood and tissues is manifest, not only in the physical alterations of the blood in acute atrophy of the organ, but also in the great diminution of urea, and the appearance in large quantities of leucine and tyrosine, which possess a composition intermediate between it and the albuminoid components from which urea and uric acid are derived.

In acute atrophy of the liver, in acute phosphorous poisoning and in yellow fever, diseased states which have many symptoms and pathologic lesions in common, it appears that the albuminoid substances of the blood and organs, are split up into nitrogenous and non-nitrogenous combinations; but the combinations of the oxygen of the blood are not carried far enough to produce the final result of the normal oxidation in the healthy organism, and in addition to the formation of leucine and tyrosine, and of various nitrogenous substances, the composition of which is not perfectly known, fat results from these changes, which not only imparts an oily appearance to the blood, but also from the arrest of the oil globules in the capillaries infiltrates the textures of the liver, heart and spleen, and induces in these organs fatty degeneration.

(To be continued.)

## PERITONEAL SUPPORTS—(LIGAMENTUM PERITONEI.)

BY BYRON ROBINSON, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE SCHOOL.  
CHICAGO.

(Continued from page 598.)

The hepatic artery produces only a slight elevation of peritoneum until it reaches the hepato-duodenal ligament, whence it aids in giving distinct outline to the border of Winslow's foramen on the right. By opening an adult cadaver, well prepared for inspection, and then carefully incising the gastro-colic omentum, one can see with perfection the shape and form of the left opening of Winslow into the lesser omental bag. To obtain the best view of Winslow's foramen, however, the ribs on both sides should be removed and the stomach lifted well up. Winslow's foramen will then be seen to have a distinct oval form as seen from inside the lesser bag, whose circumference is nearly all produced by peritoneal folds projected by the gastric and hepatic arteries.

The splenic artery, I must say, contrary to some anatomists, does not run into the gastro-splenic ligament until it nears its termination. Beginning at the celiac axis it at first passes behind the ascending layer of the transverse colon or the layer forming the lesser omental sac. It passes along the upper border of the pancreas in a spiral manner. When it approaches almost to the spleen, it suddenly bends and gains entrance rather to the phreno-splenic ligament than the right gastro-splenic ligament for the only arteries which distinctly run in the gastro-splenic ligament are the vasa brevæ. This splenic artery does not make very prominent folds in the peritoneum, or what it does make are very short.

The spermatic vessels make evident projecting folds of peritoneum and give rise to the ligamentum infundibulo-pelvicum, which is a sharp fold of peritoneum transmitting the ovarian and spermatic vessels and nerves. The spermatic vessels give origin to the intersigmoid fossa which can be best noted, so far as my experience is concerned, in a spare infant of six months. In such infants one can demonstrate by pulling on these vessels, exactly the formation of the intersigmoid fossa. The deep epigastric artery produces peritoneal folds of varying sizes and is of no particular importance except directly at the origin, where the vas deferens and spermatic vessels pass around its outer side. At its origin a fold of peritoneum is often manifest and no doubt aids in the final passage of viscera in hernia. The fold frequently makes a depression, a fossa or peritoneal pucker, which predisposes to the formation of hernia.

The veins produce some interesting folds of peritoneum which call attention to anatomic and pathologic points. The ascending vena cava bounds posteriorly the foramen of Winslow, and in embryos and the dog the vena caval boundary is plain and suggestive as to the mouth of the lesser omental sac. It produces a large, round, peritoneal fold. The inferior mesenteric vein is of both anatomic and pathologic interest. In the first place this vein varies very much in its termination. It empties into the superior mesenteric vein at the junction of the superior mesenteric and splenic veins or, finally, it empties into the splenic vein. It can be observed how this vein shifts from the middle line (superior mesenteric vein) over to the left side (emptying into the splenic). It may be stated that as animal life ascends, this

vein moves toward the left to terminate, and hence the emptying of the inferior mesenteric vein into the splenic is a sign of higher life—apes and man. The pathologic interest in the inferior mesenteric vein lies in the fact that, as it gradually shifts to the left, in the ascending scale of animal life it forms a well-known fossa—the fossa duodeno-jejunalis, which generally is about the size of a thimble and occurs probably in about 60 per cent. of subjects. The fossa is situated at the junction of the duodenum and jejunum. I have observed cases where the inferior mesenteric vein passed nearly two inches to the left of the junction of the duodeno-jejunalis and in this case there was no fossa, but still a prominent peritoneal fold produced by the vein. Hernia is liable to occur in this fossa. The folds of peritoneum produced by fetal remnants of vessels are often large. The urachus, the remains of the allantois, does not generally produce manifest folds. The two arteriæ hypogastricæ may produce peritoneal folds over an inch high, especially near the bladder. Such folds could do no damage unless their mesentery either yielded, producing a pouch, or atrophied producing an aperture, allowing hernia to arise.

The round ligament of the liver, *teres-hepatica* passes from the transverse fissure of the liver to the umbilicus. This obliterated vein raises the peritoneum into a fold from one to two inches high. It acts as the *ligamentum suspensorium hepatis* and it is surrounded by a part of the anterior mesogaster. Should the *ligamentum suspensorium hepatis* become thin in any portion of its mesentery, a perforation might arise in it which might allow a loop of intestine to pass through it as frequently happens in the mesentery of a horse.

Again, raised folds of peritoneum due to blood vessels are not the only phenomena in the peritoneum attributable to blood vessels. We have large, thin and almost transparent areas in mesenteries which are due to lack of blood vessels. The areas occur among the arches of the vessels and especially at the lower end of the ilium in the region of the ileo-colic artery. The areas in the mesentery toward the center are very thin, transparent and devoid of any visible blood vessels. Such atrophic regions I have observed in man and dog, also horses who have a thin mesentery show very thin areas. I should suppose that the perforated condition of the great omentum is similarly due to the atrophy of the peritoneal tissue lying distant from blood vessels.

The nerves of the mesentery are derived from the abdominal brain or solar plexus. They run along the blood vessels ensheathing them. The bundles of nerves and great vessels continue parallel until the anastomotic vascular arches occur, toward the distal extremity of the mesentery, where the nerves begin to leave the blood vessels and cross the areas of the vascular arches. From the beginning of the vascular arcades the nerves do not lie parallel to the vessels, but assume an independent course to the bowel. The formation of a series of arcades leads to the separation and breaking up of the nerve bundles, after which many of the nerves reach the digestive tube by the shortest route.

Dr. Waite and myself, during two years, investigated some thirty bodies in regard to the viscera. In a spare body we could strip off a fine, transparent, epithelial membrane from each side of the small bowel mesentery. This epithelial membrane on each

side was so thin that one could not perceive it between the finger and thumb. It is the real peritoneum. After these superficial layers are stripped off from each side of the mesentery, a dense fibrous layer remains—the *membrana mesenterii propria*. The strong, white, tendon-like fibers in this mesentery proper are chiefly arranged in more or less thick bundles which gradually thin as they recede further from the arteries. The membrane is thick and heavy at the roots of the arteries, binding in a solid mass the nerves and vessels.

The *membrana mesenterii propria* is rigid and stiff at its base, preventing rotation or kinking of itself or of its vessels and nerves. As the membrane reaches toward the bowel it thins, loses many bundles of strong fibers and becomes more and more transparent. As it passes between the loops and arches of the arteries, by holding it up between the eye and the light, we can see the varying directions of the fibers. These tendon-like fibers are not precisely regular in distribution, and yet they have some regularity, like the direction of the fibers in a uterine myoma.

There are several layers of fibers running in gentle curves, always, thinning and disappearing as they become more distinct from the arterial loops. In the typical cadaver, by which I now sit and write, Dr. Waite and myself stripped off about a square foot of the superficial real peritoneal membrane on each side of the mesentery and by holding the long mesentery between the eye and a strong light, we could observe the various arrangements almost perfectly. It appears that as these fibers of the membrane proper, fill the space between the arterial arches and loops, they sweep in curves from one vessel to another. But the curving and interlacing fibers of the *mesenterii membrana propria* are firmly knit and bound into a tough layer, which holds with a firm grip the nerves and vessels in definite relation. Just as soon as the membrane reaches the bowel where it divides to receive the bowel, the connective tissue suddenly increases. In this body which lies before me, we could separate the superficial, peritoneal, epithelial covering from each side of the transverse meso-colon, but the *membrana mesenterii propria* in the transverse meso-colon is exceedingly thin and as transparent as glass, except where a large vessel was firmly embedded in it. The *membrana mesenterii propria* is very thin in the meso-colon transversum just as it is in the great omentum, or gastro-colic omentum. As the peritoneum passed upward from the upper layer of the transverse meso-colon, it passes over the pancreas, but a strong layer of the *membrana mesenterii propria* extends around the pancreas firmly imbedding it, for the pancreas is intimately attached to the peritoneum which lies in front of it, as it was once in the gastro-colic mesentery, as one can typically see it in the dog. Hence, we can say with much appropriateness in the actual examination of cadavers, fitted for the inspection, that the *membrana mesenterii propria* is the real mesentery. That it is simply covered on both sides by a thin layer of epithelial cells which constitutes the serous membrane. That this serous layer can be definitely stripped off. That the *membrana mesenterii propria* is the real neuro-vascular pedicle of the viscus at the distal end of the mesentery. That it firmly embeds vessels and nerves in its bundles of fibrous tissue which generally run in parallel lines or layers along the arteries.

One can prove that the chief bundles of fibers belong to the artery by dissecting out the artery when the mass of fibers will nearly all accompany the vessel. The great bundles of fibrous tissue are held together by a fine white tissue (connective), the same kind that surrounds each vessel and makes its snowy bed. No doubt this beautiful and useful arterial bed of areolar tissue, containing elastic fibers, saves many an artery from becoming an aneurysm, by equalizing its pressure and acting as a buffer against traumatism. It would appear that as we depart from the original primitive mesentery that the *membrana mesenterii propria* lessens continually, as for example, in the mesentery of the small bowel it is typical in size, strength and thickness; it is small and thin in the meso-colon transversum and finally in some parts of the great omentum it is scarcely visible.

In looking over the chief anatomies for one hundred years, it is evident that the mesentery has been viewed as a double layered membrane springing up from the dorso-abdominal wall. This membrane was indicating as inclosing the viscus and the vessels and nerves which keep it in existence. The same view I find in modern anatomies. The view is not so expressly stated, as implied, that the mesentery is simply a double layered membrane. It surprises me very much that I can find but little reference to the fact that the mesentery is a distinctly three-layered membrane, consisting of two thin epithelial membranes and one fibrous connective tissue layer—the three together constituting the mesentery, or the neuro-vascular visceral pedicle. That the mesentery has been viewed as a double layered membrane may be seen by examining the anatomies through Meckel, Hensing; Huschke (1797–1858, German anatomist and embryologist); Luschka, Henle and modern English workers. A work not at my command, but referred to by Professor Toldt of Vienna, shows that Thomas Wharton in his "Adenographic," published in 1656 (London) was the discoverer of the idea that the mesentery consists of three layers instead of two. Wharton writes that he, in the presence of Glisson, demonstrates the three layers of the mesentery on a 14-year-old girl, whose body was very spare. Wharton's discovery was confirmed by the anatomist, Verheyen in 1718. Toldt mentions that Bartholinus in 1686, and McEuler in 1746 are credited with investigating the three layers of the mesentery, in Haller's "Bibliotheca Anatomica" (1774). But the knowledge of these few anatomists seems to have been forgotten. In later times Ranvier, of Paris (1875) with his exact methods and brilliant results took up the subject and announced that the mesentery consisted of three layers instead of two.

In very early embryonic life the mesentery—a heap of cells along the intestinal canal—shows no indication of a double-bladed structure. But it appears as a simple bed in which run the vessels and nerves. It is faced with epithelial cells. In this aggregation of mesodermic cells gradually increases connective tissue and in the last month of intra-uterine life fat collects in the meshes.

The erroneous teachings of the old anatomists one would think would be buried with them, but one can easily see these errors propagated in modern journals. I refer to what the Latin anatomical writers curtly said in the short sentence: "*Organa intra et extra peritoneum sita.*" The development of the mes-

entery will dictate that all organs lie outside of the peritoneum. No viscus lies in the peritoneal cavity. Some surgeons gravely pretend to attack the appendix posteriorly to the peritoneum. Others with equal profoundness state that the appendix is an intra-peritoneal organ. These statements and many others in regard to intra-peritoneal organs are incorrect, for all organs lie entirely outside of the peritoneum. The organs can be enveloped by peritoneum, but are never entirely inclosed by it.

The mesenteries consist of two surfaces faced by smooth, shining, pavement epithelial cells. Between the layers of peritoneum composing the mesentery is a goodly amount of connective, elastic and often muscular tissue, which serves as a bed for the veins, arteries, lymphatics and nerves. A mesentery is of varying thickness, owing to the amount of fat and other tissue lying between the epithelial surfaces. In embryos it is very thin and as transparent as glass. In horses it is sometimes over two feet long and very transparent. Its use is to anchor organs to distinct points, to limit viscera to physiologic purposes by holding them in definite relations and allowing no entanglements or undue pressure. The mesentery is a highway for vessels and nerves and possibly the peritoneal covering aids digestion, sustains relations for ovulation and preserves conditions for expansion and contraction. The deviations of the mesentery from embryonic to adult life are the most manifest in the anterior and posterior mesogaster. Such changes affect higher mammals the most notably. As the stomach alters its primitive condition, the mesogastrium posticum or great omentum stretches out into a great sac, lying behind, to the left and below the stomach. This sac (*bursa omentalis*) generally hangs down below the stomach and covers the small intestines in most mammals. It has a varying relation to the colon transversum in the ascending grade of mammal life. The great omentum begins in most higher animals to embrace the transverse colon from the right toward the left as may be typically observed in the dog. The mesentery of the digestive tube lying posterior to the stomach retains a simple primitive character, especially when it is short. The mesentery of the carnivora with their short digestive tube is far more simple than of the ruminant with his long convoluted canal. The complicated mesentery chiefly arises in mammals who, from the nature of their food, require a long colon. It is the growth of the colon and its mesentery which destroys simple mesenteric relations. If the hind gut or colon grows it must grow forward from the neck of the navel loop and this quickly brings the colon with its mesentery in interfering relations with the lower and posterior end of the great omentum.

The mesentery either arises from the heaps of cells which grow around and inclose the gut, subsequently elongating into a double loop of membrane, or the mesentery arises by coalescence of intercellular lymphatic spaces from fluid pressure aided by independent action of adjacent walls—in short, cleavage, evagination, displacement, folding and coalescence of the mesodermic layer.

The mesentery of the small intestines (*mesenterium*) is a very variable element, as well as an important one. It is directed from the lower end of the duodenum across the trunks of the great blood vessels and the vertebral column obliquely, from left above to right below. The bony landmark is the second verte-

bral lumbar and the sacro-iliac joint. The soft landmarks are the lower end of the duodenum and the cecum. The mesentery consists of a right upper blade (*lamina dextra mesenterium*) and a left lower blade (*lamina mesenterium sinistra*). These two blades are in direct contact containing the nerves, vessels and lymphatics and connective tissue. The obliquity of the root (*radix mesenterii*) directs fluids on the right into the right iliac fossa and on the left in the pelvis. The mesenteric root in early life is situated high, but gradually descends with the progress of age, and after 35 may show distinct prolapse. The middle of the root of the mesentery and its lower end descends the most. However, much of what is known as visceral prolapse is mesenteric elongation. In fat persons the adipose deposit may reach one inch in thickness. At both of the mesenteric borders the blades diverge. At the root the right blade diverges upward over the transverse colon and laterally over the ascending colon. The left blade ascends over the transverse colon and laterally it passes over the descending colon. The left (under) blade alone descends into the pelvis. At the intestinal border both the plates of the mesentery diverge to inclose the small intestines. There is no fat between the peritoneum and the gut wall.

The mesentery in its strictest sense means that fold of peritoneum which holds the small bowel to the posterior wall of the abdomen. If we take the soft parts of the viscera as the landmarks of measurements, we will see that the mesentery begins at the lower end of the duodenum and ends at the lower end of the ileum. Should we take bony landmarks as a standard, the mesentery begins at the second lumbar vertebra and ends at the sacro-iliac joint.

The root or line of insertion of the mesentery is about six inches long and extends from the second lumbar vertebra on the left side obliquely across the spinal column over the great blood vessels to the sacro-iliac joint. The line of insertion is higher in fetuses than in adults. The average distance from the root of the mesentery to its embracement of the bowel is six and one-half inches. This measurement I have gained as the average from many cadavers.

At the upper and lower ends the mesentery has no length. Treves gives eight or nine inches as the length of the mesentery. Gray gives four inches. The second seven feet of the small intestine has the longest mesentery. Hence such coils may appear in hernia. The peritoneum constituting the right blade of the mesentery is continuous with the peritoneum which invests the under surface of the transverse colon and ascending colon. The left or under layer of the mesentery passes to cover the descending colon.

I carefully posted thirty-five adults and found in every case but one, that loops of small bowel could be dragged through a hernial orifice artificially prepared for that purpose. The mesentery is relatively longer in infancy than in adult life. In many adults during autopsy, I found that the mesentery had glided downward and prolapsed, and it seems that prolapse of the viscera increases with senility. The viscera do not generally begin to prolapse much before 40 years of age. Such prolapse tend to increase a subject's chances for hernia. My measurements give an average length of the mesenteric root or insertion in the abdominal wall as six inches. The average length of the small intestine, after many measurements, was about twenty-two feet. The

shape of the mesentery is that of a truncated cone, measuring six inches at the top and twenty-two feet at the base. It is fan-shaped. In the adult the base of the cone rests at the left side of the abdomen, while the truncated apex rests in the center along the vertebral column. Very frequently the transverse portion of the duodenum passes along the line of the mesenteric insertion for one-quarter, one-third or one-half of the distance. By lifting up the small intestines with its mesentery, one is often able to see the lower edge of the transverse duodenum. The line of mesenteric insertion is liable to considerable variation. In general, the line starts high on the vertebral column in embryonic and infant life, but after 30 years of age the mesenteric insertion gradually shifts downward until senility frequently shows a distinct prolapse. The breadth of the mesentery from the vertebra to the bowel is very variable. The most variable portion is at the lower end, yet likely much of the variation is due to prolapse or elongation. I have operated for femoral hernia when the lower three inches of the ileum was the strangulated loop. Generally the second seven feet of the small intestines have the longest mesentery. However, the variation from this measurement generally consists in the bowel still further down having a longer mesentery. The changes at the lower end of the mesentery concern the variation of the descent of the cecum. Suffice it to say here that if the cecum is non-descended, the deficit is made up by the ileum running over or up the psoas muscle to meet the partially descended cecum. If, on the other hand, the excessively descended cecum lies in the pelvis, it is liable to produce a more or less elongated mesentery at the lower end of the ileum. The upper end of the mesentery is complicated by the fossa et plica duodeno-jejunalis. A few days ago I posted a man of 60, where the fossa duodeno-jejunalis looked downward and to the right and would admit the tips of three fingers. The fossa was over two inches deep and would receive a large loop of bowel. Its free horn was over three inches long and contained the inferior mesenteric vein in its free border in a most typical form. The free border of the plica duodeno-jejunalis also contained the inferior mesenteric artery for about half its length. The extremely large fossa et plica duodeno-jejunalis was very obvious in this subject, owing to the vasa mesenterica inferior, but especially the inferior mesenteric vein. Hence the variation of the lower end of the mesentery is chiefly due to the non-descent or excessive descent of the cecum. The variation of the upper end of the mesentery is chiefly due to the variation of the fossa et plica duodeno-jejunalis. The variation of the whole mesentery is mainly due to fat, prolapse or elongation—senility.

It may be stated that the mesenteric attachment is acquired or secondary. We may recall the examinations of fetuses when the whole mesentery of the digestive tube was inserted in the mid-dorsal line, from diaphragm to caloea, *i.e.*, the whole bowel, large and small, had one common mesentery. This mesenterium commune was a straight unbroken fold hanging from the backbone, but growth of viscera and bowel and increase of abdominal space changes of mesenteric insertion are wrought until very little primitive mesenterial insertion remains. Even the meso-sigmoidea, which is named as primitive mesentery, is pushed from its original mid-dorsal insertion

toward the left iliac fossa. However, in infants as old as eight months, I have found the meso-sigmoidea distinctly inserted into the middle line as high as the under pole of the kidney which appropriates the original mesentery of the meso-colons descendens. In an adult the only real primitive mesenteric insertion belongs to the rectum. For, though the meso-sigmoidea and lesser omentum are still primitive, their original position has changed from the original fetal. Hence by changes in visceral growths, by rotation of the great intestinal loop, by displacement of the mesentery and perhaps by coalescence of peritoneal surfaces, we observe the wonderful changes in the original mesenteric insertions. We note that nearly all of man's mesenteric insertions are acquired or are secondary. The adult mesentery of the small bowel chiefly represents the changed mesenteric insertion of the distance between the neck of the great loop at its base *i. e.*, the loop supplied by the superior mesenteric artery. The acquired mesenteric insertion of the jejunum-ileum is closely associated with the transverse and last ascending portion of the ring-formed duodenum, for the superior mesenteric artery and vein in the adult passes in front of the transverse part of the duodenum (an acquired condition). In many cadavers I have found that the last portion of the duodenum seemed to lie at the base of the small bowel mesentery, in fact between the diverging mesenteric layers as they were inserted on the vertebral column where the layers of the mesentery received the superior mesenteric artery. I have found no reference to a discussion of this point in regard to the relation of the last point of the duodenum to the base of the small bowel mesenteric insertion. The most certain fixed ending of the superior end of the mesenteric insertion is near the pancreas, on the second lumbar vertebra or at the lower end of the duodenum. The most uncertain ending is the lower end of the mesenteric insertion which ends in a very uncertain manner in the left iliac region due to the various degrees of descent of the cecum. I have noted the ending of the lower end of the mesentery the whole distance from immediately under the liver to the pelvic floor.

(To be continued.)

## NEW INSTRUMENTS.

### BAXTER'S PORTABLE STEAM STERILIZER FOR INSTRUMENTS AND DRESSINGS.

BY G. A. BAXTER, A.M., M.D.

PROFESSOR OF SURGERY, CHATTANOOGA MEDICAL COLLEGE.  
CHATTANOOGA, TENN.

PLATE 1.—A, The complete package closed, showing outside telescopic case  $15\frac{1}{2}$  inches long,  $8\frac{1}{2}$  inches broad, and, when closed, 6 inches high. The case here shown is made of wood-pulp but may be made of canvas or leather. The telescopic character of the case allows other articles to be carried in it if desired, such as a Kelly rubber pad or an operating gown.

PLATE 2.—Steam chest for instruments and dressings with water-box attached by the handles of the latter to steam chest, ready for outside case.

PLATE 3.—Steam chest open and on its side, looking into its interior; large hole in bottom for entrance of steam, into which elevated flange on top of water-box fits; small hole in top of steam chest for escape of steam. The large hole below and the small one above gives a lateral distribution of the steam and considerable pressure. Both holes are fitted with screw caps for their perfect closure in transportation after sterilization is complete. Trays are provided for

instruments and dressings, which fit in steam chest. The lower has rounded corners for the upper to rest upon and is three and one-half inches deep for dressings; the upper one is one and one-half inches deep, for instruments. Both have per-

forated or wire bottoms for the passage of steam, and movable partitions fitting in slots, for the separation of dressings and to make more steady the instruments in transportation.

PLATE 4.—Shows bottom view of steam chest with flange

(one inch) to admit of application of elevated screw cap opening with screw cap for closure. On bottom of trays is shown small flange, one-third of an inch, to keep the bottoms of the trays from contact with surfaces upon which they may be placed, which fits them for operating trays also. There is a water-box one-half of an inch deep, holding about a quart of water for generating steam; with an opening in the center having an elevated flange like the top of a dinner bucket which fits into an opening in steam chest when in use, and a small opening with screw cap for the complete evacuation of the water-box.

In order to use this sterilizer, place dressings in the deep tray and instruments, sutures, ligatures, needles, etc., in the shallow tray and both in the steam chest. Fill the water-box; place steam-chest over water-box, which brings the elevated flange opening on the top of the water-box within the large opening in the bottom of the steam-chest, and fasten them together with the handles of water-box which catch on pin on end of steam box. Place both over any convenient fire, it matters not what kind, and steam

will generate soon (within five minutes or less by actual experiment over a good fire). This would give an outside time of thirty minutes as sufficient for sterilization of instruments and dressings, about the least time which would be required to prepare the patient and both could progress together in emergency cases as no special heating apparatus is required. If, however, in a previously planned operation it is advisable to make the sterilization at the office, the package can still be lessened by closing the openings in the steam-chest with their respective screw caps leaving the water-box at home. The weight of the whole package in either galvanized iron or aluminium is light and the closed package not bulky in the least. The dressings are not made soaking wet, but about the moisture of Linton moist gauze.

#### COST.

These sterilizers are made from either galvanized iron or from aluminium. For family use they can be made of tin and fitted with tray for bottles instead of instruments. When made from galvanized iron, the wire bottoms of the trays should be galvanized also, but the bottom and side of the water-box should be of copper. Such is the one I have in use, made by a tin establishment of this place and costing \$5 including the outside case. They can be made in aluminium at a cost of \$15.

NOTE.—This cost in aluminium is an actual bid from a reliable firm for the manufacture of the first one in this

metal. I can affirm positively that they can be sold with a fair profit at or very near this price, and as my only desire is the aid to my professional brothers I will agree to communicate this offer to any respectable instrument-maker who will agree to keep the price of the instrument down to a reasonable profit upon them.

#### BAXTER'S SWING SUPPORT FOR BADLY INJURED HAND OR ARM.

The above swing support I have found a very great convenience in a large class of injuries occurring in my work among railway employees. It gives no pressure upon the hand in any way, and holds it as steadily as if it were at the side in bed. I have shown this to a number of physicians, some of whom have remarked: "I have seen that before;" but upon reflection have declared themselves mistaken and said that they supposed it was its simplicity which gave them their first impression. If it is not a new device, I have been unable to find a report of its use anywhere

in the surgical references at my command, and it should be more widely known for its convenience, as it will keep many a case on foot which would otherwise be confined to bed.

## SOCIETY PROCEEDINGS.

### American Electro-Therapeutic Association.

*Fourth Annual Meeting held in New York Academy of Medicine,  
New York, Sept. 25, 26, and 27, 1894.*

WILLIAM J. HERDMAN, M.D., President.

(Continued from page 558.)

GEORGE GAUTIER, M.D., of Paris, France, presented a paper on

#### METALLIC OR INTERSTITIAL ELECTROLYSIS.

Interstitial or metallic electrolysis is a use of the galvanic current that has many applications in electro-therapeutics. Personally, I have been experimenting for three years with this therapeutic application of the current, with a view to define more clearly its method of application and demonstrate its use to physicians.

Interstitial electrolysis takes place each time that we connect the positive pole of a pile or of a Gramme's, Siemen's or other machine with an oxidizable electrode of copper, zinc, iron, manganese, aluminium, etc., or when we decompose a solution of potassium iodid by the anode.

The electrolytic products, which are different at each pole, can be made use of in two different ways; either they can be absorbed in great part with the help of oxidizable electrodes, or they can be diffused through the tissues with the help of unoxidizable electrodes. We have at the positive pole different effects produced on the tissues, according to the nature of the electrode and the decompositions that

take place there. Thus with coal we produce a lesion deeper than with platinum and gold, which afterward suppurates and takes on all the characters of the cauterizations made by acids, fire or the thermo-cautery.

It is on this particular action that Dr. Tripiet founded an important branch of electro-therapeutics; I speak of electrolysis or cauterization and destruction of living tissues by the continued current. With oxidizable electrodes we have no destruction of tissues. We have here instead a decomposition, giving rise to new compounds which are diffused into the tissues according to the direction and intensity of the current. With iron we obtain an oxid, with zinc and copper a chlorid and an oxychlorid. If we kill the animals that have served for experiments in metallic electrolysis with copper, we find oxychlorid of copper in places distant from the point of application, and the coloration shows that the diffusion is greater according to the length of application and the intensity of the current. I have some time since made a study of these different operative factors, i. e., the current's intensity and duration, and have noted especially that operations of this kind produce neither destruction of tissue nor suppuration. Since then, several years have passed, and I now wish to present to you a method of treatment whose value increases according as it is well known and above all well applied.

I prefer copper for the oxidizable electrode and rarely use the zinc electrode, which has no advantage and possesses certain disadvantages, especially that of causing pain. Iron is indicated in the treatment of fibromata without any inflammatory lesions of the adnexa or of the uterine mucosa. In this case one avoids partially the cauterization that takes place in galvano-chemic cauterization or when the operator uses platinum or charcoal for the electrode.

The electrodes of pure copper are, according to my experiments, the ones that give the most rapid results in a great number of cases. I can not in this summary note describe all the applications of cupric electrolysis which I have made. The physicians who devote themselves to electro-therapeutics know that I have endeavored to generalize the use of this method and that to make more varied its uses there would only be necessary a few changes in the *modus operandi*, such as was described by me two and a half years ago. The following objections have been raised to this method of treatment:

1. Cupric electrolysis is said to be very painful. Indeed, it causes uterine pains which last sometimes three days; these pains are caused by the formation of gases or by a certain degree of inflammation of the mucosa. Thus in chronic inflammatory diseases of the uterine mucosa, the patient feels after the sitting general pelvic and lumbar pain, which diminishes the first day after the operation and disappears on the second day; there is then a discharge of mucus and little clots of blood, and on the fourth day there is relief from all the pains of disease felt before the operation. These post-operative pains can generally be relieved by an injection containing laudanum.

2. Cupric electrolysis is said to predispose to hemorrhage. I maintain, on the contrary, that the method is the best treatment against hemorrhage. After the sitting we have often a slight flow of blood, even for two or four days, but afterward the effects of the treatment appear, the congestion is diminished and the vascular tissues are contracted. Thus in chronic metritis, characterized by hyperplasia of the uterine connective tissue with an increase of sensibility, we can verify, after one sitting of cupric electrolysis, the most marked improvement. The menstrual flow is subsequently diminished, the sensibility disappears and the patient is greatly relieved. These post-operative reactions are easy to study in external applications. In syphilis, for instance, the lips are swollen the first day; on the second large greenish serous patches are seen at the seat of puncture; after that the skin becomes normal in color and very supple. But the treatment of external hemorrhoids shows most clearly the effects of the oxychlorid of copper. When we puncture a large hemorrhoid, the same evening the veins are dilated and swollen, the third day they are scarcely visible. In this case also there is a slight flow of blood, but this is of slight importance, as the hemorrhoid so treated remains permanently cured.

Others will explain better than I, the therapeutic action of the oxychlorid of copper. It destroys inflammatory tissues, reduces quickly and effectually local congestions and finally possesses a real antiseptic power.

#### DISCUSSION.

DR. A. H. GOELET said that another year's experience with

metallic electrolysis in uterine disease served to convince him more firmly of its value in this particular class of cases. His views had, however, changed somewhat in the past year, in that he very much preferred zinc to copper. He believed that Gautier had pointed out some time ago that the insoluble salt of copper, referred to by Dr. Morton, was deposited beneath the surface, and this would explain why the benefit was not always apparent at once. Last November he had been asked by Dr. Bryant and Dr. Lusk to see a case of persistent and obstinate hemorrhage complicating a fibroid tumor of the uterus which illustrated the delayed action of this method of treating uterine hemorrhage. Dr. Lusk had already curetted but without arresting the hemorrhage. The speaker said he made four applications of cupric electrolysis in this case and observed only slight improvement at first, but advised a little delay. One month later Dr. Bryant told him that the hemorrhage had gradually ceased. Six months later he reported that the patient was apparently perfectly well and there had been no recurrence of the bleeding. The fibroid still remained.

Dr. Morton had said that we may use any metal, but he, Dr. Goelet, thought the salts of iron were too irritating. The same might be said of cupric electrolysis as the primary effect of the copper salts were highly irritating, and in the vagina even produced excoriations. The result of zinc electrolysis was the formation of an oxychlorid of zinc which was not only antiseptic but caustic, an action often desirable. The fact that the zinc electrolysis does not cause the electrode to adhere to the surface to which it is applied as does the copper is a great advantage in its favor. Where astringency was needed, he had used silver, because the silver salt was astringent without being very irritating, and without causing the disagreeable adhesion to the tissues. He considered cupric electrolysis particularly advisable in cases of septic endometritis where for any reason it was considered unadvisable to curette. He had had a number of cases in his clinic where septic endometritis had been overcome by a half a dozen applications or less. He recalled particularly a case of distinctly gonorrheal origin which was completely cured by six applications of this kind. The case had been kept under observation for many months so as to be sure of the permanency of the result. In these cases, as well as in uterine hemorrhage, he now preferred zinc, as the result was more promptly reached and there was none of the disagreeable irritation which followed cupric electrolysis. Another application of cupric electrolysis which has not been mentioned, was in the treatment of vulvo-vaginal cysts after evacuation of the contents of the cyst. These cysts were obstinate in healing under the usual treatment, but under cupric electrolysis with a current of from 20 to 25 milliamperes applied for five minutes, one or two applications usually sufficed to effect a cure. In making use of these metallic electrodes in the uterus, it was necessary that the electrode should be in close contact with the tissues. Realizing that Gautier's electrodes were inconvenient, he had had some electrodes made which he exhibited. The hard rubber handles were so shaped as to indicate the direction of the point of the instrument. The vaginal part of the instruments were insulated with soft rubber tubing, which by moving on the shaft allowed a larger or smaller surface to be exposed for action.

DR. MARGARET A. CLEAVES said that she had had the same experience as had Dr. Goelet, regarding hemorrhage persisting for a while after the treatment and then stopping later on. If the applications were made about the time of the menstrual period there was apt to be an exaggeration of the menstrual flow, but subsequent periods were more nearly normal. In endometritis associated with dysmenorrhea, she had in three or four treatments given complete relief. She was also more inclined to use the zinc than formerly, particularly in cases of erosion. She had treated trachoma in the third stage by means of zinc electrolysis, and the improvement had been very marked and permanent, although only a few applications had been given. Gautier said that iron was indicated in fibromata, providing there was no inflammatory condition in the neighborhood. She had used aluminium for a few months past in endometritis, but was not prepared to speak as to its value. She continued to use cupric electrolysis in atrophic rhinitis with success, also in follicular pharyngitis. In several cases of acute follicular tonsillitis a single application of cupric electrolysis, 3 to 10 milliamperes, had resulted in complete resolution. In an epithelioma with extensive ulceration, she had had relief from symptoms, and tendency of ulcerated surface to heal from margins and bottom, from two applications of cupric electrolysis, but had not been able to follow the case

up and could not give ultimate results. In a case of beginning suppurative in a nurse's finger, from infection, a cupric puncture with 2 to 3 milliamperes of current established resolution. In specific urethritis in the female, she continued to find it prompt and efficient in action.

DR. WALKER said he had had a case in which he thought this treatment would show the advantages of metallic electrolysis. A lady, ten years married, suffered from excessive menorrhagia every two weeks. All medicinal means had been used before he saw her. Copper electrolysis was tried between the periods and was followed by extreme menorrhagia. As the next period was no better than the previous one, another application was applied given in the interval. This was followed by much the same result. With much difficulty she was persuaded to submit to still another application. The result was the same, and the electrical treatment was discontinued. After this menstrual period, as she was going to New York City, she was advised to call upon Dr. Goelet, but a few days ago she had come into his office and reported that she was well. She said that she had not been to Dr. Goelet's because her next period had lasted only seven days, and the next only five, so that she did not deem it necessary to seek further advice.

DR. O. S. PHELPS, of New York, said he wished to report a case in which this treatment had been tried. It was one of mucous cysts of the tongue occurring in a patient 25 years of age. The tumor was about the size of a hen's egg. It had been operated upon once in Germany and several times in this country, so far as could be ascertained, by evacuating the cyst and by injecting iodine and similar remedies. The speaker evacuated the cyst and made two applications of cupric electrolysis about five days apart. The result was a perfect and permanent cure. The Doctor also exhibited a set of ellipsoid electrodes which he considered quite a triumph for the instrument-maker. They were made by depositing copper on hard rubber with the idea of avoiding the great weight of an electrode made entirely of metal. The particular form of the electrode had been selected because with the egg-shaped electrode he had found that it was often difficult to withdraw it in cases of urethritis.

DR. DICKSON asked Dr. Goelet as to the present status of cupric electrolysis in the treatment of uterine fibroids.

DR. GOELET said that his personal experience had been that cupric electrolysis was only useful in the way of controlling hemorrhage and that no greater reduction of the size of the growth had occurred than with ordinary electrolysis. He had found that zinc would control the hemorrhage just as well as copper, and the beneficial effect was more quickly obtained. Others had had a similar experience. Zinc also affected, more materially, the size of the growth.

DR. J. J. PUTNAM asked what was the effect upon cell growth of this deposit of metal by the current in the deeper tissues. Was there any effect from the treatment other than that on the circulation and nutrition?

DR. BEAVER said he would like to hear further from Dr. Morton regarding the results he had obtained in the treatment of trachoma by metallic electrolysis. So far as they had reported them they appeared to be exceptionally good, as he understood the average duration of treatment had been only about one month.

DR. MORTON replied that the details of most of the cases would be published.

PROFESSOR DOLBEAR said that Dr. Morton had spoken of the value of copper, and Dr. Goelet of the value of zinc in metallic electrolysis; he would suggest that brass, which was an alloy of these two metals, might be as good as either of the metals separately.

DR. MORTON said he had tried brass electrodes, and had found that they gave a prompt deposit of copper. He remembered that Gautier had made allusion to the possible presence of an insoluble salt in the tissues, but he did not recall any absolute demonstration of its existence. In all his experiments in the laboratory with iron, he could not induce the deposit of iron to spread far from the electrode, which was in marked contrast to the behavior of copper. He thought the zinc diffused as well, or possibly even a little better than the copper. A patient had come to his clinic with a tumor of the parotid gland, and it had occurred to him to test metallic electrolysis upon it. A copper needle was plunged into the tumor and the metal freely dissolved off the needle by the current. Before doing this a piece of the tumor had been removed by the trocar. The microscopic examination of this showed it to be a round-celled sarcoma. The metallic electrolysis had not the slightest effect on this sarcomatous growth. In answer to a question by Dr. Putnam as to the action of this form of electrolysis

on cell growth in general, he could only say that he knew of no exact observations on this point. There were certainly no effects on the cell growth in the case of sarcoma just alluded to. He thought there would be an effect on the nutritional processes by the presence in the tissues of a soluble and an insoluble salt of the metal of which the electrode was composed.

THE PRESIDENT said that his experience with metallic electrolysis had been chiefly in treating inflammations of the surface membrane—in endometritis and in gonorrhea—and he thought that in these cases there was a wide field for its action. In almost all the applications of local remedies hitherto made, the albumin of the tissues has been coagulated by these applications, and the bacteria in this way shut off, as it were, from the effect of further applications. On the contrary, by metallic electrolysis one was able to ferret them out and destroy them. He had never found anything so satisfactory for the treatment of gonorrhea, and his assistant had reported that she had obtained remarkably good results with it in endometritis.

## SELECTIONS.

**Contributions to the Theory of Respiration.**—(R. Arnheim, Du Bois-Reymond's Arch. 1894, and Inaugural Dissertation, Berlin, 1894). A digest of this work is stated by the writer as follows: I, the acceptance of a single co-ordinating center is necessary for a satisfactory interpretation of the normal mechanism of respiration; II, the stimulation of Gad's respiratory center in the medulla oblongata alone results in strong activity of the whole process of respiration; III, the changes of respiratory activity which hitherto have been attained, experimentally, from all portions of the central nervous system above the medulla oblongata, do not depend on stimulation of specific centers, but are to be regarded as effects of irritation of the tracts leading to the respiratory center.—*Centralblatt für Physiologie*.

**Contribution to the Study of Gastric Digestion, Under Unusual and Abnormal Conditions.**—(Penzoldt, *Deutsche Archiv. für Klin. Medicin*, Bd. LIII, Hft 3u 4.) The investigations comprise the behavior of hydrochloric and lactic acids, albumin, peptone and sugar. The time of appearance of free hydrochloric acid in health depends, aside from slight variation in the individual, upon the quality and quantity of the food. Very generally food which remains long in the stomach draws out the muriatic acid later than that of short duration. The former commonly contain much albumin, a circumstance which as unprejudiced experiments showed, is responsible for the delay of muriatic acid. The positive reaction of muriatic acid continues longer in the case of food containing little albumin than in that rich in albumin.

The writer ascribes no practically useful importance to the Uffelmann lactic acid reaction. It appears in health after ingestion of the greatest variety of food and drink, either from the beginning to the very end, as it is so variable in its appearance, that it furnishes no positive diagnostic points. Albuminous substances in solution are found in the stomach only in small amount and are altogether absent in the last part of gastric digestion. Peptone reaction follows albumin reaction with only unimportant variations. One can therefore assume, that, as the coagulated albumin begins to dissolve under the influence of the digestive fluids, the formation of peptone also begins. Search for sugar after ingestion of carbohydrates always results negatively, unless the percentage of carbohydrates in the food is over 10, while after food containing large amounts of carbohydrates, sugar can be regularly demonstrated. Comparatively often the sugar reaction disappears early, even long before the stomach is empty. It appears therefore that the prevailing rule for other substances, as peptone, is applicable to sugar, that materials dissolved in water diffuse more quickly out of the stomach than in any medium acting as a solvent in the stomach.—*Centralblatt für innere Medicin*.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

## SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

## MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, APRIL 27, 1895.

## THE COMING MEETING.

Every reader will notice that the program of the papers to be read at the Baltimore meeting is of more than usual interest. The topics are less hackneyed, newer and more suggestive, and the readers include many of the leading medical men of the country. The central location of the meeting should attract a large number of persons who have not been regular attendants.

Notwithstanding the foolish criticism and even condemnation of many persons, the fact has become more prominent than ever, that this ASSOCIATION represents the progress of medical science in America more distinctly than any other organization. In its membership are the teachers and specialists and general practitioners from all over the country. The theorists and dogmatists who arrogate to themselves all there is of science, come in contact with the village and country physician and go away wiser. The teachers and specialists, from the circles of flattery and hero-worship, are astonished at the low estimate their theories sometimes receive. The papers read before admiring friends receive cold criticism from strangers, and scant comment. The surgeon and obstetrician are startled to find the same operations have been made, and sometimes improved on, by men from smaller circles of life. Thus the process of disillusionizing and breaking up the narrow conceptions of truth, and the personal equation of enthusiastic men, give the ASSOCIATION meetings a value that the real student fully appreciates. The credulity and jealousy of narrow circles of professional activity, disappear in the open frank opinions of men from widely separated sections who rise above per-

sonalities. This is the point toward which the scientific work of the ASSOCIATION is rapidly drifting. The reader of papers is judged from a different point of view than at home in his local or State society. His work comes to a relatively higher court, and must rise or fall on its merits alone. Many men overlook this fact, and lose their energies in the natural friction of the organization and management of the ASSOCIATION. They forget this is only a small part of the real work, and the precise rules and plans of working, while essential in many ways, are largely self-limited and self-perpetuated.

The real work—which will live, are the contributions to science, the discoveries of new laws and new phases of old truths. Papers embodying new facts go into the world's literature through these ASSOCIATION meetings more positively than by any other source. The physician who aspires to lead in the march of scientific discovery has an open field here with fewer rivals. He can plead the cause of truth at the bar of the world, and its judgment will be just and clear. Literally, the physician in every section of our country should consider it a rare privilege to become a member and attend the meetings. Every year the topics of medicine are widening and deepening in interest and no man can practice successfully and not keep in personal touch and contact with these great issues. The man who excuses himself from joining the ASSOCIATION because of its politics, its Code, or the possible "rings," is losing his sight and, like a belated traveler, is struggling in the darkness of his own conceit. The man who sneers at and condemns the scientific and literary work of the ASSOCIATION is like a camp follower far in the rear, shouting frantically to the warriors in the front line of their mistakes, and how to conduct the battle. Finally, the man who is ashamed to join the ASSOCIATION and take an active part in its yearly meetings, because it will bring him in contact with persons less trained and of lower caste, is hopelessly stricken with *marasmus*, and needs all the time possible to prepare for heaven.

What shall we say of the *Ego-Maniasts*, whose great erudition and high attainments are not quickly recognized by the ASSOCIATION, in the bestowal of honors and offices? Men who drop out of the ranks disaffected and chagrined, we leave to their fate. The coming meeting should bring to our members an inspiration and wider spirit of devotion and interest to medicine, and personal acquaintance, with the rest of new scenes and new surroundings that will be felt through all the year.

The city of Baltimore offers rare attractions, and the annual pilgrimage of the AMERICAN MEDICAL ASSOCIATION will find here a veritable *Mecca* that will help us all far on the road to the ideal society and ideal meeting.

# DIFFERENTIATION OF SPECIES BY THE BACTERIOLOGISTS.

The Water Committee, of the American Public Health Association, which is organizing a co-operative investigation into the bacteriology of water supplies, is making haste in a slow sure way. We learn that every bacteriologist of note in the United States and Canada, and many of the earnest younger workers, have volunteered in the cause. As a result of a preliminary inquiry into the methods to be adopted, there has been developed the weak point of bacteriologic laboratory work. The subcommittee on the methods of laboratory procedure, after a full consideration of the schemes in use by the various volunteer laboratories, has concluded that it would be unwise to make any effort at the differentiation of species by our present inexact methods. Differentiation is now made with comparative certainty only after studying a dozen or more physiologic characteristics. It is true that under unvarying conditions constant results may be obtained and parallel results under parallel conditions; but it is well known that varieties may arise from divergent conditions in laboratory methods; and hence the necessity for the best scheme of laboratory work in such an investigation as that proposed by the committee. In the opinion of those who have given the matter most consideration, there appears to be little doubt that the present bacteriologic methods fail to inhibit the production of varieties during the course of laboratory study, and that until life histories can be controlled and reasonably normal environment be obtained, there is little hope of a satisfactory differentiation of species. In fact, with increasing knowledge of bacteria along the present lines of investigation, comes increasing difficulty in differentiating.

The committee, therefore, considers that the time has arrived when bacteriologists should come to a halt, and ask themselves what is the cause of this state of affairs and what can be done to remedy it? It proposes to meet these questions boldly. In a circular letter just issued to the bacteriologists interested, it indicates in a general way the errors in the present methods, and calls a meeting in New York city in June, to consider and establish the first principles of the subject and place them on a more substantial foundation. To facilitate discussion and to aid the bacteriologists of the several laboratories in gathering together the evidence which they have at hand, the committee submits twelve questions on which it is assured that the laboratories can bring forward much valuable and hitherto unpublished data. The settlement of these questions will enable the committee to elaborate its scheme of laboratory procedure and permit the co-operative work on the bacteriology of water to progress on lines leading directly to the advancement of bacteriologic knowl-

edge, as well as to the practical sanitary results desired by the American Public Health Association.

The work of this Water Committee carried out in the careful and effective way indicated by the present action of the committee promises to be one of great value. It is a work, however, that should now have been in progress under the supervision of a United States Commission, such as was proposed by the bill introduced into Congress by MR. BARTHOLDT, for the investigation of the pollution of water supplies where such pollution affects or threatens to affect the sanitary condition of the people of more than one State, or better still, under the direction of a Department of Health such as has been urged by the members of the AMERICAN MEDICAL ASSOCIATION.

## PERMANENT CURE OF RHEUMATISM THROUGH MISADVENTURE.

DR. ALAN T. SLOAN reported in the *Edinburgh Medical Journal* for February a very interesting case of successful cardiocentesis. In a hurried attempt to tap the pericardial sac, the right ventricle was entered. The patient, a young woman of 19, was at the time in a very low condition—"practically moribund," as some one has expressed it. The attack was one of acute rheumatism, subsequent to a sharp attack of facial erysipelas; there was the complication, well-nigh fatal, of pericarditis with effusion. In fact, the announcement had been borne to him that the woman had died. DR. SLOAN found her with a pulse too feeble to be counted and with the facial pallor of death. He gave her two subcutaneous injections of ether, whereupon pulse and respiration ceased. In the excitement of the moment the physician took up his aspirator and plunged the needle in the fourth interspace about half an inch to the left of the sternum. Much to his surprise there flowed rapidly into the bottle of the aspirator eight or more ounces of pure blood, showing that the right ventricle of the heart itself had been entered by the needle. The physician felt that all chance for recovery was gone forever. He adds:

"As I was slowly withdrawing the canula, regretfully telling the nurse that it was all over, and to close the patient's eyes, to my surprise the heart made first a feeble irregular movement, then gave a sudden strenuous jump, and finally, like a pendulum regaining its swing or a runner his stride, it started to beat again in the race for life. In moments of intensity it is difficult to estimate time, but I should say fully half a minute had elapsed between the introduction of the needle and the re-starting of the heart-beats. It was an extraordinary sensation to feel the heart beating more and more forcibly against the point of the canula, which was gradually withdrawn so as not to further injure the heart wall. I was standing thus, with my thumb on the puncture made by the needle, when DRs. BRAMWELL and SMITH made their welcome appearance. My uppermost feeling at first was one of regret that I had converted

a patient practically dead into one apparently dying, and sincerely did I lament that she had not been left to pass away in peace, for a most pitiful scene was now enacted for an hour. Occasionally there was given a heartrending shriek; quantities of frothy mucus were half-coughed, half-vomited, and had to be swept out of the mouth with a towel; the blood went ebbing and flowing from the cheeks, which were first ashy gray then purplish in hue; the pupils were dilated to their fullest extent; the running following pulse was quite unaccountable; and the patient had every appearance of one dying asphyxiated."

The cardiocentesis was supplemented by ether subcutaneously injected, the result of which was a maniacal excitement that required opiate treatment. DR. SLOAN continued free stimulation by the mouth with brandy and champagne. The patient's condition improved, so that forty-eight hours after the puncture there was a return to normal temperature and to a pulse of 40. Two months later she was sent away into the country, and four months still later she reported as being restored to perfect health.

There have been other cases of accidental puncture of the heart, when the intended operation was only a paracentesis of the pericardium. One by ROGER, in 1872, the right ventricle of a child was entered, drawing off six ounces of blood; the child was suffering from pericardial effusion. The patient recovered from the effects of the operation, but died five months later from failure of compensation.

DR. SLOAN, in looking up the literature of the subject, found other cases where relief was obtained by cardiocentesis, but his own is the first he was able to refer to as a "permanent cure." He opines that, among other conditions, narcosis from chloroform will be found to be one that will sometimes respond to the aspiration of the heart.

#### THE MANAGEMENT OF PREGNANCY COMPLICATED WITH UTERINE FIBROIDS.

It is generally held by gynecologists that the presence of myomatous masses, either subperitoneal or invading the uterine cavity (especially the latter), favors sterility, and, in the opinion of EMMET and other competent observers, the converse of this proposition is also true, since uterine fibroids are most frequently encountered in unmarried women. In many instances this particular form of hyperplasia is associated with gross lesions of the tubes and ovaries, abnormal conditions of the endometrium, and functional irregularities, which in and of themselves are unfavorable to impregnation, and which are so intolerant of the presence of impregnated ovum that miscarriage frequently occurs. In other cases, the abnormality of these associated organs permits the escape of the ovum into the peritoneal cavity, and abdominal pregnancy is the consequence. Even when gestation proceeds regularly, the development of the uterus must be unsymmetrical, and much pain

and discomfort is occasioned thereby. The growth of the tumor is also likely to be stimulated by the gravid state of the organ, and its rapid enlargement may give rise to pressure symptoms, or produce conditions which cause a more or less serious problem for the consideration of the accoucheur. Finally, the danger to the mother does not terminate with the safe delivery and birth of the infant, for the complication causes the puerperal period to be extended, part of the growth may slough during involution, or gangrenous endometritis may give rise to fatal septicemia. At the last meeting of the Philadelphia Obstetrical Society, DR. ANNA M. FULLERTON reported a case of this kind. It was a primagravida at term, in which labor was complicated with a large fibroid, over the site of which the placenta had been attached. Two hours after a forceps delivery, sudden death occurred, which was attributed to the entrance of air into the uterine sinuses, rendered persistently patulous by the non-contractility of the fibroid tissue.

The uncertainty as to the prognosis concerning the puerperium of a woman suffering with uterine fibroids, was well illustrated by the reports in the same communication of several cases occurring at the Woman's Hospital. The first died as above stated. The second, by constant medical attention, was carried to full term. Labor was greatly protracted owing to the inefficiency of the uterine contractions, and was terminated by the forceps; the child, a large boy, was born asphyxiated and could not be resuscitated. The mother made a good recovery. The third case was especially interesting. It was a farmer's wife, 42 years of age, a primagravida. She had multiple fibroid growths, some in the lower uterine segment, and had been previously advised by two distinguished gynecologists to have a Porro operation performed at term in order to accomplish delivery. Premature rupture of the membranes occurred, however, at the end of the eighth month, and delivery was accomplished by high forceps; the child, a female weighing 2,710 grams, was extracted, and three weeks later mother and child left the hospital in good health. Thirteen months later the patient again presented herself, pregnant and near full term. The tumors had increased in size, so that version had to be performed; the after coming head was caught by a projection from one of the tumors and caused some delay. The child, a large boy, lived only twenty-four hours. Eighteen months later, the patient again applied at the hospital, as before, and was delivered at term, instrumentally, of a girl weighing 3,100 grams. Both mother and child did well. It is most interesting to note that since the last delivery the tumors have markedly decreased in size. A fourth case, primagravida, 29 years of age, aborted at the termination of the sixth month of utero-gestation. After expulsion of the product of conception, it was found that

a large submucous fibroid, about the size of the fetal head, completely filled the uterine cavity. The uterine wall in the part which had covered the ovum, was exceedingly thin. The patient did well until the thirteenth day, when sepsis developed. Hysterectomy was recommended; but consent was not obtained until six days later, when the patient was moribund. General sepsis preceded death and rendered any operation improper. The specimen showed the uterine cavity filled with the large submucous myoma, in a state of degeneration; the endometrium was gangrenous. Death was caused by the sloughing of the fibroid and gangrenous endometritis which had produced septicemia. Other specimens were shown of large uterine fibroids removed by hysterectomy and supra-vaginal amputation. Two presented deep-seated fibroids, which were attended by distressing pressure symptoms, in the removal of which the reporter felt that the supra-pubic method of treating the stump would have been extremely difficult, if not impossible.

The occurrence of pregnancy often constitutes a grave complication of uterine myoma, and the majority of cases so complicated require surgical interference, even when the growths do not encroach upon the area of the superior strait in such a way as to make delivery, *per vias naturales*, an impossibility. The records of the cases cited showed the period of gestation to be one of unusual suffering and discomfort with a constant disposition to premature delivery, rendering protracted rest in bed and the free use of anodynes a necessity. When labor comes on, it begins usually with premature rupture of the membranes, and is characterized by the irregularity, inefficiency and severity of the pains. The paper was followed by an instructive and spirited discussion. DR. B. F. BAER boldly maintained that a woman suffering with fibroid tumors of the uterus ought not to be required to furnish citizens to the State, unless she wished to do so, with a full knowledge of the risk incurred by pregnancy, and if she demanded relief, it was the duty of the surgeon not to withhold that relief, but to proceed to operate, either by removing the uterine appendages or by hysterectomy. He reported a case of a woman who was four and a half months pregnant when the tumor dropped into the pelvis and pushed the uterus up into the abdominal cavity; it could not be replaced and the woman was exceedingly ill. He advised laparotomy and performed a hysterectomy, because the growth appeared sarcomatous, amputating at the supra-vaginal junction. The patient made a good recovery and is still in perfect health, although the operation was done a number of years ago.

DR. CHAS. P. NOBLE spoke of the dangers of peritonitis and sepsis, and said that the mortality of the complication was 50 per cent. When the fibroids are of considerable size, the case should not be left to

nature. He advocated a Porro operation rather than a subsequent hysterectomy; but the cases have to be individualized and can not be treated according to any fixed rule.

DR. M. PRICE favored the Porro operation, and especially directed attention to the mental state attending fibroid tumors. These patients are not only chronic invalids, but many of them are in a nervous condition bordering on insanity. He said that in the last two years he had not operated upon a single one that was not mildly insane.

DR. J. M. BALDY considered that the dangers of the complication had been much exaggerated, and cited cases where all the preparations had been made for a Cæsarean section, but the women had delivered themselves without any difficulty. He would be very loth to act upon the assumption that because a woman has a fibroid she should be denied children, or that her pregnancy might be ended if she wished to have it so. He mentioned a case in which celiotomy had been decided upon for fibroid growths, but for some reason it was not performed; the woman afterward went home and became the mother of a child. He referred to one of DR. FULLERTON'S cases which had been three times delivered and had two living children. He denied that any special nervous conditions or mental disturbance belong to the clinical history of fibroids more than to other instances of pelvic disease. He objected to the extra-peritoneal method of treating the stump, and asserted that hernia was a common result. By dropping the stump, he eliminates a large and important factor in the production of abdominal hernias.

The difference of opinion brought out in the foregoing discussion, serves to illustrate the unsettled state of the subject at the present time. There is much information to be gained as to the direct and indirect causes of fibroid growths of the uterus, and their life history, before anything like a settled rule of practice can be formulated which would apply to a large proportion of the cases. Especially are the difficulties of the problem enhanced by the unusual complication of fibroids with pregnancy. When authorities disagree so widely as to advocate hysterectomy or removal of the uterine appendages, in opposition to those who are perfectly willing to allow the case to proceed to full term without interference or only symptomatic treatment, the plain ordinary everyday practitioner will have to rely upon his own judgment in the management of his cases, feeling assured that whatever course he decides to pursue, he can find good authority to sustain him. As a matter of fact, no general rule can be laid down for the management of these cases of complicated pregnancy. Each case must be treated on its individual merits in the pious spirit in which good old AMBROISE PARÉ practiced surgery, saying to his patients: "*Je te panse, Dieu te guerit.*"

## A GENERAL WITH PRONOUNCED SANITARY IDEAS.

GENERAL DUCHESNE is the chief commander of the French forces that are to be sent to Madagascar. He has recently issued an order or proclamation, showing the profound respect he has of sanitary regulations for troops that are to go to a strange country and climate. In this order he advises with his men to the end that they will observe with strictness all the regulations framed to protect the troops from disease, and especially from malarial disease. On this point he is quoted in the European edition of the *Herald* as saying:

"One of the greatest dangers which the troops will have to encounter will be that of the malarial fever of the country. All possible measures have been taken to combat it, and the GENERAL hopes that the efforts of the sanitary staff will be rendered efficacious by the obedience of the troops to the orders given them. 'The best commanded regiment,' he says, 'will for me be the one in which the fewest cases of illness occur.'

"The most severe orders are given for the humane treatment of the natives. All the persons and property of the friendly Malagasy are to be respected, and the soldiers of the enemy, once they are disarmed, are to be accorded all the rights of civilized warfare and are to be treated with justice and humanity."

AMERICAN MEDICAL EDITORS.—DR. CANFIELD, of the *Maryland Medical Journal*, has completed the arrangements for the editors' banquet. Members of the Editors' Association desiring to attend will please send him their names at once, stating the number of plates they wish reserved.

NOTICE.—All persons attending the meeting who desire to secure return transportation at Baltimore, must obtain a certificate from the agent of the railway at the starting point, showing that they have paid full fare to Baltimore.

## CORRESPONDENCE.

## Pennsylvania and "That Awful Code."

MARIENVILLE, PA., April 15, 1895.

To the Editor:—In the *JOURNAL* of April 13, Dr. Simonton takes one more whack at the Code, and the Philadelphia County Medical Society. That society is amply able to defend itself without my help. But the position of the Philadelphia County Medical Society is the position of the Pennsylvania State Society, and as a member of that body I wish to say a few words in reply to the Doctor and incidentally to all others concerned. I was the wicked fellow who presented the resolutions regarding the *JOURNAL* and the proprietary advertisements at the Philadelphia meeting, 1894. Those resolutions were handed me by some of the most distinguished members of the Society. Dr. E. E. Montgomery, one of the AMERICAN MEDICAL ASSOCIATION Trustees, was, I think, on the floor of the convention at the time. Not a man there but what respected and honored Dr. Montgomery, and our personal or professional relation to him was not called in question. So with the Editor; every member of the Pennsylvania Society who knows of the ability of

Dr. Hamilton has but the highest praise for the successful management of the editorial department of the *JOURNAL*. If this subject must be opened again let it be in that spirit, and undue sarcasm and personalities be completely dropped out of sight. They are uncalled for among gentlemen.

Dr. Simonton says: "The only way to have consistency between the Code and the practice of the profession in regard to patent things in general, is to remove the clause referring to the same, from the Code." That is precisely the argument used by the liquor dealers of New York in regard to Sunday opening of the saloon. They say: "The Sunday law is not enforced nor obeyed; therefore the law should be repealed; and the saloon legally be opened." Any one can see that that principle applied to law would soon be subversive of all law—expediency, not right, be the governing principle. Yield to a wrong, instead of maintaining the right. From my point of view, the editorial in the *JOURNAL* of March 30, "Print the Formula on the Label," covers quite completely the position of the great majority of practitioners. There can be no great objection to even a proprietary combination, if the composition is fully known. It is the name, label or mark, that constitutes the copyright or "patent." The mixture, drug or drugs used can not be tied up for exclusive commercial use. There is no law on earth that can prevent a practitioner from using the formula, compounding it himself, or by prescription at his druggist, if he so chooses to do. Proprietaries of that kind, if used by practitioners under the copyright name, are so used for convenience, and not of necessity. The use of such may possibly be a violation of the letter of the Code, but hardly, I think, of the spirit. Everybody knows that it is the unknown quantity that is objected to in special preparations. No man can intelligently defend the use of a "secret nostrum." The practitioner has a right to know, and in all cases ought to know what his patient is taking. It is tough enough on the laity for us to experiment on them, as we often do, with a known quantity, but to fire into them only a name, so far as our knowledge goes, is tough on the profession, as well as the laity, and is utterly devoid of science.

Dr. Simonton draws comparisons between patented surgical instruments and secret nostrums. In one sense there is no comparison. The practitioner knows what he has got in an instrument; there is no secrecy, no going it blindfold. Let me illustrate this whole subject by a few fancy pictures: Many years ago I sat looking down on President (then Professor) Donald Maclean, screwing down an aortic compressor on a patient. It was not a very fancy affair, if my recollection serves me correctly. He had it made by a blacksmith, and the Doctor had tried it on himself the day before. This instrument successfully controlled the circulation at and beyond the field of operation. Suppose Dr. Maclean had used that instrument then and for all these years on the quiet, and next May appeared before the AMERICAN MEDICAL ASSOCIATION, as its honored President, and said: "Gentlemen, years ago I contrived an instrument that has been successfully used in my hands for such and such purposes. For \$10 I will give you the right to use it, and explain its merits." Suppose he turned from the surgical to the medical, and continued in this way: "At the same time that I thought out this instrument some one blundered, and in consequence a number of students went down with the smallpox. I had unusual opportunities to study out the disease and its treatment, and discovered a remarkable remedy. I am having this put up in convenient form, and you can be supplied at the rate of \$1 per ounce; a small sample will be supplied gratis." Fancy Dr. E. E. Montgomery saying: "Gentlemen, I also, like the President, have made an important discovery; a new operation for the removal of fibroid tumors. Any of you who have patients afflicted in that way who will send them to me will receive 10 per cent. of the amount charged. Operations are private." Fancy our own Dr. Hamilton writing an editorial on the cause of epilepsy, and winding up with: "I have found a most remarkable remedy for this disease, and the members of the AMERICAN MEDICAL ASSOCIATION can have it for \$2 per ounce."

I have used these names because that sort of thing would be so utterly foreign to the nature and the disposition of these gentlemen that misconstruction of the picture is impossible. Fancy the picture, however, and then imagine the result. Yet all this would be just as legitimate as an advertisement of an unknown and unknowable remedy in the ASSOCIATION JOURNAL.

Dr. Simonton speaks of the inconsistency of we sticklers for the Code in taking other medical journals that have the same objectionable advertisements. So we do, but we do not take them for the advertisements, but in spite of the advertisements. We take them on account of valuable reading matter. Because a private publisher uses the brains of an able editor to promote the value of his advertising pages is no reason why the brains of the JOURNAL editor, and the wealth of knowledge he succeeds in getting from his contributors should be used for the same purpose. I am safe in saying that every man of us is proud of the scientific and literary ability displayed in the JOURNAL. Hence we regard it as a shame that its advertising pages should in any sense lower its character and tone. Dr. Simonton's tirade on the inconsistency of the membership is exceedingly weak. Inconsistency of membership or of followers is no argument for the repeal of a standard of faith. The proper thing to do is to lift the erring brother, if possible, to the level of the standard. We can not afford to throw down the fence in this respect; it lowers us to the level of a trade, and finally lands us in a position to say to suffering humanity: "You are sick; you will die without help; we have the secret of your recovery; pay our price and live. If you can not raise the dollars, die." That is the logical outcome of secret proprietary remedies.

From the Pennsylvania point of view, it is a question of right and wrong. In that light, the profession of the Keystone State are not to be moved from their sense of duty, by the calling of names by the gentleman from California. The trouble really seems to hinge on the question of finance. I think that can be easily removed by all of us "whooping it up" for the JOURNAL and making it pay, minus the objectionable advertisements, by a large subscription list. That is a much better way than lowering the columns to the level of the patent medicine almanac. No bickering, gentlemen. "Let all things be done decently and in order."

S. S. TOWLER, M.D.

### Antitoxin.

PHILADELPHIA, April 19, 1895.

To the Editor:—I have had my attention called to your editorial, in the April 13 issue of our valuable JOURNAL, in which you describe "A Fatal Result following a Hypodermic Injection," Behring's antitoxin being the injected remedy. I send you the following notes, trusting that they will be accepted in the spirit in which they are offered. The only comment I have to make, is, that had I known the opus number of the antitoxin used in Brooklyn, I should probably have refused the bottle sent to me.

Friday, April 4, I was called to see Mrs. L. S. W., aged about 30. Her statement was, that on the previous evening she had gone to the theater and on returning home had felt no particular symptoms other than a stiffness in the throat and general malaise. Friday morning she found spots in her throat and at noon had become so depressed as to become alarmed in regard to her condition. The temperature was 101.3-5, respirations 22, and pulse weak, thready and 90. There was excessive dysphagia, the face was slightly flushed, the eyes bright and feverish, and the patient exceedingly languid and anxious. On examining the throat, I found the velum pendulum palati of a dark purplish red, the anterior and posterior half arches being of the same color, saving a small area on the right posterior half arch, which was covered with a suspicious gray membrane about a quarter of an inch in length, and an eighth of an inch in breadth, easily removed by a dossil of cotton on an applicator. The tonsils were apparently normal, the post-pharyngeal wall acutely hyperemic. There was no engorgement of the nasal mucous membranes, though there was a rather too free discharge of a watery character from the nose. Patient was at once placed upon the most vigorous measures, as the patch seemed exceedingly suspicious. At 6 o'clock in the evening of the same day, the spot on the right posterior half arch had entirely disappeared, but the velum and half arches otherwise presented the same appearance as earlier in the day. The patient's face, however, was greatly swollen, hands slightly puffy, and the statement was made that the

urine had been very scanty. The only change in the treatment made, was the addition of strophanthus and digitalis. On the following morning at 8 o'clock there was still no recurrence of the patch on the right side, but there was a patch on the left side exactly simulating that which had disappeared from the right. All of the half arches, moreover, were very much more swollen and the velum was slightly edematous, while the injection of the posterior pharyngeal wall seemed rather to be increased. At noon, sterilized tubes had been secured and inoculation was made. By the kindness of the Polyclinic Hospital Laboratory, the inoculated tube was promptly placed under the most favorable conditions for an early examination. The report from the laboratory was made in a little over twenty-four hours and confirmed in every way the opinion first formed, that the case was one of diphtheria. In the interval, the area covered by the membrane on the left side rapidly increased, the spot first affected on the right side became again involved, and the membrane there rapidly spread until it completely covered the posterior half arches, which were greatly swollen and thickened, and involved the upper third of the anterior half arches on both sides, while a small patch also appeared upon the velum which was now more edematous. To further complicate matters a small circular spot appeared on the posterior pharyngeal wall nearly centrally placed. All this in spite of the most active measures taken to combat the disease. The patient's general condition fortunately rather improved, the temperature fell to very slightly above normal, the pulse somewhat improving in character, and the action of the kidneys greatly improved.

April 8, I obtained through Frank E. Morgan, pharmacist of Philadelphia, a white labeled bottle of Behring's antitoxin solution. The entire contents of the bottle were promptly injected in the left thigh at its inner aspect and middle third, two punctures being made, antiseptic precautions being taken. The patient complained of very little distress, and the fluid was rapidly absorbed. The local treatment, as well as the general treatment, was in no way altered. The change in the appearance of the half arches at the end of twelve hours was simply astonishing. During the late afternoon and evening of the day of the injection, the attendants reported to me that the membranes came away in great masses, and on the morning of April 9, I found nothing but a series of healthy looking ulcerations on the anterior posterior half arches, velum and pharynx. Frequency of the local applications as well as their character were greatly changed, with the idea of simply encouraging rapid healing of the parts. The patient progressed without accident of any kind, and on Friday, April 12, the throat was perfectly clean, and practically normal, barring the slight hyperemia of the velum. On Monday April 15, even this slight hyperemia had disappeared and the patient was discharged after having been subjected to a thorough antiseptic bath from head to foot. At this time, Dr. C. P. Franklin, who had assisted me in the treatment of the case, called my attention to your JOURNAL, and to the fact that the number on the bottle of Behring's solution corresponded with the number of that used in the Brooklyn case, namely, operation 159.

Very sincerely yours, CONRAD BERENS, M.D.

### Cherokee Strip Fossil.

The Remains of an Enormous Extinct Animal Found by a Settler.

HUMBOLDT, ALLEN CO., KAN., April 3, 1895.

To the Editor:—The fossil skeleton of a huge sea animal was recently discovered by a settler in the Cherokee Strip, while searching for driftwood along the banks of the Arkansas River. The beak or bill, was projecting from the sand and on breaking it off, it was found to be bone. This aroused the finder's curiosity to the extent that he set to work to exhume the skeleton. The beak or bill, a few vertebrae, some ribs and propellers were in a fair state of preservation, but the remainder crumbled as soon as exposed to the air.

The discoverer stored his find in a shed, and thought little of its importance. By chance, Henry Patterson heard of it, went to the Strip and purchased it, had a wagon with a cushioned platform built, suitable for the safe transportation of the relic of the antediluvian period, and is now realizing a bonanza from his investment, exhibiting it in the cities and towns of southeastern Kansas. A description of the

remaining bones was sent to the Director of the National Museum at Washington, and the following reply has been received by me:

"The matter is one of great interest from a paleontological point of view, and I have taken the liberty of at once submitting your letter to the Director of the Smithsonian Institution, asking him to write you in regard to the matter and send a qualified paleontologist to investigate the discovery, classify or coin a name for it, and obtain it. The skeleton you speak of is certainly larger than any on record anywhere in the world and it is highly important that it should be preserved in the National Museum."

It has been named by local scientists *monocerosichthysaurus* and *plesiosaurus*. It evidently belongs to neither. By comparisons with descriptions, and from recollections of the larger casts of fossil saurians, the head and vertebrae belong to neither of them. The eye sockets are four feet in diameter, with the supra-orbital notch the same as in the human cranium, with a space of twenty inches between the sockets, making the diameter of the skull nine feet and eight inches, with a small brain cavity comparatively. The vertebrae measures twelve inches each way, and the distance from tip to tip of the transverse processes is forty inches, and resembles those of a mammal rather than a fish. The os hyoides is thirty-eight inches long, a rib thirteen feet eight inches long, circumference thirty-three inches, and two triangular-shaped bones corresponding to right and left, three and one-half by twelve feet, the use of which is conjectured, but supposed to be propellers or fins.

Local scientists who have expressed an opinion, and many have examined it, do not pretend to name it and believe it to belong to no recorded species. It has been variously estimated to have been from sixty to three hundred feet long. I think the latter more nearly correct.

Yours truly,

R. L. PATTERSON, M.D.

### Expert Witnesses.

CHICAGO, ILL., April 20, 1895.

To the Editor:—The following bill is now before the Illinois State Legislature as House Bill 767, and the Committee on Legislation of the State Medical Society asks every member of the profession in the State to assist in its passage by writing at once to his State Senators and Representatives, urging their support of the measure.

D. W. GRAHAM, Chairman.

#### A BILL.

*For an Act to Regulate the Taking of Expert Testimony in Civil and Criminal Proceedings.*

SECTION 1.—Be it enacted by the People of the State of Illinois, represented in the General Assembly, That in any case on a trial in a court of record in this State where expert testimony is to be introduced by both the prosecution and the defense, and also in any other case in the discretion of the court, the presiding judge shall, either of his own motion, or at the request of either party to the suit, subpoena one or more persons who shall be known as court witnesses.

SEC. 2.—Such court witnesses shall be citizens of the State, of known personal probity, and only such as are recognized in the communities where they reside as having special knowledge and experience pertaining to the subjects upon which they are to testify; and if physicians, they shall have been not less than five years in lawful and active practice.

SEC. 3.—The presiding court shall fix the fees of such court witness or witnesses, but in no case shall the fees allowed such court witness exceed fifty (\$50) dollars per day. Such witnesses shall be paid in the manner provided by law for other witnesses, except that in criminal cases the fees of such witnesses shall be paid by the county.

### Wants It Published.

[TELEGRAM.]

PHILADELPHIA, PA., April 23, 1895.

To the Editor:—Philadelphia County Medical Society earnestly requests immediate publication of decision of Judicial Council referred to in Editor's comment on Dr. Roberts' letter.

CHARLES H. THOMAS, Chairman.

ANSWER:—The Chairman was informed that permission would be asked of the Chairman of the Judicial Council to print the decision as requested, and Dr. Brown was accordingly asked by the same mail for such permission.

## ASSOCIATION NEWS.

### The Quimby Amendment.

JERSEY CITY, N. J., April 19, 1895.

To the Editor:—Please find inclosed a letter from Dr. Strong (of Colorado) to me, which I would like very much to have you publish in the JOURNAL. This letter of Dr. Strong's advocates the amendment which I proposed at San Francisco last year. You may remember that I offered to amend the Constitution by striking out the words, "Surgical Instruments" in line 2, clause 5, Article 1. These words should never have been placed in the Constitution in their present relation, as they are disjointed and out of harmony with the rest of the Article. It causes a severe strain of the imagination to find any logical relation between quack or patent medicines and surgical instruments. This amendment I offered last year, I think ought to pass at our coming meeting, as it is in the line of progress of the present age, and in exact justice to the laborer, who is certainly worthy of his hire.

I hope, Mr. Editor, you will see your way clear to advocate the amendment in our valuable JOURNAL.

Yours very truly, I. N. QUIMBY, M.D.

April, 1895.

Dr. I. N. Quimby.

Dear Sir:—Permit an old M.D., who has seen two generations of Doctors of Medicine come and go, to express his gratification upon the resolution offered by you at the last meeting of the AMERICAN MEDICAL ASSOCIATION, to so amend the so-called ethical Code of the profession, as to encourage useful surgical inventions, by permitting members of the profession to avail themselves of the protection the government furnishes to the inventor of any novel and useful instrument or appliance. I think I speak *auctoritate doctissimi Hippocrati* in what I have to say briefly in support of your proposed amendment to our Code.

To those who know my horror of all patent nostrums, of all quacks and quackery, of all self-advertising by medical frauds, I need make no personal defense for my argument. To any one who has witnessed the wonderful achievements of the present century in the domain of useful inventions under the protection and stimulus of patent and copyright laws, inventions that have wrought changes in human existence, human progress and human enjoyment upon the earth, more marked and marvelous than the dream of Utopia or than the imagination portrays of the possible enjoyments permitted to the inhabitants of some far-distant and favored planet, the fact that there still exists among the musty unwritten statutes of the medical profession, a law in effect prohibiting the granting by the government to any member of that profession any protection, any property right, in an original discovery or invention made by him for the benefit of his fellow-men, however useful to the world, and at whatever sacrifice of time, and by whatever exercise of mental gifts; such a law must seem a strange anachronism—a relic of some past age of ignorance, the age of Savonarola or Galileo, when it was a crime to think, to invent, to make any progress that should endanger the hold of superstition upon the human mind. God knows that our profession is a most toilsome, weary, almost slavish vocation—to live to toil, to toil to live; to die generally *de bonis non*, trusting our brief and narrow fame to the kindly memory of surviving neighbors, and our families to the tender mercies of the followers of more lucrative callings.

Can it be that there is a moral wrong in encouraging members of our profession, gifted with inventive power, to discover new and better instruments and appliances to be used in the profession of surgery? In all the most advanced nations a reward is supposed to be offered for every useful invention. This is done by the government protecting the property of the inventor; and this protection is based upon the indisputable moral right of every man to the possession of what he shall create or produce—hence patent and copyright laws. Most of the inventions which have added so much to the well-being of society are the result of the property protection afforded by the patent law. It savors of barbarism to argue that the man who manufactures reapers and steam engines and telegraphs has a better property right than the man who invented them, without which in-

vention they would not be manufactured. While it is not possible to know how many of the most useful inventions are the result of the reward thus offered to the discoverer and producer, we do know that in those countries where no such reward is given, through the protection of the government to the inventor, there has been little progress made from the semi-barbarism of the Dark Ages.

The arguments against giving to the inventors in surgery the protection guaranteed to all other novel and useful inventions, rests upon what might be called a moral theory, which is expressed by saying that it is immoral for a surgeon to accept the reward that all other inventors receive. If so, then it is immoral for the government to create and protect property-rights in inventions, the purpose of which is to relieve physical suffering, while it is in every way proper and commendable that the government should protect the property-right in a locomotive, an incubator or a mouse trap. This conception of the distinction between these two classes of inventions and inventors rests upon the supposed deteriorating influence the giving of such property-right would have upon the character of the inventor, and upon the *morale* of the medical profession—for I insist that my assumption is logical, that if by reason of its bad influence upon the profession, of rewarding the surgeon who by long study, experiment and expense, does invent a successful instrument, he should not be permitted to accept any compensation for his time, labor and expense; then it is wrong for the government to offer such a compensation. It has never been contended that such a reward has had a deteriorating or in any way baneful influence upon the character of the great inventors in the field of the useful arts and in the scientific and literary vocations. In the half century most productive of such inventions, beginning with Morse and coming down to Bell and Edison, it has never been contended that they or Tennyson and Browning and Longfellow and Emerson and Froude and Bancroft and Macaulay and Spencer and a hundred others, venerable, lovable, adored by all good men, and who have done much to elevate and sweeten human life, did anything immoral or anything that cast the thinnest cloud, the adumbration of a shadow upon their glorious lives and their eternal fame by accepting the reward given by the government in the property-right it guaranteed them, in the divine creations they gave to world. Except for that reward, most of the best things in all our literature would have no existence, for these men lived by their pen. Longfellow resigned his professorship at Harvard that he might give us "Evangeline"; Emerson left the old church in Boston, where his unremembered ancestors preached, that he might give us "The Conduct of Life"; Spencer quit the office of an engineer that he might think and evolve and write. Macaulay relinquished a government salary that he might give to posterity his great prose epic of the Stuart dynasty. Except they had assurance that their country would protect her most worthy citizens against a piracy less honorable than Algerine, there had been no "Evangeline," no "Conduct of Life," no Macaulay's "History of England." If there be one field where, above all others, every possible encouragement should be offered by the government and the profession to the devotion of the most intelligent and able minds in the discovery of health-saving, pain-saving appliances, that field is surgery. It is but a remnant of an old and abandoned ethical theory that there can be morally no contract entered into by a professional man that his services shall be paid for, and that the *honorarium* must ever be his entire dependence. We have come upon a practical age, a common sense age, of which one important postulate in its moral code is that every man shall be entitled to just compensation for his services to mankind in whatever field he shall choose to labor. Wishing you all success, I am yours truly,

H. STRONG, M.D.

#### To the Medical Profession.

At the meeting of the AMERICAN MEDICAL ASSOCIATION, held in the city of Washington, in 1884, it was a matter of remark that among the numerous statues of eminent men of National reputation at the National Capital, there was none of any representative of the medical profession, and the suggestion that in Dr. Benjamin Rush there was a man so conspicuously identified with the period of the Revolution as to make him especially entitled to this distinction, was enthusiastically received and a committee appointed by the President, Dr. Austin Flint, to undertake the collec-

tion of the necessary funds. For various reasons, chiefly the difficulty of appealing directly to the widely distributed members of the profession, the enterprise has made slow progress, and statues to men who did not have Rush's pre-eminent claim as a founder of the Republic have been successfully completed by bodies of comparatively very much smaller membership.

The most imposing statues of military heroes at the Capital have cost from \$20,000 to \$50,000, and having in mind the great services rendered by Dr. Rush to his country, the dignity and paramount position among learned bodies of our profession which is to be honored through him, and the many thousands of the intelligent and cultivated citizens of the community who fill its ranks, at least this minimum sum should be collected for the procurement of a fitting memorial. Fifty cents from every member of the profession would suffice to erect the most imposing statue at the Capital; but allowing for the assumed indifference of one entire half of the profession, the committee hoped that subscriptions of \$1 would have been spontaneously and speedily tendered. In this they have been disappointed, and it must now be a matter of pride and duty with every member of the profession, not only to contribute but to assist actively in inducing his colleagues, friends and acquaintances to forward to the committee without further delay, as much as they are able, bearing in mind that this statue is not merely to Benjamin Rush, Doctor in Medicine, however successful as a practitioner, accomplished as a teacher, able as a professor, eloquent as an orator, elegant as a writer, profound as a thinker, exemplary as a citizen, and eminent as an alienist, sanitarian and social reformer, but to the "Father of Scientific Medicine in America," and "the most distinguished physician this country has ever produced." Member of the Continental Congress, signer of the Declaration of Independence, member of the convention which framed the Constitution of the United States, and first Surgeon-General and Physician-General of the Army of the Revolution. Eighty-two years after his death from the epidemic of typhus he was combating, his fame is as resplendent as during the half century of his life, when he was so conspicuous a figure in our national history. No similar train of circumstances has since arisen, nor probably can ever again arise, to enable any other man, however gifted, to acquire the distinction that has made his memory a sacred trust with every medical man of this day and of the future. Let us all, therefore, earnestly unite in fulfilling the obligations of that trust.

THE COMMITTEE.

**Section on Surgery.—Preliminary Program.**—Joseph Ransohoff, Cincinnati, Chairman; R. H. Sayre, New York, Secretary.

TUESDAY AFTERNOON, MAY 7.

1. Address of Chairman, Joseph Ransohoff, Cincinnati Ohio.
2. Cystoscopy, Catheterization of the Ureters and Catheterization of the Kidneys in the Female, by Howard A. Kelly, Baltimore, Md.
3. Aëro-Urethroscopy with the Exhibition of a new Instrument, by W. K. Otis, New York, N. Y.
4. The Value of Urethroscopy in Chronic Urethritis with demonstration of the Nitze-Oberländer, Casper, and Posner Urethroscopes and other Urethral Instruments, by Ferd. C. Valentine, New York, N. Y.
5. Movable Kidney, by Homer Gage, Worcester, Mass.
6. Movable Kidney, by W. E. B. Davis, Birmingham, Ala.
7. The Radical Cure of Hydrocele, by D. C. Hawley, Burlington, Vt.

WEDNESDAY MORNING, MAY 8.

8. Appendicitis, by John B. Deaver, Philadelphia, Pa.
9. Atypical Cases of Appendicitis, by J. B. Emmert, Atlantic, Iowa.
10. Report of One Hundred Cases of Appendicitis, by S. F. Forbes, Toledo, Ohio.
11. Paper, by J. McFadden Gaston, Atlanta, Ga.
12. What Advance has been made in the Surgical Treatment of Hernia, by W. B. DeGarmo, New York, N. Y.

WEDNESDAY AFTERNOON, MAY 8.

13. The Treatment of Malignant Tumors by the Toxins of the Streptococcus of Erysipelas, by Nicholas Senn, Chicago, Ill.
14. Tumors of the Mammary Gland, by W. L. Rodman, Louisville, Ky.

15. Foreign Bodies in the Esophagus, and a Report of five Esophageal Tumors, by A. Vander Veer, Albany, N. Y.
16. Is Total Extirpation of the Rectum ever Justified, by J. M. Matthews, Louisville, Ky.
17. Colotomy vs. Extirpation in Cases of Cancer of the Rectum, by L. H. Adler, Philadelphia, Pa.
18. Branchiogenic Carcinoma, by Charles A. Powers, Denver, Colo.
19. An Original Osteoplastic Operation for the Removal of the large vascular Tumors growing in the Vault of the Naso-Pharynx, Antrum of Highmore, Sphenoid-Maxillary, and Pterygo-Maxillary Fissures, with presentation of Patient, by John A. Wyeth, New York, N. Y.
20. Electrolysis in the Treatment of Sacculated Aneurysm, through Introduced Wire, with Report of a Successful Case, by D. D. Stewart, Philadelphia, Pa.

## THURSDAY MORNING, MAY 9.

21. Scientific Uses of the Surgical Flap, by George Wiley Broome, St. Louis, Mo.
22. Effects of the New Bullet, by J. D. Griffiths, Kansas City, Mo.
23. Asepsis in Private Practice, by Carl Beck, New York, N. Y.
24. The Surgical Technique of Aseptic Wounds, by Henry O. Marcy, Boston, Mass.
25. Flat-Foot—Supra-malleolar Osteotomy with Report of a Case—Photographs and Specimens of Feet of Man, Orang, Baboon, Chimpanzee and Gorilla, by B. Merrill Rickets, Cincinnati, Ohio.

## THURSDAY AFTERNOON, MAY 9.

26. Diagnosis and Treatment of Tumors of the Brain, with a Report of Seven Cases, by Emory Lanphear, St. Louis, Mo.
27. Presentation of a Case of Microcephalus Treated by Extensive Craniotomies, by Ernest Laplace, Philadelphia, Pa.
28. Gall-Stones in the Common Duct and their Surgical Treatment, with remarks on the ball-valve action of floating Choleliths, by Christian Fenger, Chicago, Ill.
29. Skin Grafting after the Method of Thiersch, by J. C. Oliver, Cincinnati, Ohio.
30. Hypertrophy of the Thyroid Gland; an Experimental Study, by Wm. S. Halstead, Baltimore, Md.

## FRIDAY MORNING, MAY 10.

31. A Confusion of Important Terms and some of the Consequences, by R. Harvey Reed, Mansfield, Ohio.
32. Excision, Erosion and Amputation in Joint Disease, by De Forrest Willard, Philadelphia, Pa.
33. Exsection of the Knee-Joint, with Report of a Case of complete Dislocation of the Knee, of nine years' standing, and with especial Reference to Methods of Fixation, by S. F. Forbes, Toledo, Ohio.
34. The Relative Frequency of Joint Tuberculosis, by—

## FRIDAY AFTERNOON, MAY 10.

35. The New Surgical Splinting—Report of Cases Exemplifying it, by E. A. Tracey, Boston, Mass.
36. A Simple Method of Dressing Fractures of the Extremities auxiliary to the Bandage, by John E. Link, Terre Haute, Ind.
37. Deformities following Fractures of the Shafts of Bones, by Thomas H. Manley, New York, N. Y.

**Section on Laryngology and Otology.**—J. F. Fulton, St. Paul, Minn., Chairman; Thos. J. Gallaher, Pittsburg, Pa., Secretary; Executive Committee: E. Fletcher Ingals, Chicago, Ill.; E. L. Shurley, Detroit, Mich.; J. E. Boylan, Cincinnati, Ohio.

## TUESDAY AFTERNOON, MAY 7.

1. Address of Chairman, John F. Fulton, St. Paul, Minn.
2. Electrolysis in Treatment of Intra- and Post-Nasal Fibroid Tumors, by J. F. Schadle, St. Paul, Minn.
3. Deflection of the Nasal Septum, by Eugene S. Talbot, Chicago, Ill.
4. Electro-vibratory Massage of the Turbinate Tissue, by J. Mount Bleyer, New York, N. Y.

## WEDNESDAY MORNING, MAY 8.

5. Electrolysis by a Current Controller for the Reduction of Spurs of the Nasal Septum, by W. E. Casselberry, Chicago, Ill.
6. The Vaseline Spray-producer vs. Surgical Means as a Successful Treatment of Nasal Inflammation, by Thos. F. Rumbold, San Francisco, Cal.

7. Carcinoma of Larynx, with Report of Case, by Norval H. Pierce, Chicago, Ill.
8. The Bleeding Polypus of the Nasal Septum, by W. Freudenthal, New York, N. Y.
9. A Case of Congenital Mucous Polypus of the Nose, with Remarks, by Dunbar Roy, Atlanta, Ga.
10. History of a Case of Recurrent Nasal Fibroma, by Price Brown, Toronto, Can.

## WEDNESDAY AFTERNOON, MAY 8.

11. Operative Treatment of Purulent Disease of the Antrum of Highmore, with Exhibition of New Instruments, by Walter J. Freeman, Philadelphia, Pa.
12. Report of a Case of Caries of the Sphenoid Bone, with Specimen, by Ewing W. Day, Pittsburg, Pa.
13. Further Observations on the Sub-mucous Injection of Creasote in Laryngeal Tuberculosis, by Walter F. Chappell, New York, N. Y.
14. Proper Climate for the Treatment of Consumption with Laryngeal Tubercular Lesions, by John N. MacKenzie, Baltimore, Md.

## THURSDAY MORNING, MAY 9.

15. (a) Breathal Bands, with Demonstration in Situ Nature; (b) Relations of Food to Laryngology, by E. Cutter, New York, N. Y.
16. Laryngology as a Diagnostic Factor in Gynecology, by Carl Seiler, Philadelphia, Pa.
17. Notes on Several Cases of Laryngeal Neuroses, by S. K. Merrick, Baltimore, Md.
18. A Case of Recurrent Fever of Two Years Duration, Cured by the Removal of a Rhinolith; Chemic Analysis of Rhinolith and Nucleus, by W. Sheppegrell, New Orleans, La.
19. New Septum Forceps, by A. J. Erwin, Mansfield, Ohio.

## THURSDAY AFTERNOON, MAY 9.

20. Excision of the Membrana Tympani, Malleus and Incus, in Chronic Purulent Otorrhea, by Chas. H. Burnett, Philadelphia, Pa.
21. Preventable Deafness and its Influence on Career, by Jas. G. H. Nichols, New York, N. Y.
22. What are the Curative Effects of Pneumo- and Phono-Massage on the Middle and Internal Ear, by Louis J. Lautenbach, Philadelphia, Pa.
23. What the Patient Expects and What We Can Do in Chronic Catarrh of the Tympanum or Middle Ear, with Deafness, by Lawrence Turnbull, Philadelphia, Pa.
- (Discussion to be opened by Dr. H. V. Würdemann, Milwaukee, Wis.)
24. Fibrino-plastic Exudates, Etiology and Pathology, with Report of two Cases, including Laboratory Investigation, by D. Braden Kyle, Philadelphia, Pa.
25. A Further Contribution to the Subject of Middle Ear Operations, by S. MacCuen Smith, Philadelphia, Pa.
26. The Importance of Aural Anatomy in Routine Clinical Practice, illustrated with Stereopticon, by B. Alexander Randall, Philadelphia, Pa.
27. Behold, "They Tinker," by J. G. Carpenter, Stanford, Ky.
28. The Surgical Treatment of Chronic Suppurating Otitis Media, by J. H. Bryan, Washington, D. C.

## FRIDAY MORNING, MAY 10.

29. The Upper-Tone Limit in the Normal and Diseased Ear, as Determined by the Galton Whistle, by H. A. Alderton, Brooklyn, N. Y.
30. The Causes of Halitosis or Fetid Breath, by Wm. T. Cathell, Baltimore, Md.
31. Venous Cavernosa of the Nasal Mucous Membrane, by F. E. Boylan, New York, N. Y.
32. A Double Pediculated Naso-Pharyngeal Myxo-Fibroma, by C. W. Richardson, Washington, D. C.

## SOCIETY NEWS.

**Rocky Mountain Medical Association.**—The surviving members of this Association will meet as the guests of Dr. John Morris, Secretary and Treasurer, at the Athenæum Club, Baltimore, on Tuesday evening, May 7, at 6:30 o'clock, P.M.

**Association of Acting Assistant Surgeons of the U. S. Army.**—A special meeting will be held in Baltimore, Md., May 8, during the coming session of the AMERICAN MEDICAL ASSOCIATION. It is earnestly desired that every member of the Association will make an effort to be present, to consider matters of importance. By direction of the President.

W. THORNTON PARKER, M.D., Recorder, A.A.A.S.  
Groveland, Mass.

## BOOK NOTICES.

**Twentieth Century Practice.** An International Encyclopedia of Modern Medical Science. By leading authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D., New York City. In Twenty Volumes. Volume 11. Nutritive Disorders. New York: William Wood & Company. 1895.

The contributors to this volume are: G. S. Dujardin-Beaumont, M.D., of Paris;\* Sir Dyce Duckworth, M.D., etc., of London; Archibald E. Garrod, M.D., etc., of London; Henry M. Lyman, M.D., of Chicago; Thomas J. MacLagan, M.D., etc., of London; Carl H. von Noorden, M.D., Frankfurt-on-the-Main; Max J. Oertel, M.D., Munich.

The topics are: Addison's disease and other diseases of the adrenal bodies; diabetes mellitus; rheumatism; gout; arthritis deformans; diseases of the muscles, and obesity.

The work is well done, as may well be imagined from the names mentioned, but now and then there crops out an eccentricity; for instance, it certainly sounds a little queer to read in von Noorden, page 73, where he writes of the syphilitic theory of diabetes: "More than that, it may be remembered that diabetes was a disease recognized by Greek and Roman physicians, while syphilis is supposed to have been communicated to Europeans by the Indians, after the discovery of America, as if in revenge for their discovery and annihilation." Sprengel, who gave this question much study (*Hist. de Med.*, vol. 11, p. 499 et seq.), asserts that the statement of the American origin of syphilis rests on insufficient proof. In the ancient literature of the Chinese and Japanese, in the writings of Moses, the lament of David, and particularly in the Book of Job may be found such descriptions of the disease, and there is little question that in some form or another it has existed from the earliest times.

The chapter on gout, by Professor Lyman, the only American author in this volume, is complete and interesting. Not only is his style pleasant, but there is breadth of treatment and such thorough knowledge of medical literature displayed as to make this section extremely entertaining.

The volume, as a whole, is quite equal to its predecessor.

**Transactions of the Antiseptic Club.** Reported by ALBERT ABRAMS, a member of the San Francisco medical profession. New York: E. B. Treat. Pp. 206.

This is an alleged funny book, written by a funny man, who seeks to make sport by poking fun at the doctors. It must be confessed that the author sometimes succeeds. The doings of the club are set forth with much humor.

**Charaka Samhita.** Charaka Samhita, translated into English. Published by AVINASH CHANDRA KAVIRATNA. Published at 200 Cornwallis Street, Calcutta.

This is the twelfth fasciculus of the series, the appearance of which we have from time to time chronicled. This fasciculus, which is not less interesting than its predecessors, touches on the very practical topics of wine, water and milk. The student of medical history must receive this book with the keenest interest. The views of the ancient Hindus on water and milk will be read with pleasure.

## NECROLOGY.

GUSTAVUS FRAUENSTEIN, M.D., of New York City, died Feb. 27, 1895. He was an alumnus of the College of Physicians and Surgeons, New York, class of 1868, and a member of the Academy of Medicine, of the County Medical Association, and of the Medico-Legal Society.

AUSTIN SAMUEL CLUTTERBUCK, M.D., died March 28, 1895, at the Memorial Hospital of Morristown, N. J. He was a native of County Tipperary, Ireland, born there Sept. 15, 1864. He came to this country about five years since. His wife was a Dublin lady, Miss Mary Cashin, to whom he was married in Dublin in 1892. He was a licentiate of the Royal College of Surgeons, Ireland, in 1886.

\* Deceased.

MOSES D. VAN PELT, M.D., of New York City, died April 13. He was a graduate of the New York University, in the class of 1835. Until recently he had been in practice at 348 Willis Avenue, but he was temporarily removed to New London, Conn., where death took place suddenly in the eighty-seventh year of his age. He was a member of the Academy of Medicine, the Society for Widows and Orphans of Medical Men, and other organizations. His funeral took place April 16.

WILLIAM HUNTER BIRCKHEAD, M.D., of Newport, R. I., died Friday, April 12, aged 56 years. He was the son of James and Eliza Hunter Birckhead, and allied to several old Rhode Island families. He graduated in arts at Trinity College in 1861, and in medicine from the New York College of Physicians and Surgeons in 1864. He became a member of the resident staff of Bellevue Hospital directly after graduation. This was under competitive examination, and at a time when typhus fever was cutting down interne after interne. He passed through his service with credit and advantage, serving chiefly in the First Medical Division. He was interne at the New York Woman's State Hospital, from 1866 to 1868. In the latter year he became attending physician at the Children's Hospital at Newport. He went abroad in 1871, and spent several months at the clinics in Paris and Vienna. From 1869 to 1879 he served as visiting physician and surgeon at the Newport General Hospital. His specialty, as indicated by the line of careful preparatory study, lay in the direction of the diseases of women and children.

GEORGE FRANK WESTBROOK, M.D., of Brooklyn, died April 12, in his forty-fifth year. He was born in St. Louis, Mo.; graduated from the Long Island College Hospital, first in honor, in the class of fifty-seven, of which he was the youngest member. Five years later he was placed upon the Summer Faculty of that school, teaching anatomy and surgical pathology. He held the position of visiting physician to the Methodist Episcopal and to St. Mary's Hospitals for a number of years, and was a member of the American Climatological and Laryngological Societies, of the New York Academy of Medicine, and of most of the Brooklyn medical societies. He was a frequent contributor to medical literature, and had devised, among other things, a daring method of drawing blood from the overcharged right side of the heart with a fine hollow needle, in otherwise hopeless cases of pneumonia. His health broke down four years ago, but he was entirely his vigorous self again for some months last summer, at the end of his long vacation. For the past year he had been writing extensively for a system of therapeutics, and at his death was engaged on a large work on medical diagnosis. He was an independent thinker and a close student, and studied his patients as individuals, with a thoroughness few men use. His patients were his warm personal friends, and he had the power to develop strong personal affection in his students and colleagues through his kindness, his heartiness and his honesty, as well as a wide faith in his quiet power. The cause of his death was pneumonia, the duration of the attack being about four days. He leaves a widow and one child.

GEORGE CUPPLES, M.D., of San Antonio, Texas, April 20.—E. J. Lawton, M.D., of Rome, N. Y., April 19, aged 60.—A. C. Nixon, M.D., of Hanover, Ohio, April 17, aged 72.—John P. Wall, M.D., of Tampa, Fla., April 18.—H. W. Foster, M.D., of Pittsburg, April 14, aged 23.—D. L. Starr, M.D., of Pittsburg, April 13, aged 83.

## PUBLIC HEALTH.

**Demography of France.**—The report of the French Department of Statistics for 1893 has been published in the *Journal Officiel*, from which it appears that there were registered 287,294 marriages, 6,184 divorces, 874,672 births and 867,526 deaths. This is a slight improvement over the figures for 1892, being 18,825 more births and 8,362 less deaths, so that in place of a loss of 20,041 inhabitants for the country in 1892 there is a slight net increase of 7,146. While the total number of marriages shows a falling off of 3,025; it is nevertheless, superior to the mean of 280,000 for the decimal period between 1881-90. The increase in the number of marriages—since the large population immediately following the year 1870-71 has arrived at a marriageable age—renders it probable that the low birth rate for the last twenty

years, on account of the large number of young men killed in battle, will begin to rise again. This seems to be indicated by the increase in 1893 after a three years deficit. Although as above stated, the total number of marriages was 3,025 less than in 1892, yet in 28 departments the number of marriages increased. The number of marriages corresponds to 7.56 per cent. of the population. As usual, the mountain departments, which furnish the most adult emigrants, have the smallest number of marriages—5.6 in the Lower Pyrenees, 6 in the Upper Pyrenees, 6.3 in Corsica and Savoy, etc. The largest proportion, 9.3 per cent., is in the Seine department. The divorces, which numbered 5,772 in 1892, increased to 6,184 in 1893. The northern departments and Paris had the largest number—110 and 171 respectively per 100,000 families. Births, which had been lowered since 1890, increased by 1882, 5, with a total of 874,672, of which 446,957 were boys and 427,715 girls. It may be stated that the increase was general, for it prevailed in 71 departments and only decreased in 16. The general birth rate was 22.9 per 1,000, varying from 14.9 in Gers to 33.5 in Finisterre. Natural births increased in 1893 to 76,562—the highest ever observed, being a proportion of 8.8 per 100. These were most frequent in the departments in the north and northwest; in the Seine department the proportion was 24.3 per 100. Deaths amounted to 867,256, of which number 449,682 were men and 417,844 women, the rate being 22.8 per 1,000. While the mortality in 1893 was 8,362 less than the year preceding, it is still too high. The mortality in France rules the increase or diminution of the population, and the attention of municipalities and hygienists should be directed toward it, especially in the first years of life.<sup>1</sup>

**"Kissing the Book."**—The Legislature of Pennsylvania has decreed that the oath on the Bible shall be dispensed with. The Governor of the State has indicated that he will approve of the enactments to that end. While it has always been at the option of the swearing citizen to "affirm" or to take the oath, the average person has not known of this alternative, and has done as directed when told to "kiss the book." This latter has the tradition and awe of the ages of court procedures behind it, but the multitude can not fail to recognize the change as a modern reform. The silent work of the theory of the germ production of disease has undermined the time-honored process that has been winked at and tacitly continued by the police and other magistrates. These latter are not all of them "posted" on the properties of a kiss-moistened leather-covered book to hold and to propagate the bacilli of disease, and the presumption is that not a few of the Pennsylvania Dogberries will regard the amending act as a blow against the defenses of justice. To such, no doubt the removal from their desks of the dirty greasy Bible will appear as a misfortune and an ill-advised innovation. To our bacteriologists and sanitarians, however, it will stand as a mile-post on the road of progress.

**Diphtheria Antitoxin.**—A circular of the Massachusetts State Board of Health.

The investigations of Behring and Roux with reference to the value of serum-therapy in the treatment of diphtheria, and the later experience of its use in diminishing the mortality from this disease, are widely known and fully understood. The State Board of Health, in accordance with its organic purpose as defined in the statutes, having in view the "interests of health and life among the citizens of the Commonwealth," and recognizing the value to the people of any agent which will measurably prevent the ravages of a disease capable of destroying more than a thousand of lives annually in Massachusetts, and of causing suffering which can not be expressed numerically, has in this State prepared a supply of antitoxin, for the benefit, primarily, of such communities as find it difficult or impracticable, for any reason, to supply themselves with the new agent from reliable sources. Great care has been exercised, in the preparation of this supply, to fulfill the most exacting technical requirements for obtaining a pure and trustworthy product, and the tests of its strength have shown satisfactory results. The board does not propose to offer it for sale, but its gratuitous distribution will be under strict conditions, designed to prevent abuse and waste, and to obtain the most beneficial fruits. Each bottle is marked with a number and the

date of the preparation of its contents. No antitoxin will be issued except upon a pledge that a full statement of the observed effects of its use will be returned to the board at the termination of the case. In all cases possible, a bacterial diagnosis will be insisted upon. The board desires to emphasize the importance of using such appliances only as are adapted to the proper administration of the remedy, of remembering that experience has demonstrated that antitoxin is most useful in the earliest stages of a diphtheritic attack, and of realizing that trained medical skill is required to administer it successfully. A blank form for the report and a detailed statement of instructions as to methods will accompany each bottle of the antitoxin serum. For the needs of persons living within twenty-five miles of Boston, it will be required, for the present, that personal application at the office of the board shall be made by the attending physician in the diphtheria case, or by some person authorized by him. For the convenience of more distant parts of the State, local agencies at public hospitals or municipal health offices will probably be established by the board in accessible centers. The office of the board (Room 141, State House Extension), is open each week day, except Saturday, from 9 A.M. to 5 P.M., and on Saturday from 9 A.M. to 2 P.M. SAMUEL W. ABBOTT, Secretary.

State House, Boston, March 25, 1895.

**Health Reports.**—Sanitary reports to the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Iowa: Des Moines, April 17, 1 case.  
Missouri: St. Louis, April 6 to 13, 21 cases and 2 deaths.  
Ohio: Cincinnati, March 28 to April 18, 31 cases and 2 deaths; Cleveland, April 6 to 13, 1 case; Coal City, March 28 to April 18, 1 case. (Removed to hospital at Cincinnati); Columbus, April 13 to 20, 1 case; Wellington, March 28 to April 13, 2 cases.  
Pennsylvania: Chester, April 13 to 20, 1 case of varioloid; Philadelphia, April 6 to 13, 11 cases.

SMALLPOX—FOREIGN.

Argentine Republic: Buenos Ayres, January 1 to 31, 7 deaths.  
England: Birmingham, March 31 to April 6, 1 case; Derby, March 31 to April 6, 1 death; Liverpool, March 31 to April 6, 3 cases; London, March 31 to April 6, 53 cases.  
Germany: Prague, March 23 to 30, 2 cases.  
Gibraltar: April 1 to 7, 2 cases.  
Holland: Amsterdam, March 31 to April 6, 1 case, 1 death; Rotterdam, March 31 to April 6, 3 cases, 2 deaths.  
Mexico: Nogales, April 6 to 13, 2 cases, 2 deaths.  
Russia: Batoum, March 26 to April 2, 10 cases, 2 deaths; Odessa, March 23 to 30, 3 cases, 2 deaths; St. Petersburg, March 23 to 30, 7 cases, 1 death.  
Scotland: Edinburgh, March 31 to April 6, 8 cases, 1 death; Glasgow, March 31 to April 6, 45 cases, 2 deaths.  
Switzerland: Basle, March 16 to 23, 7 cases.

YELLOW FEVER—FOREIGN.

Italy: Bologna, March 31 to April 6, 1 case.  
Mexico: Vera Cruz, April 4 to 11, 1 death.

CHOLERA—FOREIGN.

Argentine Republic: Buenos Ayres, January 1 to 31, 27 deaths.  
Japan: Hiroshima, March 29, 1 case; Moji Naval Station, March 19, 18 cases and 10 deaths. March 22, 1 death.

YOKOHAMA, JAPAN, March 29, 1895.

Sir:—I have the honor to inclose copies of official dispatches with regard to what appears to have been a slight outbreak of cholera, at the station of Moji, southern Japan. The very active measures taken by the Japanese authorities seem to have been successful in stamping out the disease, as no new cases have occurred since the 19th or 20th inst. I may say that, in the military and naval posts, not only are the regular quarantine and sanitary laws applied, but they are backed by a specially stringent code administered under the War and Navy Departments. The Japanese Government fully recognizes the imminent danger of the importation of disease with returning soldiers, sailors, and above all, through the large bodies of coolies which are employed in army transportation, and have taken such measures as seem best adapted to meet the emergency.

The danger is, undoubtedly, a grave one. Cholera is, practically, endemic; in more than one Chinese city all the maladies which so often follow in the train of war and famine are of possible occurrence, and the distance between the

<sup>1</sup> Bulletin Medical.

Chinese and Japanese coasts is covered in but a very few days.

I regret to say that already, through the native authorities, I have official information of the appearance of several cases of the plague at Hongkong, within the past week. The recurrence of this disease with the advancing spring has been confidently expected by all familiar with the history and laws of this malady, especially in view of the so far, very perfunctory action of the Government of Hongkong. \*

\* \* \* \* I am, Sir, Very respectfully,  
(Signed) STUART ELDRIDGE, M.D.,  
Sanitary Inspector, U. S. M-H. S.  
ENCLOSURES.

FUKUOKA, March 18.  
At the town of Moji, Fukuoka Ken, cases of acute vomiting and purging have appeared since the 8th inst., to the number of eighteen, with ten deaths. Careful clinical and post-mortem examinations by two able physicians, who declare the disease to be cholera. The first case had been in communication with a vessel that came from the China coast.

(Signed) GOVERNOR of Fukuoka Ken.  
FUKUOKA, March 20.  
There is no new case since yesterday, and disinfection and preventive measures are fully carried out.

(Signed) GOVERNOR of Fukuoka Ken.  
FUKUOKA, March 21.  
To-day every house has been suspected and disinfected, and there is no new case.

(Signed) ARITA, Chief of Police, Fukuoka Ken.  
FUKUOKA, March 22.  
There is no new case since 20th inst. One death yesterday, five remain under treatment.

(Signed) ARITA, Chief of Police, Fukuoka.  
HIROSHIMA, March 29.  
Yesterday cholera attacked a coolie who has worked on the transport ships at Ujina. Forty men who had been living with him, and thirty more who had communicated, are isolated and under observation.

(Signed) GOVERNOR of Hiroshima Ken.

## MISCELLANY.

**Change of Address.**—Dr. Jas. T. Jelks, to 218 Central Avenue, Hot Springs, Ark.

**The Samaritan Hospital for Women**, Montreal, was opened by Her Excellency, the Countess of Aberdeen, Jan. 17, 1895.

**Dr. Bayard Holmes.**—Dr. Bayard Holmes, has been re-appointed as Secretary of the College of Physicians and Surgeons of Chicago.

**New York Ophthalmic and Aural Institute.**—This institution has been named in the will of the late Mary Putnam Bull, formerly of Tarrytown, N. Y., to receive the sum of \$2,000, to be applied to the sustentation account.

**Professor Schnabel.**—Dr. Stellwag (von Corion) late the Professor of Ophthalmology in the Faculty of Medicine, University of Vienna, has been retired on account of age. Dr. Schnabel, of Prague has been appointed to the vacancy.

**Many Indorsements.**—The Chicago Medical Society, the Chicago Gynecological Society and the Chicago Academy of Medicine have passed resolutions requesting Mayor Swift to retain Dr. A. R. Reynolds as Health Commissioner of Chicago. The judgment of the JOURNAL as expressed last week on this subject is thus seen to be the voice of the whole profession. Will the Mayor heed it?

**The Code Question.**—The Code question will not down. The premature publication of a hasty resolution passed at a poorly attended meeting of the Cleveland Medical Society has resulted in a renewal of the agitation of this subject throughout the medical press in such a way that it will force itself upon the attention of the AMERICAN MEDICAL ASSOCIATION meeting at Baltimore. It is to be hoped that this question will soon be settled, so that the valuable time of the ASSOCIATION may be better occupied in the discussion of scientific papers.—*Cleveland Medical Gazette.*

**The Royal College of Physicians.**—The Royal College of Physicians of London held an extraordinary comitia for the purpose of electing a President. Sir J. Russell Reynolds was re-elected. In his annual address, President Reynolds stated that "the committee appointed to carry out the decennial revision of the nomenclature of diseases had practically completed their labors, had passed the volume in proof a few days since, and it was about to be issued by the Queen's printers."

**Vermiform Appendix in Hernias.**—Kraft reports seven cases of hernia, in three of which the appendix alone was herniated, in the other four there was a loss of intestine in addition. After searching the literature and comparing his cases the author concludes that if the appendix is neither perforated or gangrenous it is to be reduced; in case of perforation or gangrene, resection of the appendix is indicated. The intestine if present in the hernia, whether gangrenous or not, is to be uncovered for inspection, as in all cases of gangrenous intestinal hernias.<sup>1</sup>

**Instance of Longevity.**—I was born in 1793, and since then I have never been ill a single minute," is the statement of Dr. de Bossy, the oldest of French physicians, who is still in active practice at Havre. He has never followed any special diet, and is opposed to anything of the sort. He rises at 7, summer and winter, and as soon as he is dressed starts on his rounds, usually on foot. He has drank coffee all his life, has no objection to a glass of bitters, and tobacco is "a poison which he regularly absorbs." He attributes his longevity to moderation in all things. His father lived to be 108. Dr. de Bossy took his degree in 1818, then went to England, and later to India, where he practiced medicine, and returned to Havre, where he has since been at work, sixty-four years ago. He has two sons, the elder 68 years old.—*Tribune.*

**Legislation for the Prevention of Blindness in Missouri.**—Several weeks ago a bill was introduced into each house of the Missouri Legislature, which contains in substance the same provisions as already exist in the laws relating to this subject in New York, Maine, Rhode Island, Minnesota, Ohio and Maryland. In Missouri the bill has passed both houses with little or no opposition; but still awaits the signature of the Governor. It would be a real misfortune to the State if he failed to adopt the advanced policy which has actuated lawmakers in so many States already, and is interesting the more intelligent leaders in still other parts of the Union. The Committee of the AMERICAN MEDICAL ASSOCIATION will make its report at the meeting in May, and we surely hope that the Governor of Missouri will not deprive his State of the privilege of being counted among those adopting this enlightened policy of the prevention of blindness from ophthalmia neonatorum.

**Treatment of Strangulated Hernias.**—Chalita has in the last eight years treated ninety cases of strangulated hernia in the Jewish Hospital at Kieff. If the general state of the patient is good, taxis should be tried under narcosis. It was successful in thirty-three cases after the strangulation had lasted from one to five days. If symptoms of peritonitis or collapse are present, immediate operation is necessary. The exact method to be used varies with the case. The author performed twenty herniotomies with 15 per cent. mortality; twenty-nine operations on hernias already gangrenous with resection of the intestine had 3 per cent. of deaths; three intestinal fistulas were successfully treated by the enterotome and one stercoral fistula was sutured. Herniotomy was followed in seven cases by the radical operation which is always indicated according to this author if the intestine is healthy.<sup>2</sup>

**New Hemostatic.**—Hederich recommends a new hemostatic, ferripyrin. This substance is a definite combination of perchlorid of iron and of antipyrin in the form of a reddish-orange powder, readily soluble in cold water. It has some appreciable advantages over the perchlorid. It is not

## LECTURES.

### LECTURES ON INTRACRANIAL SURGERY.

#### VII—BRAIN TUMOR AND ITS SURGICAL TREATMENT.

BY EMORY LANPHEAR, M.D., PH.D.

ST. LOUIS, MO.

Resuming description of cases of tumor of the brain and its envelopes, upon which I have operated, I next wish to relate the history of an

*Osteoma—Operation—Recovery.*—W. L. W., of Fairport, N. Y., aged 28 years, I first saw in June, 1889. His family history was good and his health excellent until 1884, when he had syphilis. In June, 1887, he fell and injured the right side of his head, from which he was unconscious for several hours. Soon afterward he began to have headache with a tender spot just in front of the right parietal eminence; then there was a change in his disposition; he became irascible, shiftless and vulgar, began drinking heavily and taking morphin for the head pain. Some time during 1888 he had a "stroke of paralysis" after a hard debauch, the left hand and arm remaining paralyzed for some weeks; motion gradually returned under large doses of iodid of potassium. During the latter part of May, 1889, he had intense headache over the motor region of the right side of the head, accompanied by vomiting and much difficulty in walking. He again drank heavily and on June 1 had a second paralytic attack. He was found unconscious; completely paralyzed upon the left side, and with aphasia, agraphia and word blindness, as was noted June 2 after he regained consciousness. His entire vocabulary consisted of "God damn fool" and "morph," the latter being a request for morphin uttered in a piteous tone. For several days convulsive movements of the paralyzed side were noticed, leading to the conclusion that the lesion was superficial. He was placed in my care June 5 and remained under observation for a number of weeks, the aphasia continuing unimproved, only a slight degree of motion returning in the leg and none in the arm, in spite of the most vigorous antisymphilitic treatment and the use of electricity. The frequency and severity of the convulsions of the affected side became less and finally this symptom disappeared. The "morphin habit" was cured. His general condition improved to a remarkable degree and he became fat on immense doses of iodid of potassium. On August 1 he could read the newspapers and novels for hours, was feeling well and decided to return home; the paralysis and aphasia continued the same, so I accompanied him to his home in New York. He came to me again Feb. 5, 1891, anxious to be trephined, as he had heard me say that was the only chance of relief. The paralysis of left arm was still complete, but a little motion was found in the leg and he could walk with the aid of a crutch. Some command of language had returned, but speech was child-like in character. General health fair.

At 10 A.M., Feb. 22, 1891, with the assistance of Drs. W. S. Allen and John Puntton, I opened the skull with chisel and mallet and attempted to enlarge the opening with bone forceps, but the tissue was so hard at the point of attack that a very strong pair broke and it was necessary to complete the operation by carefully chiseling away the bone, bit by bit. A tumor of the bone was found, extending from near the middle line at a point just over the Rolandic fissure downward and forward over the motor area for a distance of nearly three inches. A cross-section presented the appearance of the accompanying illustration.

The external table was not at all raised or thickened but the vitreous plate was very thick and excessively hard. After removing the bone, I opened the dura and inspected the brain. The cortical substance of the arm center and the posterior lower part of the frontal convolutions appeared

blanched—"atrophied," as Dr. Puntton expressed it—and he further expressed the opinion that the speech center was, in this patient, in the right hemisphere. I then explored the subcortical tissue and white substance to the internal capsule at two points, but found no sign of old hemorrhage. I closed the two wounds in the dura with fine catgut, checked oozing with hot water, inserted a drainage tube and closed the scalp at the end of one hour and forty minutes.

At 6 P.M., he was in fine shape. He spoke much better than before the operation, said he could move his leg with greater ease and expressed himself as very hopeful of permanent benefit.

My entry for February 24 says: "Eats and sleeps well. No fever. Says he feels much better than before the operation. He can completely flex leg and thigh of left side, which was impossible before. Got out of bed and walked around ward last evening! And to-day went to water closet for bowels to move. Passes urine with far less straining than any time since paralysis began."

The drainage tube was removed February 26 and permanent dressings applied. The wound was in good condition and at the next inspection (March 2) was found healed by primary union. March 14 he was walking without a cane, the paralysis of the leg having almost entirely disappeared and the arm much better—some movement in the fingers being perceptible. He then said: "My bad headache is gone with all my other bad feelings; things look clearer and more natural than in years." There was little more improvement during his stay in the hospital. He was discharged April 27 in perfect health—paralysis much better than previously and mental condition decidedly better.

Section of osteoma; actual thickness.

He returned to the hospital on June 1, in good condition, but under the influence of whisky and with but a few dollars in money—hence very much discouraged. As he was not ill he was discharged from the hospital June 2. He committed suicide at Leavenworth, Kan., June 3. The post-mortem examination was made by Dr. M. S. Thomas, who recorded that: Rigor mortis was complete and firm on the right side, but not so complete on the left. Left arm one inch less in diameter than right, and left thigh one and one-half inches less than right. A somewhat circular opening was found on the right side of the head covered by scalp with large C-shaped cicatrix. Calvarium removed having in it a roundish opening (loss of bone)  $2 \times 3\frac{1}{2}$  inches. There was no evidence of suppuration; there was an adhesion of the dura mater at the edge of the bone and a thin ligamentous filling-in of the opening already begun. *The brain seemed to be perfectly healthy everywhere.* The conclusion, made before the jury, was that a recent surgical operation had been performed on the head and that he came to his death from morphin taken hypodermically, etc.

It is to be regretted that this patient killed himself so soon after recovery from the operation, as it would have been instructive to note the amount of improvement that might follow removal of such a long-continued pressure. Is it possible that complete regeneration would have eventually been noted? I think it hardly probable. But in spite of this, I was well satisfied, indeed, with the decided change wrought by the operation. If I had had the courage of my convictions, and operated when he first came under my

care, I believe a cure might have been effected. Three other points are worthy of notice:

1. The fact that the patient stood the prolonged operation so well. Had I not spent much time in trying to cut the bone with forceps, and had I omitted the useless exploration of the brain, I might have completed my work inside of an hour; yet in spite of the severity of the operation, the long-continued anesthesia, and the use of the mallet and chisel, there was practically no "shock." I account for this chiefly by reason of complete hemostasis—there was not more than four to six ounces of blood lost altogether.

2. The rapidity of convalescence. As noted in the history, this man insisted upon getting up inside of twenty-four hours, and never could be kept in bed except at night after the second day. Yet no harm resulted, so far as we could determine.

3. Aphasia with right-sided lesion. Since the physician who made the autopsy is positive in his assertion that there was no lesion discoverable in the brain, we must conclude that the paralysis was due to the pressure of the tumor, and the aphasia also to the same cause; if this assumption be correct, the speech-center must have been located upon the right side. He was, he asserted, ambidextrous, but wrote with the right (paralyzed) hand. He learned to write his name with his left, after convalescence from the last comatose condition.

Another case, of especial interest on account of the favorable result, as well as the localizing symptoms, was the following:

*Subcortical Tumor—Operation—Recovery.*—A. C., stockman from Montana, consulted me Dec. 18, 1890. He was a Swede, 41 years of age, married fifteen years. His family history was good, and health excellent until 1876, when, in Southern Kansas, he had what the doctor called "malarial fever," from which he was in bed many weeks, and did not completely recover for more than a year; never had been as well since as he was before this attack. He suffered from heat stroke in 1878, after long exposure to the hot sun of the prairie; he was very sick for several hours, and convalesced slowly, being in bed fully two weeks. Afterward he was subject to "sick headache," *i. e.*, attacks of pain upon the top and left side of his head, accompanied by great prostration, vertigo, and vomiting of mucus; these were promptly relieved by a brisk cathartic. The last attack occurred in March, 1889, but a dull pain in the left side of the head began soon after, and had been pretty constant since. In September or October he began to have trouble with his right arm and side of face—slight spasmodic contraction, with muscular weakness. The paroxysms had increased in frequency and severity, until the spasmodic contraction of the muscles was so great as to be exceedingly painful; and he was positive that the uniform course was this: spasmodic contraction of muscles of the right side of the face and head, especially marked in the eyelid, quickly involving the hand, then the arm and forearm, and neck, causing violent spasm of the flexor muscles of the arm, forearm and fingers; the convulsion always begins with pain and severe contraction of the muscles about the outer side of the right eye and the temporal region; during the attack the head and eyes turn violently to the right, and he gasps for breath; he becomes totally aphasic for a period of ten to fifteen minutes after each spell, but there is never any loss of consciousness. He was very positive as to the constancy of this course. The attacks appeared two or three times a week, but though increasing in number, more than two weeks elapsed between the last two before the examination. He felt very much exhausted for some hours after more recent convulsions, and a numbness persisted in the hand and arm for several hours. Examination showed no trouble with the urine—specific gravity 1026—or with the organs of the chest and abdomen. The retine were pale—no evidence of choked disc.

While there was no history and no signs of syphilis, I put him upon appropriate treatment for gummy tumor for some weeks, and kept him under careful observation. This was the only alternative, as he would not consent to operation. He had only two attacks in January, 1891—one on the 15th

and the other on the 27th. January 30, I suspended the antisyphilitic remedies, and ordered Charcot's "black mixture," bromid of sodium, pepsin and charcoal in glycerin and water. He disappeared.

April 7 he again consulted me, expressing himself as anxious for operation, as the convulsions returned early in February, and were getting very hard and numerous—sometimes two in one day. Two or three general epileptic seizures had occurred within two weeks, the pain in the head was becoming unbearable, and his general health failing. He had an attack of minor degree in my office, tallying well with his previous description; urine passed about an hour later showed specific gravity of 1032, with sugar in considerable quantity, but no albumin or phosphates. I prescribed 6 drops of the fluid extract of *syzygium jambolanum* thrice daily, and a tonic of arsenic and bitters. Under this he improved in his general condition, the glycosuria disappeared, and he was in such good shape that I sent him to the hospital April 24.

Operation April 26, assisted by Drs. Monks and Maxson. On removing a portion of bone 2x3 inches over the speech and arm centers, the dura presented an unduly tense feeling, but did not protrude into the opening, nor present any evidence of abnormal growth upon it—so it was incised in a horse-shoe flap and turned back. The brain showed through the pia as slightly reddened beyond the normal; closer inspection showed what appeared to be a tumor, and palpation revealed a hardness that ought not to be present, situated just at the lower end of and anterior to the fissure of Rolando. I therefore attempted to raise the pia, but finding that too much traction wounded vessels of considerable size, I carefully tied vessels running in the direction of the affected area by slender catgut, and then cut through the somewhat elevated cortical tissue—very gently, for fear of wounding tissues which should escape injury. A small tumor, of pinkish-white color, was thus disclosed, and examination showed that it did not present firm attachments;

Diagram showing location of tumor.

that is, it did not infiltrate surrounding structures. Attempts at enucleation, however, proved futile, and I was therefore compelled to remove the tumor by means of a sharp spoon, thus preventing microscopic examination—much to my regret. The tumor was the size of a very large cherry, and was quite vascular; the surrounding tissue, too, was engorged, and consequently hemorrhage was very brisk. However, I succeeded in curetting away all diseased tissue, and then tried to arrest the bleeding with hot compresses; this failing, I was compelled to pack the cavity with iodoform gauze, quite lightly, and close the dura and scalp around the protruding gauze. No attempt to replace bone was made. Duration, fifty minutes.

The patient was put to bed in bad shape—shock profound and pulse weak and thready. Eight hours after operation the patient appeared to be conscious but could not speak; the right arm was paralyzed, and so much difficulty in swallowing was present that all medicine was given hypodermically and stimulants and food per rectum. His pulse was 140 and weak and his temperature 102 degrees, and I feared much for his safety. During the night his condition improved somewhat, but the paralysis continued all the next day and the difficulty in swallowing persisted.

April 28, the condition was much the same at 8 A.M., pulse 148, temperature 102.5 degrees. He had slept some during the night. The dressings were removed and the iodoform gauze drainage carefully withdrawn. Very little oozing

had taken place and no bleeding followed removal of the packing—so the separated margins of scalp were pressed together and permanent dressings applied. This day he improved rapidly so that in the evening he murmured, "Water, water," and drank greedily with but little difficulty, Evening temperature 100 degrees.

April 29, speech returned to a remarkable degree and voluntary movements of the right side were noticeable. From this time on, convalescence was satisfactory in every respect, the aphasia and paralysis totally vanishing. He had but one Jacksonian attack—very slight—which was noted the day before his discharge, May 19. He appeared to be in excellent health. I saw him again on June 5, and again upon July 9 at each of which visits he declared himself perfectly cured. He promised to keep me informed of future progress, but I never saw or heard more from him.

It is peculiarly unfortunate that the character of this subcortical growth could not be ascertained. It had the peculiar appearance of glioma. The absence of implication of surrounding tissues would lead one to believe it was not malignant, though the rapidity of growth (October to April) would indicate that such might be its nature. It is possible that it may have begun much earlier than the date set, but from the marked increase in number and intensity of the paroxysms in the few weeks prior to operation, I believe the tumor must have been growing with a deal of rapidity.

I can not leave the subject of tumors without giving a short description of my other fatal case:

*Cyst of the Arachnoid—Operation—Death.*—Wm. K., from the Indian Territory, was brought to me by Dr. O. W. Krueger, Jan. 8, 1892. The previous history was not obtainable to my satisfaction, but it seems that he was as intelligent as other boys until about the age of 14 years when he began to have epileptic convulsions of the right side, followed by temporary aphasia. The spasms finally became general, partaking of all the characteristics of *grand mal* including the mental deterioration. Finally, partial paralysis of the right side gradually made its appearance accompanied by difficulty in remembering names and other nouns. As the epilepsy increased in severity this paralytic influence deepened until at last he was completely paralyzed in the right upper extremity, the use of the lower was so greatly impaired as to prevent walking, and language became totally obliterated. He frequently read the papers for a little while at a time and seemed to understand much of what was said, though his intelligence was evidently greatly impaired.

Owing to the fairly clear, though not wholly satisfactory evidence, that the convulsions invariably began in the right hand, then spread until the whole body was involved, and also to the existence of the aphasia, I had him sent to the hospital where I opened the skull, assisted by Drs. Krueger and Maxson. Upon opening the dura a cyst of the arachnoid was found, much larger than a hen's egg, lying over the speech and arm centers. This I tried to remove entire, in doing which I fear I exerted too much pressure upon the brain, for the patient ceased breathing (although no chloroform had been given for several minutes) and only revived by long-continued artificial respiration. I hastily cut away the cyst and closed the dura, only stopping to notice that the speech and arm centers were of a very pale hue wholly unlike the surrounding cortical tissue, and that the impress of the tumor upon the brain did not disappear with removal of the cause. While closing the dura, another suspension of respiratory efforts was noted and again artificial respiration had to be instituted. The wound was quickly closed and dressed and the patient placed in bed as hastily as possible, when every possible means to combat shock was employed—to no avail; he died within a very short time. An autopsy was not obtainable.

What the result might have been in this interesting case can be only a matter of surmise; but from the long continuance of the pressure upon the two important centers, I feel sure that the prospect of complete recovery was not good, but probably the mental condition would have vastly improved had he lived.

While the direct cause of this patient's death is

somewhat of a mystery to me, I can not but feel that I did wrong in attempting to secure a beautiful pathologic specimen—it would have been better surgery to simply open and drain the cyst, which was evidently not malignant—but I did not know at the time that such treatment would yield satisfactory results. Since then I have treated one other simple cystic tumor by such means and with perfect results. My seventh and eighth cases were in young patients, of tubercular character, and gave no points of especial interest save the satisfactory and speedy recoveries. They will be reported in due time in some medical publication.

Based upon this experience, and a careful study of the subject of brain tumor, I give you these

#### RULES FOR TREPHINING.

*When to Operate*—1. A headache, which becomes more and more intense, persisting for weeks, with later exacerbations of an agonizing character, followed by stupor, disturbed sleep, loss of memory and optic neuritis, is a strong indication of tumor in the frontal region and warrants exploratory trephining; upon both sides, if necessary, in order to find it.

2. A tumor of the frontal convolutions, as indicated by the signs just enumerated, may encroach upon the motor zone so as after a time to give rise to some focal symptoms (spasm or paresis); in which case the trephine should be applied just in front of the coronal suture of the side opposite to the motor symptoms.

3. Tumors of the mid-brain may present as evidence of their existence, a tendency to stupor, occasional irritability and childishness with disturbances of the motor area (Jacksonian epilepsy) and papillitis—generally choked disc; craniotomy over the upper Rolandic region is the proper treatment.

4. Disturbances of the muscular sense, with the usual mental impairment and with choked disc, are sufficient to justify examination of the supra-marginal gyrus.

5. When the symptom-group consists of word-blindness and lateral hemianopsia, with moderate loss of power in one-half of the body, the skull should be opened over the region of the inferior parietal lobule and angular gyrus.

6. Homonymous hemianopsia, not dependent upon other cause than tumor, indicates operation over the cuneus and first occipital convolution.

7. When hemianesthesia accompanies lateral homonymous hemianopsia, the lesion lies between the cuneus and the primary optic centers; trephining should be done so as to expose the point where the occipital, parietal and temporal lobes meet.

8. A tumor giving word-deafness as its most prominent symptom, may be reached by opening the skull on the left side in the region of the posterior part of the first and the upper posterior part of the second temporal convolutions.

*When not to Operate*—1. It is useless to attempt operation in cases of undoubted brain tumor, when the growths are situated in the corpus callosum and the optico-striate region.

2. It is questionable whether or not operation is advisable in cases in which the usual symptoms of tumor are accompanied by disturbances of speech as the only "localizing" sign; the lesion will probably be found to be not near the speech center, as one would infer, but affecting the pons, medulla and the point of origin of the cranial nerves.

3. Nystagmus, either unilateral or double, permanent or temporary, complicated by paralysis of the motor nerves of one or both eyes, constitutes a barrier to operation as the trouble is unquestionably basal.

4. When nystagmus appears in the history of a case suspected to be tumor, associated with epileptic attacks or hemiplegia, the tumor may be upon the convexity just behind the fissure of Sylvius, but so often this is *not* the location that operation can not be advised.

### FORCIBLE ALVEOLAR EXPANSION IN THE TREATMENT OF CONSUMPTION.

BY W. H. WEAVER, M.D.

CHICAGO.

In the search for a cure for this most deadly of diseases, it seems that experimentation has been directed entirely toward the discovery of some wonderful specific, (to the exclusion of the simple truths of physics, anatomy, physiology and pathology). All the energies of the profession and of manufacturing chemists have been spent in the vain hope of finding this specific,—to their great pecuniary advantage.

Now that the specific hunters in Germany and elsewhere have about lost themselves in the mazes of organic chemistry, it might be profitable to work over some old knowledge in these branches, which has been at a discount for some time past.

A classic paper on this subject was read in the Philadelphia County Medical Society, by Dr. Thos. J. Mays, and appeared in the *New York Medical Journal*, March 10, 1888, entitled, "Apex Expansion vs. Pure Air in Pulmonary Consumption." Concerning the cure of consumption, the following conclusions were drawn: "That the question of curing the disease did not depend on the purity or freshness of the air, nor upon the number of bacilli the atmosphere might contain, nor upon the amount of oxygen which might be introduced into the body—for these were all secondary considerations; but it was simply a mechanical question,—a question as to the best mode of expanding the lungs, and especially the apices of round-shouldered and flat-chested patients, of removing the infiltrated products already existing, and of enhancing the constitutional resistance."

It may be said that the tubercle bacillus inhabits the lung tissue as an infection of tissue already damaged by hereditary malformation, sluggish circulation, or the extension of catarrhal bronchiolitis, plugging the alveoli. The bacillus aids in the extension of the infiltration, the same as other infectious germs poison tissues which have been injured. Dr. Prudden has recently shown how the presence of the germs of suppuration hastens the destructive processes by cavity formation in a previously tubercular lung, when the two processes of tuberculosis and suppuration run a simultaneous course.

Has it never occurred to these "specific" hunters that if a remedy should be found which would kill the bacilli *in situ* in the tubercularized tissue, the alveolar plug of gelatinous matter would still remain as a spore—containing a source of irritation; and as soon as the remedy should be withdrawn, the disease would break out anew? "An empty house is better than a bad tenant." The treatment which

does not drain the alveoli, empty them, and restore ventilation, will never be of very great benefit. In the case of mastitis, where the galactiferous glands and tubes are plugged, their drainage is accomplished by nursing, the tubes are emptied and healthy conditions and functions restored.

Minute anatomy and physiology tell us that the alveolar wall is composed largely of elastic tissue, which aids in the expulsion of air when released by the relaxation of the muscles of inspiration. Air pressure will dilate them the same as any elastic vessel, and as soon as the pressure is removed, this elasticity together with the expiratory muscles, forces out the contained air as well as any fluid which happens to be in them. The alveolar plugs are composed of a thick gelatinous and albuminous fluid. These plugs irritate the lung tissue and become the foci for extended infection. The elasticity of the alveolar walls is retained until the inflammatory process has progressed to the destructive stage, then there is necrosis of portions of the consolidated area. If we succeed in an effort to empty the air cells of this plug, the cell walls retain their continuity and a return to health is inevitable. In surgery, drainage of wounds and cavities probably septic, is absolutely necessary to the healing process. Physiologic drainage of the alveolar cavities is just as certain to give good results. This drainage is a simple mechanical procedure possible of accomplishment by every patient. The gelatinous plugs with their bacilli are carried out by the air current into the larger tubes and expectorated. These principles have been the basis for the method I have pursued in the treatment of the cases in this report.

The method was described in an article which appeared in the *New York Medical Journal* Oct. 13, 1894, entitled, "Forcible Apex Expansion in Incipient Phthisis." It consists not only in full breathing, which has been recommended in various ways, but after a full inspiration, the breath is held for a moment by closing the glottis—*just as the breath is held while straining at stool*, so as to increase the air pressure in the lungs. It should produce a ballooning of the chest and consequently of the air cells themselves. The effect is increased if, during the holding of the breath, the lower chest is compressed with the hands, which action forces the air into the upper chest where the consolidation usually is, and at the same time lifting the weight of the arms and shoulders off the chest. After a time the inspirations become much fuller and a higher tension develops. If the patient is weak, the breath should not be held more than two to five seconds; with increasing strength the time may be extended a few seconds at each effort. But the length of time the air is held is not important, the tension which can be developed being the end desired. These efforts may be continued regularly every two hours during the day, before arising in the morning and after retiring at night, as there is probably more air inspired in the recumbent position, because the weight of the arms is removed from the chest. Holding the breath has been mentioned by some writers, but usually the patient is directed to exhale slowly at the same time. It is thus performed without closure of the glottis, by simple exertion of the inspiratory muscles. No tension is developed and it is consequently only an inspiratory exercise, and fails to accomplish the end desired because it does not forcibly dilate the alveoli. The

direction to hold the breath is very indefinite without specifying the manner in which it must be held. An inhaler may be used with some antiseptic and soothing inhalant and to stimulate interest in the treatment. The patient may be told to inhale deeply so as to get the medicament well into the lung tissue. It will require some practice in order to get the best results, but an ambitious patient will pick it up very quickly. The immediate result will be an increased amount of oxygen in the blood, a strengthened heart's action, and a facilitated expectoration, which alone gives relief. In young persons the elasticity and capacity of the chest will be permanently increased, the progress of the disease inhibited and immunity from future attacks almost insured.

The treatment by differentiation of air has a similar effect on the lungs, but in order to be of much benefit more than one treatment a day would be required.

The contra-indications are hemorrhage, and for a few days after it has stopped, the pulmonary gymnastics should be suspended. But, I think in my cases the treatment has had rather a beneficial effect on the hemorrhagic tendency, probably because the pressure tends to close up the bleeding vessels. A weak right heart and possibly any heart disease would require great care in introducing even a slight and temporary obstruction to the pulmonary circulation. However, such cases are quite rare and will not greatly interfere with the general adoption of the method.

The existence of cavities seems to be no contra-indication, as in one case not in this report the whole left lung seemed to have been reduced to cavities and the treatment has been followed with success for over a year. Pleurisy, if quite general, will be aggravated by the chest movements for a time until the consolidation begins to disappear. To overcome the muscular atrophy about the chest any gymnastic exercises will be of benefit. At the same time, proper medication should be employed in order to increase the chances and rapidity of the recovery, improve nutrition, stimulate blood formation, or in any way improve the condition of the patient. For high fever, I believe bathing is the proper antipyretic.

The rapidity of the improvement will depend greatly on the extent of the consolidation, and the capability of the patient to understand the necessity, and the zest with which he pursues the treatment. A frivolous person will not put forth enough energy to take a full breath and hold it, or even test the treatment,—as in one of my cases I could not get the patient once to take a full breath; although the case is reported, I do not consider that the treatment was ever tried twice in this case.

The histories of the following cases demonstrated the efficacy of the treatment as well as the accuracy of the principles which lead up to it:

*Case 1.*—Mrs. M. J., aged 35, no tubercular family history. During the winter of 1892-93 had a severe attack of bronchitis and in March, 1893, asthma was added to her torture. In May and June there was improvement in the asthma, but the expectoration was profuse. There was then afternoon fever, rapid pulse, night sweating, and emaciation—pleuritic pains and soreness through the right upper chest. Examination of the sputum revealed the presence of tubercle bacilli. Physical examination showed a marked area of dullness posteriorly over the right apex, by the slight dullness, bronchial respiration, bronchophony and rales. The treatment included an inhaler using a eucalyptol mixture, tonics when they seemed to be of any benefit, a trip to a

farm in the country, and the pulmonary gymnastics or breathing exercises, holding the breath as described and other physical exercises with Indian clubs, the exerciser, or any means which tend to develop the muscular system. In December, 1893, physical examination showed that the area of consolidation had entirely disappeared, and there had been steady general improvement during the whole treatment. At present she is practically proof against the tubercle bacillus.

*Case 2.*—Miss H. M., aged 28, stenographer; mother died of consumption. Began treatment August 9, 1893, for hay fever, which was readily cured by the removal of some post-nasal hypertrophy. Had been feverish and losing weight and strength, sweating at night, and coughing of late. Physical examination showed a marked consolidation at the right apex. As the expectoration was scanty, no microscopic examination was made. Treatment much the same as in Case 1, save that the patient had only a short vacation of two weeks from work. As she was ambitious to get well she pursued the treatment with great determination. In this case I was able to examine the patient frequently enough to observe the rapidity with which the infiltration disappeared so that I was able to foretell almost the exact time it would take to remove it and pronounce her practically cured. Feb. 1, 1894, the lung had entirely cleared and the symptoms of the trouble had disappeared. Her weight had increased to normal and to this day she is well.

*Case 3.*—Mr. J. A., aged 32, student, whose family history reveals the fact that four sisters have died of consumption. He came to me Nov. 1, 1893, feeling very miserable, was coughing, losing weight, sweating at night, afternoon fever; temperature 100 to 102, pulse 96 to 110. Physical examination disclosed a considerable area of consolidation over upper half of left apex. Microscopic examination showed numerous bacilli. Treatment brought about a complete recovery by the latter part of March, 1894. At this writing he assures me that of all the colds he has had this winter not one has extended below the larynx, when previously every cold he had descended to the chest, and that he is entirely well and weighs 148 pounds.

*Case 4.*—R. D., aged 26, began treatment Dec. 23, 1893, having hypertrophic rhinitis and catarrhal laryngitis. Weakness, emaciation and fever induced me to examine the lungs when the evidences of consolidation of the apex of the left lung were unmistakable. As one reputable physician had previously diagnosed the case one of tubercular laryngitis, I felt considerably interested in the case. Treatment was followed by complete recovery, in the month of April, 1894, and his health remains good to this day.

*Case 5.*—Mr. H. P., aged 49, carrier, came to me Feb. 18, 1894, having cough with profuse expectoration, pain in the right side, emaciation, having lost twelve pounds, losing rapidly the past month. Physical examination showed an area of consolidation in the lower anterior portion of the middle lobe of the right side. Patient often had an evening temperature as high as 102.5 degrees F. Pulse rapid, especially during fever. Bacilli numerous in the sputum. Treatment brought about a slow but steady recovery and all signs of the local lesion had disappeared in November, 1894. This patient was almost constantly out of doors, and if fresh air will prevent tubercular consumption, he should never have developed the disease.

*Case 6.*—Miss B. A., aged 18, began treatment March 23, 1894, having had hemoptysis, the two nights previous. Has coughed for some months, fever every day, mostly in the afternoon, ranging from 101 to 103 F., emaciation and night sweating. Examination showed consolidated left apex. Treatment included ergot for hemorrhagic tendency and tonics. Pulmonary exercise was neglected by this patient. I endeavored in every way to induce her to continue the practice, but failed, and in the course of two months she passed from my charge and has since died.

*Case 7.*—Mr. C. H. M., aged 38, came to me April 12, 1894. Had had attacks of stomach disorders for several years, emaciation, slight cough, scanty expectoration, containing a few scattering bacilli. Physical examination showed infiltration of the apex of the right lung. Temperature 100 F., pulse 90 to 100. Treatment removed every trace of the trouble in eight months.

*Case 8.*—Miss L., age 24, came April 18, 1894, having a temperature of 101, pulse 90, hypertrophic rhinitis, slight cough, and scanty expectoration, emaciation and profound prostration, tired all the time, weight 95 pounds. Physical examination showed increased expiratory murmur over right apex, also voice and whisper sounds, with dullness on percussion. Treatment was energetically carried out and in

August every sign of the lung infiltration had disappeared, her general condition improved and weight increased to 115 pounds.

*Case 9.*—Miss E. P., aged 25, came to me May 7, 1894, having severe pain and tenderness in back of upper dorsal region. Had been failing rapidly during the winter, with irritating cough and scanty expectoration, afternoon fever and rapid pulse. Physical examination found consolidated right apex, with some pleuritic friction, sounds, soreness, and pain in that region, chest expansion twenty-six to twenty-seven inches. Treatment removed the area of consolidation by November.

*Case 10.*—Mr. C. J. D., aged 24, consulted me June 26, 1894, for relief from fever, night sweating, loss of weight and strength, and cough. Weight 112 pounds. Upon examination I found dry râles, and the usual evidences of a consolidated right apex extending as low down as the third rib. Temperature 101 to 102, afternoons. Pulse ranging about 100. Microscopic examination showed numerous tubercle bacilli in the sputum. Treatment at once instituted and followed out vigorously, brought a complete cure. August 29 there were no râles or other signs of the consolidation discoverable; and later in the fall he recovered all his lost weight.

*Case 11.*—Miss L. K., aged 29, consulted me July 20, 1894, for supposed nasal catarrh, and a generally run down condition, weight 99 pounds. She had afternoon fever, cough, but scanty expectoration. Upon examination, the usual signs of consolidation of the left apex were found. In two months treatment she had gained ten pounds, and in one month more the lung tissue had resumed a normal condition.

*Case 12.*—M. H., aged 23, book-keeper, consulted me Feb. 27, 1895 for an irritating cough and general weakness, following a recent attack of la grippe. Patient was never in good flesh, being tall, thin and pale, recently losing strength, and what little superfluous flesh he had. Had afternoon fever, pain in the left upper chest, expectoration mostly in the morning, which on microscopic examination was found to contain numerous bacilli. Examination of the chest showed moist râles, slight dullness and bronchial breathing over left apex, anteriorly and posteriorly. Treatment at present writing is giving the best results, having reduced the afternoon fever from 101 to 99, increasing the weight by six pounds and restoring almost his normal strength and feeling.

*Case 13.*—R. W., aged 30, merchant, seen in consultation with Dr. A. Salter at Lena, Ill., April 15, 1893. For six months or more previously had night sweating and emaciation, weight 128 pounds, temperature, morning 95.51 to 97, and every afternoon as high as 102 F.; pulse 90 to 100. Examination disclosed a complete consolidation of the right upper lobe. Treatment including tonics and 10 minim doses of creosote three times daily, alternating with hypophosphitis. Breathing exercise was begun and improvement began in two weeks, which was steady until January 1894, when there were no signs remaining of the lung infiltration. His weight at present is 150 pounds, and he is an active business man.

*Case 14.*—Mrs. H., aged 33, was also seen with Dr. Salter, Feb. 4, 1894. Had been taking various remedies for a year or more for a cough and other pulmonary symptoms, complaining mostly of pain in the shoulders and upper chest. Upon examination the right apex was consolidated, and slight infiltration of the left apex. While before treatment the patient was so poorly that she could do no housework, she has recovered sufficiently to do her own housework, gaining twelve pounds in weight, and two inches in chest expansion. There are at present no signs of the old consolidation.

*Case 15.*—Mr. J. H., aged 28, book-keeper. This man was seen in consultation with Dr. P. L. Anderson of this city, June 1, 1894, having in all about fifteen hemorrhages; night sweats; temperature 102 F.; pulse 120; profound weakness; barely able to do light work. Sleep greatly interrupted by coughing and a great amount of expectoration. Microscopic examination showed very large numbers of bacilli. Patient had attacks of asthmatic coughing, and hay fever symptoms during September. Upon examination of the chest the lower lobe of the left lung was found consolidated, also the apex of the same side. This patient has not been seen for some months, but at my request he came in for examination. He says that he had considered himself cured, having increased in strength so as to be at work every day—weight increased from 128 to 145 pounds. He coughs some, however, and expectorates most in the morning. He says that he has

not practiced the pulmonary gymnastics for some time. Upon examination pulse and temperature are normal, as also were the respirations. The left chest was found somewhat contracted, and the respiratory capacity diminished. Percussion note same on both sides; auscultation revealed no bronchial breathing or voice sounds, or anything that would indicate consolidation. There were, however, a few fine and some coarse mucous râles, with diminished vesicular murmur over the left lower lobe and the upper half of the left upper lobe. Also there were heard some faint pleuritic friction sounds over the left apex. This case is interesting, in that it shows how extensive and how rapid the tubercular processes may be, and still be entirely checked and recovery take place in a comparatively short time by this system of treatment. The condition of the left lung at the present time may be considered as practically restored; although there still remain catarrhal processes in the bronchial tubes, some few scattering plugged alveoli and others which are entirely collapsed or obliterated and replaced by cicatricial tissue which interferes with its normal elasticity and respiratory capacity.

*Case 16.*—Mrs. B. P., age 33. This case was also seen in consultation with Dr. Anderson some time in March, 1893. A diagnosis of pulmonary consumption was made in September, 1892, by Dr. Anderson and confirmed by Dr. Wm. E. Quine of this city, and the patient advised to go immediately to Albuquerque, N. M. Patient remained in New Mexico about four weeks during which time she suffered greatly from pleuritic pain, becoming extremely weak, night sweating, chills and fever, temperature at times as high as 103 degrees F., lost all appetite and it was with the greatest difficulty that she stood a stage ride of thirty miles to the nearest railroad to Colorado Springs. During a stay of two weeks in Colorado Springs she was much worse than in New Mexico. Believing there was no hope for recovery she came home. Soon after her return to Chicago, she began to improve and was able to come to the office for consultation. I made an examination of the chest and found the usual evidences of tubercular deposit in the apex of the right lung, accompanied with the most extensive pleuritic friction sounds I think anybody ever heard over the upper half of the chest. Deep breathing caused a great deal of pain in the chest. Pain was the most distressing symptom in the case, while there was also a great deal of emaciation, anemia and night sweating. Weight 110 pounds. She was cautiously trained in the pulmonary gymnastics and light physical exercise. Notwithstanding the pleurisy and the pain caused by the taking of full breaths, this patient continued the pulmonary gymnastics until every sign of the consolidation had disappeared, which was in September, 1894. There is still considerable pleuritic pain but nothing compared to what she had previously suffered.

It would seem from the results in this case that chronic pleurisy is no important contra-indication, and it must be decided by the results after a cautious trial in each case. Some patients with sufficient practice may be able to hold the breath at a tolerably high tension, enough to inflate the alveoli without much chest motion.

To recapitulate the cases:

Recoveries 13; improved and under treatment 2, dead 1.

I consider that of the sixteen, fifteen are consecutive recoveries, the remaining one not having followed out the treatment.

Phthisis is curable by the application of well-known mechanical principles, viz., the inflation of an elastic air sac with elastic air, which gradually during expiration expels the semi-solid or fluid contents. It is necessary in order to get the quickest and best results, to begin treatment while the sac wall is still intact and elastic, for when it is once broken down and cavity formation has begun, then the area must heal by cicatrix.

In the matter of prevention of consumption, the same process of alveolar ventilation is necessary and absolutely certain of results. During the years of physical growth and development the puny, flat-chested, round-shouldered children should be taught proper methods of breathing, together with occasional forcible expansion of the chest. While the

bony chest wall is still elastic it should be developed. After the age of 25, the capacity for chest development is necessarily limited.

126 State Street.

# SERUM THERAPY IN PULMONARY TUBERCULOSIS, WITH AN EXPLANATION OF SECONDARY SYMPTOMS FOLLOWING THE ADMINISTRATION OF ANTITOXIN.

BY CHARLES WILSON INGRAHAM, M.D.

BINGHAMTON, N. Y.

Much has been written in regard to certain unpleasant and untoward symptoms attending the administration of antitoxin in cases of diphtheria. There has been a disposition on the part of physicians to attribute these symptoms to some peculiarity of antitoxin after its introduction into the system of diphtheritic patients. Some regard them as due to secondary septic infection. I believe, however, that I shall be able to prove substantially that these identical symptoms will follow the administration of pure serum with the same certainty and severity as they follow the use of antitoxin. I base this statement upon the manifestations which I have observed to follow the administration of serum from the blood of the mule in cases of laryngeal and pulmonary tuberculosis.

The most constant and unpleasant symptom following the administration of mule serum is the intense eruption which covers every portion of the body and gives rise to terrible itching. The eruption is of a bright red appearance and if scratched too persistently will assume for a short time the form of a large "water blister" which appears suddenly. It remains for a greater or less length of time, usually a few hours, and then disappears as suddenly as it made its appearance. Accompanying the onset of the eruption there is marked anorexia and depression.

Another symptom which fortunately does not appear as frequently as the eruption, but which is very much more painful and serious, is the "neuralgic pains" which are most apt to occur in the neighborhood of the point of injection, but which may occur in a remote part of the body. The pains are usually of so severe a nature as to deprive the patient of sleep, even after an opiate has been administered. I have known them to continue for twenty-one days without interruption, although this is an unusually long period.

In my experiments with serum, I used that obtained from the mule, because of the recognized immunity of that animal from tuberculosis.

In December, 1894, I obtained a full grown, healthy mule, and after he had by good care and feeding been brought to an excellent standard of vitality, tapped the jugular vein and drew therefrom a quart of blood. The most careful antiseptic precautions were observed in the operation. The hair was shaved for a radius of several inches around the site of the intended incision. The skin was then cleansed and finally washed with pure alcohol. The lancet used, was procured especially for the purpose and was thoroughly antiseptic. The blood was received in a glass jar, especially prepared. (I mention these precautions to show that the results finally obtained from the serum were not due to any infection consequent upon its preparation.) The blood was allowed to

stand twenty-four hours, and the serum was then drawn off and filtered through antiseptic filter paper. This work was done in a cold room to protect against putrefaction changes. After the first filtering the serum was allowed to stand a few hours, when it was observed to have thrown down a slight sediment. After a second filtering no sediment was observed. An effort was made to add a 5 per cent. solution of carbolic acid, but by every method tried, a precipitate was thrown down and the serum became cloudy. The serum used was, therefore, the pure article, without additions of any description. The serum was preserved in antiseptically prepared vials, which were hermetically sealed and only opened as immediately needed. Syringe used was an ordinary one drachm, rubber piston, and when not in use was kept filled with alcohol. The greatest care was observed in cleansing it, following its use. Gold needles were used.

The first case treated was one of tubercular laryngitis, with secondary pulmonary involvement. Cough was severe. Expectoration profuse and purulent.

Dec. 31, 1894. First injection was administered in the lower part of the thigh. The amount given was 1 drachm. On the second day dose was increased to 2 drachms. Cough seemed to improve at once and expectoration diminished slightly. No other appreciable improvement either in symptoms or local condition. The site of injection gave rise to no swelling or inflammation, more than that attended by needle-puncture, and I was congratulating myself upon the ease with which these treatments could be administered when my hopes were severely crushed. On about the tenth day the patient complained of severe pain shooting up and down the thigh. Examination of the limb gave no indication of inflammation. Next day, however, the limb was swollen, the pain was worse and patient was put to bed. Pain was so severe that a hypodermic injection of morphin was given and poultices were applied over the painful area, but with little relief. Patient slept but little for nearly a week, at the end of which time the pain was a little better, but it did not disappear until the twenty-first day from its beginning. The limb was at no time much swollen and there was scarcely any rise of temperature, except during the period of eruption which appeared soon after the pain set in and continued about four days. Subsequent injections, after the pain had entirely disappeared, did not give rise to any further pain or eruption. Patient received a total of between forty and fifty injections of the serum of 1 drachm each, but at the end of the treatment no improvement whatever, either in symptoms or physical signs, had taken place.

At first I was inclined to believe that the pain and eruption were due to something peculiar in my supply of serum, or perhaps also to some extent due to the condition of the patient, but seeing in current medical literature reports of cases of diphtheria treated with antitoxin which gave rise to symptoms so closely identified with mine, I concluded that the origin of these unpleasant manifestations was to be found in the primary serum.

In eight cases of pulmonary tuberculosis, subsequently treated with the serum injections, the eruption was a typical attending symptom, while the pain did not occur unless a large amount of serum had been injected in a short period of time. From

my study of and experience with these cases, I came to the conclusion that a very minute quantity of serum would give rise to eruption as intense and in every way identical with the eruption following the administration of large quantities; that the pain was not a constant after-effect, only appearing when a large amount of serum had been given; and that with proper precautions, and by not throwing too much serum into the system in a short period, the pain would be wholly obviated. The eruption would appear in from three to ten days following the first injection. In one case where only one injection was given, the eruption was very severe. The eruption would usually continue for a period of from three to seven days and would be accompanied with a marked rise of temperature, which in a few instances reached 104 degrees. I have noticed that the eruption was more severe in cases of pulmonary tuberculosis of an acute nature. The most remarkable phenomena or results following the eruption is a total disappearance of fever for a period of from twenty-four to forty-eight hours and a temporary improvement in general symptoms. I am sorry to say that this marked relief following the eruption is only temporary. I have never seen any results of a permanent nature. Cases of acute tuberculosis in whom the temperature ranged from 103 to 104 degrees daily, previous to the injections, would be entirely relieved from the fever for a period of from two to three days, only to be followed, however, by its return to its former height and persistence, nor would there be any appreciable improvement of symptoms or physical signs of a permanent nature.

Although the injections were administered for a sufficient length of time for them to manifest any curative properties, I am obliged to record that I did not in any individual case see an improvement that would warrant a continuance of the treatment.

I do not, however, wish to be understood as condemning this line of treatment for the relief of pulmonary tuberculosis, although I am of the opinion that serum therapeutics will find its greatest range of usefulness in the treatment of acute diseases and in the prevention rather than the cure of chronic diseases.

The results which I have obtained, certainly show that serum from the blood of the mule has a limited control over tuberculosis, and even though the results are only temporary, it is highly probable that by increasing the antagonistic properties of the blood by the systematic injection into the animal of toxins designed to increase these natural anti-tubercle powers, the serum might be brought to a state in which its administration would give definite results, as a preventive of tuberculosis and perhaps as a curative agent in the very incipient stages of the disease.

This paper will prove, however, that the eruptions and the pain which have followed the administration of antitoxin in cases of diphtheria are not dependent upon anything peculiar to antitoxin or to its injection into the system of a diphtheritic patient.

The effects of simple primary serum from the blood of the mule, injected hypodermically into the system of persons afflicted with pulmonary or laryngeal tuberculosis may be summarized as follows:

1. A fine rash or eruption producing intense burning and itching, which appears usually from three to ten days following the first administration, and con-

tinues from three to seven days, when it disappears permanently. In some cases it appears only at night, disappearing completely during the day. Exposure to the cold open air makes the eruption more intense. Rubbing or irritation of the rash will produce large eruptions having the appearance of "water blisters" which soon disappear. The intensity of eruption bears no proportion to the amount of serum injected.

2. Severe pains of a neuralgic character which only appear following the administration of a large amount of serum. These pains appear with no regularity whatever, neither are they manifested for any certain length of time. In most cases their severity is governed by the quantity of serum injected. These pains do not yield readily to the influence of opiates or other treatment. They usually appear near the site of the injection, but may appear in a remote region.

3. The typical eruption is accompanied with a pronounced rise of temperature. This temperature is also present some hours before the eruption makes its appearance. Temperature may reach 104 degrees or even higher. It remains at its full height with little or no fluctuation until the eruption becomes less intense.

4. Following the disappearance of the eruption, the temperature drops to normal, or even below normal. If the case is one of acute tuberculosis and has had a high temperature, the diminution of fever will be as pronounced as in the milder form. The temperature will remain nearly normal for two or three days, after which it gradually resumes its former stage. In one or two cases the temperature remained low for nearly one week, but eventually it resumed its former height.

5. Swelling or puffiness of the extremities, lips and eyelids sometimes accompany the eruption, but usually subsides as the eruption disappears. In one case the swelling of the lower limbs persisted in a milder degree for several days after the eruption had disappeared.

6. Subsequent injections of serum do not cause a second eruption, though the pain is liable to return if too much serum is given.

These symptoms or results bear so exact a resemblance to those which many times follow the administration of antitoxin that I venture to assert that one and all of these secondary manifestations, which cause so much annoyance, not to say danger to the convalescent diphtheritic patient, are due to the effects of primary serum. That these manifestations are no more severe following the use of antitoxin than following the use of primary serum.

## CAMPBOR-MENTHOL; A SUPPLEMENTARY REPORT.

BY SETH SCOTT BISHOP, M.D.

SURGEON TO THE ILLINOIS CHARITABLE EYE AND EAR INFIRMARY; PROFESSOR OF DISEASES OF THE NOSE, THROAT AND EAR, CHICAGO SUMMER SCHOOL OF MEDICINE; PROFESSOR IN THE POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, ETC.  
CHICAGO.

Since the introduction of this remedy at the meeting of the Mississippi Valley Medical Association in 1891, and published in the JOURNAL, it has come into quite general use for catarrhal conditions of the upper respiratory tract. But inquiries have not ceased to come from various parts of the country concern-

ing the method of its application, and for the details of my experience with it since. The purpose of these notes is to answer such questions.

Although I did not recommend its use until long after I had discovered that the union of these two camphors resulted in a fluid of the chemic formula  $C_{10}H_{18}O$ , and after I had satisfied myself that we possessed a valuable remedy in this new drug, I am now able to express greater confidence, and to verify my former statements by the experience of others, as well as by my daily use of it up to the present time. The experimental stage has passed, and the efficacy of this medicine is clearly established. Specialists who were at first skeptical as to its virtue, have since adopted it as a standard remedy in both private and dispensary practice. I have taken pains to ascertain the results of their experiences, and add them to my own.

The field of application in which camphor-menthol has proved most efficacious is in the following diseases: coryza, hay fever, intumescent rhinitis (intermittent and alternating nasal stenosis), hypertrophic rhinitis, simple sore throat, acute laryngitis, tracheitis, bronchitis, and cauterizations to prevent hemorrhage and inflammation.

The indications for its use are made clear by a consideration of its physiologic action. It contracts the capillary blood vessels of the mucous membrane, reduces swelling, arrests sneezing and irritation, checks excessive discharges, and corrects perverted secretions.

For home use and ordinary office treatment, I do not employ a stronger solution than the 3 per cent. in lavolin, and for very sensitive cases, like hay fever sufferers, the 1 or 2 per cent. solution at first. The lavolin itself is a bland and soothing protective to the membrane, and in the combinations indicated we have undoubtedly the most effective and harmless remedy known. This means a great deal to both patient and physician, for most of the sprays in use give indifferent results—or worse. Indeed, so great has been the disappointment with the old local medicaments, that a well-known writer on nasal diseases entirely abandoned them several years ago.

Patients should be instructed to treat themselves thoroughly every night at bed time, by throwing a spray of the 3 per cent. solution from a lavolin atomizer into both nostrils while slowly inhaling. The rubber bulb should be forcibly and rapidly compressed at least eight times for each nostril. For the throat, larynx or bronchial tubes, the spray should be thrown through the mouth also during inhalation.

In diphtheria, croup, etc., in infants, when it is very difficult to throw a spray into the throat, the medicine may be made to reach the parts by volatilizing it, by placing a few drops of the pure undiluted camphor-menthol in hot water, and causing the patient to breathe the medicated steam, or a few drops can be heated in a spoon over a lamp, and its fumes will impregnate all the atmosphere of the room. Enough medicine need not be used to cause uncomfortable smarting of the eyes. Inflammation of the throat, larynx, trachea and bronchi can be effectually treated by inhaling the camphor-menthol steam from the benzoinol inhaler.

I have found that we can prevent hemorrhage and inflammation, following galvano-cauterization of the turbinated bodies, by gently packing a pledget of cotton wet with a 20 per cent. solution of the cam-

phor-menthol between the burned tissue and the septum, and leaving it there twenty-four or forty-eight hours. It is then replaced by a fresh dressing and, at the end of four or five days, instead of finding sloughs filling the passages, swelling and stenosis, the tissues appear shrunken and mummified, and the strait is clear. Unless the electrode has been allowed to cool before removing, no hemorrhage or only slight oozing occurs. There is also less discomfort following this method than after others. The cotton should not be saturated to dripping with the solution, so as to allow it to trickle down into the throat, and if too much is used, it occasions a copious serous secretion. Advantage of this power of the strong solution to cause stimulation of the glands, and osmosis, can be taken in treating ozena and dry catarrh of the nose and throat. The weak solutions diminish secretions; the strong ones increase them.

Much suffering can be prevented in people who take cold easily, by using the pocket camphor-menthol inhaler. Any one can easily construct it. I have them made, however, with an excess of camphor, while the pure camphor-menthol contains a larger proportion of menthol. By inhaling this for a moment, the instant the irritation of a cold is felt in the nose or throat, the attack can be stopped. Patients who carry these inhalers in their pockets are able to prevent colds during the seasons when they have heretofore suffered repeatedly.

In my first paper on this subject, I gave the directions for preparing this formula, but I have since come to prefer a preparation that is made more cheaply and elegantly for me by Truax, Greene & Co., of Chicago.

Columbus Memorial Building.

## CLINICAL VALUE OF THE CHEMIC ANALYSIS OF GASTRIC JUICE.

BY B. BECKER, M.D.

TOLEDO, OHIO.

Professor Bourget, at Lausanne, being looked upon as authority on all questions concerning the chemistry of the stomach, was invited by the organizing committee of the French Congress for Medicine at Lyon, to give a full report of the named question. The result of his experience, gathered during a number of years from 354 patients, differs in many respects from the views of many physicians at the present time, and a sketch of his resumé must be of interest to the readers of the JOURNAL.

Bourget examines the contents of the stomachs of his patients before breakfast, and after a test meal of 200 cubic centimeters of beef tea, 80 grams of chopped meat and 40 grams of bread. After two and one-half hours of digestion, the stomach is emptied by the stomach tube, without aspiration, simply by the contraction of the muscles of the stomach, which under certain conditions is promoted by the insufflation of a small quantity of air. Having emptied in this manner the larger amount of the contents of the stomach, he pours 100 cubic centimeters of water into the organ and empties the same immediately after. By the analysis of the diluted, as well as the undiluted fluid, an exact measuring of the quantity of the contents of the stomach at the time of the experiment is possible. Beside this, an analysis of the acidity *in toto*, of the amount of free as well as combined hydrochloric acid, of organic acids, etc., is made. For

the examination of the total acidity with one-tenth strength of the normal caustic soda, Bourget prefers azolithmin to phenolphthalein, which is mostly used as an indicator, because the latter is unreliable in the presence of peptones. The relation of the acidity of the undiluted to the diluted gastric juice allows the correct estimation of the absolute quantity of acids. For the qualitative analysis of free acid, Bourget uses phloroglucin-vanilin or Boas' resorcin test, while for the quantitative HCl test he usually uses the method of Hazen and Winter.

In young individuals with healthy stomachs, free hydrochloric acid is *always* present. Even after a meal of 300 grams of meat, a percentage of 0.03 to 0.05 of free hydrochloric acid is found, while the quantity of combined hydrochloric acid fluctuates between 0.20 to 0.25 per cent. This gives the impression that the healthy mucous membrane of the stomach has the power to secrete such a quantity of this acid which is in proportion to the amount of nourishment, and that after the saturation of the bases and albuminates, a certain excess of free acid remains.

In all diseased conditions, which lower the activity of nutrition, as chlorosis, anemia, chronic nephritis, etc., the quantity of HCl is diminished. In chlorosis and anemia, free hydrochloric acid is often entirely absent. In neurasthenia great fluctuations are observed; the same patient can have hyperchlorhydria on one day and on the next day he may produce a distinctly hypochlorhydric gastric juice, according to his momentary mental disposition. During the periods of depression, the quantity of hydrochloric acid is usually diminished. In cases of gastrectasis and gastroparesis, the secretion of HCl seems to depend on the motility of the stomach. As long as the stomach is emptied in the normal way, the condition of the gastric juice is almost normal, even in well marked dislocations of the organ. If, on the other hand, the motility of the stomach is insufficient, the juice is also altered by-and-by; free hydrochloric acid disappears first, while the percentage of combined acid diminishes later on.

For some time it was thought that in malignant tumors of the stomach, especially in carcinoma, the absence of free hydrochloric acid was almost a pathognomonic symptom of this disease. That this in fact is not the case is proved by the observations of Bourget, who found free hydrochloric acid in nine cases out of twenty-five of carcinoma of the stomach.

Hypochlorhydria is found in a large number of cases of dyspeptic trouble, which are usually described under the general name of gastritis. The quantity of free, as well as combined HCl, is increased; a quantity of 0.18 per cent. of free and of 0.26 per cent. of combined acid is not rarely found. In Reichmann's disease (continued hyper-secretion of gastric juice) the relative quantity of hydrochloric acid can be normal, or hypochlorhydria may exist; while in all such cases the total quantity of the acid is rather large. In one patient of this kind, Bourget found, for instance, after the test meal, 18 grams of concentrated HCl, with a specific gravity of 1.016, diluted in two quarts of gastric juice which had gathered in the stomach after the test meal.

There is always found a sufficient quantity of pepsin in any gastric juice; even in advanced cases of carcinoma the peptic power of the gastric juice is always sufficient. It was only in two cases of atrophy

of the mucous membrane of the stomach that Bourget could observe the absence of pepsin in the juice. The mercantile preparations of pepsin show a very high digestive power in the chemic test tube, but after the addition of pepsin to the physiologic gastric juice the digestive power of the latter is largely diminished, about one-half after the addition of 0.5 per cent. of pepsin.

Lactic acid is found in those cases where the contents of the stomach remain for a long time in this organ, especially when at the same time hypochlorhydria exists. This is often the case in carcinoma. Butyric and acetic acids are formed under similar conditions. The latter is often formed in Reichmann's disease, because different kinds of fungi of fermentation can very well exist in a 2 per cent. solution of hydrochloric acid.

Now then, what is the clinical value of the chemic analysis of gastric juice? Admitted that it gives some valuable information, we can not form a definite conclusion by it as to the activity of the stomach during digestion. It considers only one side of the question and leaves three points entirely untouched, which are of the greatest importance for the act of digestion:

1. The permanent secretion of gastric juice during the whole time of digestion.

2. The absorption by the mucous membrane of the stomach.

3. The emptying of the stomach into the intestine.

Furthermore, we are not allowed to judge as to digestion in general from the energy of the digestion of the stomach. The digestion of the stomach does not represent more, in a certain sense, than a preparation for intestinal digestion. The latter can be entirely sufficient to support life, while the digestive power of the stomach is impaired. The peptones which are formed in the stomach are not ready yet for assimilation according to the views of Bourget. After the subcutaneous or intravenous injection of peptones formed by the stomach, it was observed that they were eliminated by the urine, and plain symptoms of intoxication were found during this process. If, however, these gastric peptones had been brought in contact with intestinal juice for some length of time, no symptoms of intoxication were observed after their injection, and no peptones were found in the urine.

We also should be careful in our diagnostic conclusions from the chemic analysis of gastric juice. A positive diagnosis of Reichmann's disease only can be made by this analysis. In all other affections, especially in the different forms of gastritis, the chemistry of the stomach is so changeable that upon this alone no positive opinion should be based. In one and the same disease, at certain times, hyperacidity is found; at other times hypoacidity, and again at other times, normal conditions are observed. Sometimes, during the course of the same disease, the result of the chemic tests changes entirely—a primary hyperchlorhydria turning into hypochlorhydria. This goes to show that chemic analysis alone does not justify a positive diagnosis of disorders of the stomach. An examination of the motory action of the organ should never be omitted, because we can draw better conclusions by it as to the general disorders of digestion than by chemic examination only. In consequence of this, a classification of the diseases of the stomach based on the chemic test alone, should not be made. The most important

value of the chemic analysis of gastric juice is that it serves as a guide in therapeutic procedures. We will base on it our dietary and medicinal treatment, knowing if hydrochloric acid or alkalins are indicated in a given case.

Beside the observation of the chemic and motor activity of the stomach, the estimation of the position and size of the organ should never be forgotten. To this end, Bourget recommends insufflation of the stomach. Air is blown into the stomach until the patient perceives a certain sensation of pain, which will set in as soon as the stomach has reached the limit of its normal expansibility. A flabby belly exposes the border of the stomach to the eyesight directly, and it can be marked with a blue pencil, while in a tense and fatty abdominal wall the demarkation has to be made out by percussion. The quantity of the insufflated air indicates the size of the organ. A healthy stomach usually reacts after the insufflation of fifteen to eighteen hundred cubic centimeters of air, while in certain diseases it may receive as much as five quarts before the limit of the expansibility is reached. In this way we can easily differentiate between an ordinary dilatation of the stomach and gastropstosis, vertical dislocation, etc.

### ERRORS OF REFRACTION.

A SYLLABUS OF THE LECTURE DELIVERED IN THE JANUARY EVENING COURSE TO THE PHYSICIANS OF THE SPECIAL OPHTHALMOLOGIC CLASS AT THE POST-GRADUATE MEDICAL SCHOOL.

BY FRANCES DICKINSON, M.D.

CHICAGO.

These eighteen propositions will assist the beginner to more readily understand the many pages treating of the same subjects in all our text-books.

With a second lecture on the lenses which correct the errors of refraction, and a third lecture on the frames which hold the lenses which correct the errors of refraction, we will have completed the "House that Jack Built."

1. Three essentials to sight—Light; eye; brain.
2. Three characteristics of light; it proceeds—From every point; in every direction; along straight lines called *Rays*.
3. Three directions to rays of light—Parallel; divergent; convergent.
4. Three destinies for light—Absorbed; reflected; refracted.
5. Three varieties of forms of glass reflect light—Plane; prism; curved surfaces.
6. Three combinations of curved surfaces converge rays of light—Convex spherical; convex cylindrical; convex spherocylindrical.
7. Three combinations of curved surfaces diverge rays of light—Concave spherical; concave cylindrical; concave spherocylindrical.
8. Three refracting surfaces in the eye—Anterior surface of cornea; anterior surface of lens; anterior surface of vitreous.
9. The combined effect of the three refractive surfaces of the eye on the rays of light, be they parallel, divergent or convergent rays is to—Converge the rays; converge the rays alike in every meridian; converge the rays to a point focus; as would a convex spherical lens.
10. Three positions for the foci of all rays of light entering a convex spherical lens, *i. e.*, at, before, and behind the principal focus, or—Entering parallel rays are focused at the principal focus; entering

converging rays are focused before the principal focus; entering diverging rays are focused behind the principal focus.

11. Three directions given to rays of light emerging from a convex spherical lens, *i. e.*, parallel, diverging and converging, or—Parallel emerging rays when proceeding from the principal focus; diverging emerging rays when proceeding from a point before the principal focus; converging emerging rays when proceeding from a point behind the principal focus.

12. Three positions for the foci of all rays of light entering the normal refractive media of the eye, making three possible positions for the retina—Entering parallel rays are focused at the principal focus of the refractive media of the eye or on an emmetropic retina; entering converging rays are focused before the principal focus of the refractive media of the eye, or on a hyperopic retina; entering diverging rays are focused behind the principal focus of the refractive media of the eye, or on a myopic retina.

13. Three directions given to light emerging from the normal refractive media of the eye—Parallel emerging rays when proceeding from the emmetropic retina; diverging emerging rays when proceeding from the hyperopic retina; converging emerging rays when proceeding from the myopic retina.

14. Three varieties of meridional or curvature refraction of the refractive media of the eye—Every meridian or curvature may refract alike; the two principal meridians (any two meridians at right angles to each other) may refract unequally, regular astigmatism; different parts of the same meridian may refract unequally, irregular astigmatism.

15. Three conditions of the eye refract alike in every meridian or curvature—Emmetropia; hypermetropia; myopia.

16. Three varieties of regular astigmatism—One meridian may be emmetropic, the other hyperopic or myopic, simple astigmatism; both meridians may be hyperopic, one more so than the other, or both myopic, one more so than the other, compound astigmatism; one meridian may be hyperopic and the other myopic, mixed astigmatism.

17. Three varieties of irregular astigmatism—When the meridians of greatest and least curvature or refraction are not at right angles to each other; when the cornea is conical; when different parts of the same meridian refract unequally.

18. Three refractive abnormalities—Axial myopia or hyperopia—antero-posterior diameter too long or too short; curvature myopia or hyperopia—curvature too great or too little; index myopia or hyperopia—refracting power of media too great or too feeble.

### ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.  
NEW ORLEANS, LA.

(Continued from page 633.)

#### CHAPTER X.

#### BLACK VOMIT OF YELLOW FEVER.

The following observations on the black vomit of yellow fever, are the results of labors begun in 1856,

and pursued, in various portions of the Southern States, up to the present time.

I have shown, by numerous careful post-mortem examinations, and by analysis of the blood, black vomit, and urine during life, in various stages of the disease, that:

During the active stages of yellow fever, profound changes take place in the organs and tissues, and especially in the kidneys, heart and liver; and oil and granular fibrinous or fibroid matters (altered albumin and fibrin), transude through the capillaries and fill up the cells and excretory ducts, and arrest or impair the functions of these organs.

The liver of yellow fever does not present the soft friable condition characteristic of true fatty degeneration. The jaundice resulting from the suppression of the excretory function of the liver, would appear to be due to the same causes which induced the suppression of urine, namely, to the deposit of oil and fibrinous matters in the excretory structures of the kidney and liver.

The heart, in yellow fever, appears to be as fully permeated with oil as the liver; in the latter organ, however, a large amount of the oil is inclosed within the liver cells.

Yellow fever is not only attended with what might be called "acute fatty degeneration," but also with such profound alterations of the fibroid elements of the blood as to permit the transudation of the altered fibrin and albumin, through the walls of the capillaries, into the excretory tubes.

*Black Vomit.*—This ejection of altered blood from the mucous membrane of the stomach, during the period of calm or depression, although not absolutely characteristic of yellow fever, as it may occur in other diseases, is still of so frequent occurrence in yellow fever as to demand the most careful consideration, both as to its nature and origin.

The character of the matters vomited during the progress of yellow fever varies in different stages of the disease, and with the character, relative mildness and severity, and the progress of the changes in the blood and organs.

While yellow fever is characterized, in common with several other diseased states, by an irritation of the gastric mucous membrane, the peculiar nature of the vomited matters does not rest entirely upon the congestion and irritation of the mucous membrane of the stomach, but is influenced to a greater or less extent by the changes of the blood, liver, kidneys and nervous system.

The vomiting in yellow fever may also be regarded, to a certain extent, as salutary, and as an effort for the elimination of certain excrementitious materials from the blood. In some cases, the first effects of the black vomit may seem to be salutary; the tongue improves in appearance, the febrile heat abates, and if it were not for other profound changes in the blood, liver and kidneys, lying back, as it were, of this almost universally fatal symptom, beneficial results of the most important character might flow from the relief afforded by the removal of a certain amount of excrementitious matter, as urea and ammonia from the blood.

The first ejections of the stomach of a yellow fever patient consist most generally of the ordinary secretions and contents of the stomach, then follow vomiting of a mucoid fluid, frequently at first tinged with bile, the reaction of which varies in different cases, being alkaline in some and acid in others.

After the first vomiting the stomach may remain tolerably quiet until the subsidence of the fever on the third or fourth day, when, without any premonitory symptom of nausea, the stomach, on any trifling provocation, may eject a quantity of clear, pale, almost limpid and slightly acid, opalescent fluid. At this period the disease may terminate, or make no farther progress, as if this elimination was similar to the perspiration of intermittent fever, the whole ailment vanishing at this stage. If the vomiting continues and passes on to black vomit, it becomes first streaked with dark flocculi of altered blood; the reaction, in many cases, changes from the acid to the alkaline, and careful chemic examinations have convinced me that this change in the reaction of the black vomit was due to the elimination by the gastric mucous membrane of urea, and its conversion into ammonia.

The acid reaction of the yellow fever vomit is due not to the presence of any peculiar acid, but to several, as the phosphoric acid, existing in the form of acid phosphates, acetic and hydrochloric acids. The degree of the acidity will also vary with the character of the fluids and solids taken into the stomach; thus, if much sugar be taken, the vomited matters will be much more strongly acid, and the presence of this substance will also determine, to a great extent, the presence and development of certain fungi, as the yeast plant.

The rapid generation of *torulæ*, as well as the effervescence of the black vomit, in certain cases, is referable chiefly to the presence of sugar in the aliment, and in the tea and coffee drunk.

I have observed various forms of coniomycetous fungi in the black vomit of yellow fever, but I have by parallel experiments, and microscopic examinations of urine and various other organic liquids, failed to find any distinct species characteristic of yellow fever. If the black vomit be allowed to stand for days and weeks, and be carefully examined at intervals with the microscope, we see various forms of the coniomycetous fungi, as *torula*, *sacchari* or *cerevisiæ*, *cryptococcus*, and *penicillium glaucum*; and of the hyphomycetous fungi, as *oidium lactis*, and *oidium albicans*; and of the physomycetous fungi (*mucor*); and of the *torulaci*. Upon one occasion, during these investigations, I submitted one of these fungi from the black vomit of yellow fever to the observation of an excellent microscopist of this city, Mr. Kinttschmitt, and the following is his reply:

NEW ORLEANS, NOV. 10, 1873.

*My Dear Sir:*—I have subjected the filtrate from black vomit, which you recently placed at my disposal, to a very careful microscopic examination and comparison with other fungoid growths, of which I have several prepared slides in my possession.

The fungoid growth developing in the filtrate of black vomit has certain points in common with *torula*, *oidium* and *mucor*, and if *torula* be a submerged form of *penicillium*, also to the latter fungus; it also resembles the filamentous development of bacteria, the same as the fungoid growths developing in a solution of gamboge. The diagram which Virchow furnishes of the *aspergillus* fungus discovered by him in the human lung, has a strong likeness to the black vomit fungus.

There is a doubt, however, in my mind, that yellow fever is not produced by a specific fungus; but the fungus, if produced in the human body at all, is produced by the sickness itself; but it is most likely that the fungoid growth only makes its appearance after the vomit has been ejected from the stomach.

The slides on which the foregoing remarks are based, had been prepared on 2d inst. On examining them again yester-

day, the fungus has in a measure disappeared, and granular masses seem to have taken its place. I remain, my dear sir, very respectfully,  
P. KINTSCHMITT.

The specific gravity of black vomit, as determined by weighing, with the specific gravity bottled, varies from near the standard of distilled water to near that of blood.

It is now fully admitted that black vomit is not entirely confined to yellow fever, and that it is chiefly the secretion of the mucous membrane of the stomach, and the matters introduced from without as food, mingled with the blood which oozes slowly into this viscus, from the mucous surfaces denuded of mucous epithelium.

But in most cases, black vomit is something more; it is to a certain extent an excrementitious product, containing urea and carbonate of ammonia.

The kidneys are more or less affected in every case of yellow fever; when they act continuously and freely, the blood is freed of bile and urea, and black vomit more rarely occurs than in those cases in which their functions are arrested, and the mucous membrane of the stomach assumes the excretory function.

Black vomit is due to several causes:

1. To the direct irritation and structural alteration of the gastric mucous membrane, by the poison of yellow fever. This poison is most probably received into the blood and acts in this manner, or through this medium upon the gastric mucous membrane, for we find cotemporaneous changes taking place in the heart, liver and kidneys; and these changes would most probably succeed the gastric irritation, if the poison was received in food or drink, primarily by the stomach.

2. To the structural alterations of the blood, and especially to the marked diminution of the fibrinous element, which appears to sink to a lower figure than in any other known diseased state. It is well known that the diminution of the fibrinous element, below a certain standard of health, so deranges the capillary circulation as to lead to congestion, alteration of nutrition and secretion, and passive hemorrhages. The hemorrhages and effusions of scurvy can only be referred, with reason, to the changes of the blood, and especially of the fibrin.

3. To suppression of the action of the kidneys, and retention in the blood of urea and other excrementitious products, and the elimination of urea, and carbonate of ammonia and ammonia, by the gastro-intestinal mucous membrane.

4. To the direct irritant action of the ammonia, and excrementitious materials eliminated vicariously, upon the mucous membrane of the stomach and intestines.

Bernard and Frerichs long since explained, by experiments, what we observe in those cases of yellow fever attended with urinary suppression. Thus the former experimenter found that a dog, which had a fistulous opening in the stomach, passed daily with his urine about 93 grains of urea and uric acid, and yet during the succeeding twenty-four hours after the removal of the kidneys, the blood drawn from this animal exhibited only a mere trace of these constituents, but urea in abundance was detected in the gastric juice withdrawn through the fistula; and after remaining for some time in the stomach and intestine, the urea changed into ammoniacal salts, and the gastric juice was secreted continuously and not, as in the normal condition, only after a meal.

Not only were the manner of formation and chemico-constitution of the secretion of gastric juice altered by this vicarious excretion of the main constituent of the urine, but the mucous membrane was structurally altered, and became disqualified not only for the performance of this eliminative action, but also for the elaboration of its normal secretion.

In yellow fever, the suppression of the action of the kidneys follows immediately after, or may even begin in the midst of a devastating fever, attended with repeated alteration and chemico-change of the elements of the blood, and the formation of large amounts of urea and other excrementitious matters, and the work suddenly thrown upon the already weakened and altered stomach is far greater than when the kidneys are amputated in a healthy dog, or when their sudden suppression is from the action of cold. Bidder and Schmidt have shown that the digestive powers of the gastric juice are weakened, if it be mixed with any considerable quantity of saliva, in consequence, as they suppose, of the neutralization of the free acid by the alkali of the saliva; and they also found that the addition of bile to the normal gastric juice entirely suspended its digestive property, although the mixture still exhibited an acid reaction. Bernard, Bidder and Schmidt found that gastric juice, secreted with urea, sooner or later not only became alkaline, but also lost its power of converting albuminous matters into assimilable forms; and Lehman also found that the digestive power of the gastric juice was much impaired by the addition of alkaline salts, or by saturating the fluid with peptones or other organic substances, either nitrogenous or non-nitrogenous.

In yellow fever, when there is an impairment or suppression of the function of the kidneys, we not only have a combination of these various causes, producing derangement of the gastric juice, but we also have the destruction of the fibrin of the blood, inducing passive hemorrhages from the congested and altered gastric mucous membrane, and at the same time such an elevation of temperature as is most favorable to the rapid decomposition of the contents of the enfeebled stomach and intestines.

5. To the irritant and nauseating effects of the bile retained in the blood. The bile retained in the blood, without doubt produces its characteristic effects upon the nerves supplying the stomach, producing nausea and vomiting.

6. To the degeneration of the excretory and secretory cells of the gastro-intestinal mucous membrane, attended with or characterized by the deposit of granular fibroid or albuminous matters and oil globules in the secreting cells, and in the walls of the smaller blood vessels or capillaries.

7. To the capillary congestion of the gastro-intestinal mucous membrane, similar in all respects to the intense capillary congestion which characterizes all the organs and tissues in this fever.

The chief causes of black vomit therefore are: the direct irritation of the gastric mucous membrane; intense capillary congestion, in consequence of the morbid action of the poison of yellow fever, and its products, upon the vasomotor system of nerves; suppression of the functions of the liver and kidneys, and the retention in the blood of bile and urea, and the elimination of urea from the gastro-mucous membrane, as such, and in the state of ammonia and carbonate of ammonia; and the direct irritant and sol-

vent effects of ammonia and carbonate of ammonia, upon the gastro-intestinal mucous membrane and the effects of the urea, ammonia, and other constituents of the metamorphosis of the tissues upon the blood; the alterations of this fluid by the changes excited by the yellow fever poison, and the destruction and alteration of the fibrinous element.

When careful sections of the kidneys were made with Valentin's knife and examined under the microscope, the Malpighian corpuscles and tubuli uriniferi were filled with oil globules and granular fibroid matters, which appeared to be modifications of fibrin and albumin. The excretory cells of the kidneys also contained oil globules and granular matter.

The poison of yellow fever appears to act in an analogous manner to the agent producing smallpox, or the poison of certain reptiles, which alter the constitution of the blood, and lead to the formation of altered albuminous and fibrinous products from the blood; and which in the case of yellow fever transude into the hepatic ducts and urinary tubes, and thus cause suppression of the urinary and biliary secretions.

When in any case of yellow fever the function of the kidneys is arrested, a fatal result necessarily ensues, not only from the retention of the urinary constituents, but also from the retention of the bile.

As long as the kidneys perform their normal function, the retained bile will be continuously eliminated; but as soon as these organs cease to act, the bile, as well as the urinary excretion, is retained in the blood, and certain nervous disturbances are induced, as dullness of the intellect, uremic convulsions, and in some cases violent agitation of the muscles resembling tetanic spasms.

Black vomit, therefore, is an *effect* or *result* of preceding actions or changes, and is not a cause; it is an error therefore to search, either by chemic means or by the microscope for the *cause* of the disease in one of its *products*.

Black vomit, from its great amount, may be one of the causes of death; but as it is, in many cases at least, the result of an effort on the part of the living organism to eliminate certain materials from the blood, it may be to a certain extent salutary; but it is in all cases, only secondary to the preceding changes in the blood, heart, liver and kidneys.

In the preceding chapters we have given the practical results of the microscopic and chemic examinations of the black vomit in various stages of yellow fever; similar facts will also be presented in the succeeding chapter on the changes of the urine; the following cases are presented in this connection as direct demonstrations of the generalizations just recorded:

*Case 1.*—Yellow fever, jaundice, suppression of urine, black vomit, death. G. G., age 22, laborer; native of Canada. Entered Charity Hospital Oct. 18, 1873. Attacked with yellow fever October 14. Has been driving a street car, and has resided on Napoleon Avenue near the Mississippi River, in one of the so-called infected districts. Has resided in New Orleans four years; states that his attack began with "universal pain all over the body," which was greatest in the forehead and lumbar region. Fever began with chilly sensations. October 18, evening; has just entered the hospital. This is the fourth day of the disease. Pulse 100; respiration 30; temperature of axilla 105.5 F. Tongue very red at tip and edges, and coated with yellow fur in the center. Conjunctiva yellow and congested. Surface of the entire body yellow, with marked capillary congestion. Gums red. No appetite. Body emits a disagreeable odor. Patient restless and nervous, and although answering questions slowly

appears to be in an unnatural state. Complains of pains in all parts of his body.

October 19, 8 A.M., tongue very red at tip and edges and furred in center. Gums very red. Conjunctiva of eyes congested and yellow; body deeply jaundiced, with great peripheral capillary congestion. Eyes have a wild restless expression. Stools light colored. Patient has passed no urine and his bladder is not distended. Restless, uneasy, sleepless, with great mental hebetude and confusion. Pulse 90; respiration 26; temperature of axilla 103.10. 8 P.M., intellect confused and stupid; tongue red at tip and edges. Patient very restless, tries to get out of bed incessantly and says that he wishes to go home. Face expressive of sorrow and grief. No urine has been obtained during the night or day; complete suppression. Pulse 90; respiration 26; temperature of axilla 102. Black vomit runs from corners of the mouth and appears to regurgitate from the stomach without any effort on the part of the patient, who continued very restless during the night and died at 6:30 A.M., October 20. Black vomit continued to run out of his mouth up to the time of death.

Autopsy, at 9 A.M., October 20, three hours after death. Exterior of body still warm. The warmth was diffused over the entire body. Face and limbs full and round. Surface of skin greenish-yellow; dependent portions of neck, face, trunk and extremities mottled. Black vomit running in streams from both corners of the mouth. When the body was turned on its side in placing it on the table, a considerable amount of dark blood or black vomit poured out of the mouth. The ease with which the black vomit poured out of the mouth indicated great relaxation of the muscular coats of the esophagus and stomach. Immediately after opening the thorax, I introduced the bulb of a delicate thermometer into the right ventricle of the heart, and found the temperature to be 100.5 F. It is not probable that any great degree of heat had been lost during the short period of time which had elapsed after death. Dependent portions of lungs congested, otherwise normal. Muscular structures of heart apparently greatly congested, giving the surface of the organ a deep color, as in malarial fever; but when the walls of the heart were cut through and the organ carefully washed under a stream of water the muscular structures presented the characteristic yellow color of yellow fever. Muscles of heart softened and readily crushed under the fingers. Under the microscope the muscular fibrillæ of the heart were found to contain numerous oil globules and much yellow granular matter; the oil and granular matter were, however, not so abundant as in cases in which death took place at a later stage. Cavities of heart distended with dark liquid blood; also a small golden-colored fibrous clot. Stomach distended with about one quart of dark, grumous, fluid black blood, or black vomit. Mucous membrane of stomach greatly congested and mottled, presenting deep purplish spots or ecchymoses, and from these portions the black vomit appears to have flowed from the congested and ruptured blood vessels. Small intestines contained blood.

The liver was congested, presenting a dark mottled appearance on the surface; many yellow lobuli, however, were readily discerned upon the surface, resembling in all respects the yellow color of the liver in yellow fever. The congestion of the capillaries of the liver was so great, however, that the organ presented more nearly the hue of some recent fatal cases of malarial fever. When thin sections of the liver were made, and the excess of blood gently pressed out and the slices washed under a stream of water, the color resembled in all respects that of yellow fever. Liver loaded with oil globules and yellow granular

matter. Liver cells contained oil globules and were of a distinct yellow color.

When the great excess of blood with which the kidneys were congested was washed away, these organs presented the usual color of yellow fever. Sections with Valentin's knife, viewed under the microscope revealed the Malpighian corpuscles and tubuli uriniferi, filled with detached cells, oil globules and yellow granular matter. The urinary bladder contained about two fluid ounces of urine, which represented the amount excreted during the last thirty-six hours of life. Detected no coloring matter of bile in urine. Acid reaction. Slightly turbid. Light yellow color. Urine contained albumin, urinary cells from excretory tubes and from pelvis of kidney, and casts of tubuli uriniferi. Examination of black vomit from the stomach. Reaction acid; contained numerous colored blood corpuscles, masses of hematin, oil globules, granular matter, cells from mucous membrane, casts of gastric glands, and broken capillaries. Sp. gr. 1016.7. Upon careful analysis, the black vomit contained urea and ammonia, acetic and hydrochloric acid. No hydrocyanic acid was present. The hydrochloric acid loses to a certain extent, for it could be driven off by heating the black vomit gently in a beaker on the sand bath, and its fumes reddened litmus blue, and decomposed nitrate of silver. When thrown upon a filter, the filtrate presented a brownish-red yellow color. Sp. gr. of filtrate of black vomit 1013.2. When the filtrate of the black vomit was treated with nitric acid the albumin coagulated, but the coagulum re-dissolved in boiling. I was unable to detect the biliary coloring matter in the filtrate of the black vomit. Alcohol added to the filtrate coagulated the albumin. Sp. gr. of black vomit 1016.7. Sp. gr. of filtrate from black vomit after removal of blood corpuscles and organized bodies 1013.2.

Solid residue in 1000 parts of black vomit . . . . .	56.15.
" " " " " filtrate from black vomit. 46.60.	
Hematin, blood corpuscles and organized elements in 1000 parts of black vomit . . . . .	9.55.

When the filtered liquid from the black vomit was set aside, a delicate fungoid plant resembling the torula was developed. This delicate fungus had certain points in common with torula, oidium or mucor; and if torula be a form of penesidium, also to the latter fungus. It also resembles the filamentous development of bacteria. A similar fungus has been observed developing in gamboge.

(To be continued.)

## PRE-COLUMBIAN LEPROSY.

BY ALBERT S. ASHMEAD, M.D.

LATE FOREIGN MEDICAL DIRECTOR, TOKIO HOSPITAL, JAPAN.  
NEW YORK.

(Continued from page 626.)

Dr. Manuel A. Muniz, of Lima, Peru, in the *Cronica Medica* of 1886, contributes an article entitled, "La Lepra en el Peru." His notes were taken from the Historical Discourse on the Foundation and Rights of the Hospital San Lazaro, Lima, by Bravo de Lagunas, published in Lima, 1761. This work is in the library of Santiago de Chile. Dr. Lagunas shows the first royal ordinance for the care of lepers and for the foundation of a hospital was made in the time of Charles III. In 1693, the alms were ordered to be used for the support of a hospital for Indians. Finally, Philip II. prescribes that such sick persons

as are afflicted with contagious diseases be carried to elevated localities, from which no defiled wind having passed the hospitals, can flow down and reach the healthy population of the lowlands.

Dr. Muniz mentions the first leper hospital at Lima, built by Anton Sanchez, a citizen of that place in 1563. In 1606, according to the same authority, Lima was full of lepers, and those unfortunate persons were too much for San Lazaro; they were admitted elsewhere, and many of them died unknown and without assistance, even without the sacrament. Fear was expressed lest the infection should spread over the whole country, and the successors of Sanchez took care that all lepers should be received in their enlarged hospitals, which consisted of three houses; one for men, one for women, one for negroes. All lepers to be received, unless they were slaves. As to the latter, their master was bound to take care of them during the first year. It is said that these masters used to evade this obligation, by antedating the outbreak of the disease. These buildings are to-day tenement houses, having outlived the terrible scourge against which they had been built. In 1639, the chronicler Cobo mentions the hospital San Lazaro, slightly, saying that it was very poor, and little resorted to, which proves that the disease had already broken its wings. Bravo de Lagunas corrects the error of Echave, who states that San Lazaro was founded for negroes: "All free persons, suffering from San Lazaro's evil, whatever their social position, condition, sex or age, are received in it;" which shows, according to Dr. Muniz, how ill informed was the author of the book, entitled the "Star of Lima," (or Description Sacro-political of the Beauties of the City of Lima, published at Ambers in 1688), when he said that the hospital of San Lazaro was built for negroes, and also Melandez, who says that, failing patients of that color, the hospital would have been empty, if it had not been made into a common sick-house for the falling evil, because the south wind with the cold dryness of the Andes, loses its poisonous qualities, and rather subdues than corrupts the humors. Bravo de Lagunas gives a number of reasons, and quotes authorities to invalidate this testimony. From 1700 till October 1746, this leper hospital was financially successful. Then came the earthquake which destroyed Callao, and partly Lima, and not one stone of the leper hospital was left standing upon another. For over six years the lepers had to live in ill-made cabins or miserable huts. In 1758 the new leper hospital was inaugurated; the money for this purpose had been obtained by lottery. In 1822 the hospital of incurables and that of lepers, were made one. The old leper asylum was converted into a school, and afterward into barracks.

Lagunas tells us that physicians generally assume as a cause of leprosy in those countries, contrary humors which destroy the skin, and are much fostered by bad food, depraved constitution, hot air, uncleanness, slovenliness in places of habitation. "Others who believe in the vermicular system, see the cause of cutaneous diseases and pestilences in small insects, imperceptible gnats which penetrate into the body through the skin, assign this same cause to leprosy. These animalcules stick to the garments, walls and even stones. In this manner, they account for its contagious nature, the insects or seeds pass into other bodies from the air, or by contact with those

parts to which they are attached." Here we have then, the embryo of bacteriology in 1761!

I quote further from Lagunas: "A doctrine in which all eminent physicians agree, and which is also favored by the priests, is that scabies, psora and leprosy only differ in degree. Scabies consists in small pustules which disfigure the skin. In psora, a pernicious itch is added, and if these symptoms are aggravated or extend to the internal parts we have leprosy." Muniz says, however, that they carefully differentiated leprosy and the gallico.

An early law in Lima prescribed that parties of recently introduced negroes should be stopped at a distance of at least one league, before entering the city, and should remain in quarantine until the chapter had satisfied themselves that they were free from contagious diseases; and the city went to the trouble of building houses in the suburbs, on the banks of the river, where the quarantined people could temporarily stay, till they were sold and spread over the country. "It was the same theory of contagion," says Muniz, "which obliged all lepers to use no speech in asking alms, but to make use of bells and wooden timbrels." Evidently the negroes were suspected as a leper importing element.

In the middle of the last century, the leprosy of an illustrious prebendary of the Cathedral of Lima caused a famous litigation.

In 1761, Lagunas says, that "it has been observed in the hospital of San Lazaro, in Lima, that as far back as memory reaches, four persons have been in immediate attendance upon the patients, and never did any of them catch the disease. In this hospital there is now a young woman with furfuraceous leprosy, two patients covered with purulent tumors and who scarcely present human shape, and several others just as wretched, though with smaller deformity. There are others with feet and legs full of scabs, and almost as thick as the body, who in every other respect seem to be well, and have done for many years such services as they were able to perform. There are some whose articulations have given way, or whose fingers have fallen off, and there is another whose foot detached itself altogether, and who walks and stumps along like a trunk. There is a leper whose voice is so raucous, that it reminds you of the snarling of a dog, or of some other moaning animal."

Muniz quotes from Parra, "a Colombian physician, as unfortunate as he was intelligent," who suffered from the terrible effect of the disease, and described in eloquent and graphical pages its pains, its tortments—(Ricardo Parra, of Bogota, Colombia; his work was entitled "La Lepra," and was published in 1850-1860): "The first notable Spaniard who caught leprosy, was one of the conquerors, Gonzalo Jimenes de Quesada; he died of it. There is no doubt that he contracted the disease through contagion, and that therefore leprosy must have been here before the Conquest. In America its resort of predilection was ancient Colombia; it never gained much of a foothold in Peru."

I shall quote Parra at some length to give a clear idea of his etiologic theory: "Elephantiasis is a radical and constitutional asthenia, which tends toward partial gangrene. It is not only a nervous asthenia; it is asthenia of all the elements, organs and functions." Parra nearly forty years ago had an intuition of the microbe. "I shall show," says he, "how an impression, whatever its origin, whether from cosmos

or microcosmos, from the external world or from the organism itself; how such an impression working on a sensitive nerve interferes fatally with a nervous center; how this nervous center by means of an exodid fiber and of a special nerve apparatus, the vasomotors, acts upon the vascular system, contractible in all its extent; how this reflex action hurts and disturbs that system, causing a beginning of paralysis of atonia and weakness in the play of its power of contraction; how these vessels ceasing to act normally, interfere with the blood circulation, and every kind of circulation; how the impediment in the way of the general circulation, checking the free exchange between blood and tissues, and the free contact between the tissues, and all the fluids and humors of the economy, produces principally three things: anemia and asthenia of the nervous centers, anemia and mortification of the tissues, alteration of the composition and even constitution of the blood, and perversion and depravation of all the humors, liquid products, and all the secretions of the organs; how these causes interfere with all the functions of nutrition; how this disease of nutrition in all its functions aggravates and increases the central enervation; how this enervation, already deep-seated, and the perturbations of nutrition, produce general dyscrasia of the humors; and how all these causes together, working and acting, one upon the other, being at the same time causes and effects, engender and produce thousands of abnormal phenomena, which, united with them, in masses, every day increasing with growing and irresistible action, produce successively progressive mortification, slow disorganization, increasing paralysis, and lead finally to extensive phagedena and general gangrene."

Here is another quotation from Parra: "The wrinkles, fissures and scabrosities, the fall of the hair, the desquamation, the general debility, the consumption of the muscle between the index and the thumb, the cold, the atrophy of various parts, but especially that of the vertebral column, must be the immediate effects of the disturbance of nutrition in all its functions, interfered with by the constriction of the terminal extremity of the arteries and capillaries. The turgid countenance, the livid, bluish, ashy or purple color of the face in one form of the disease, and the discoloration of the scalp, the formication and numbness, which are symptoms of myelitis, in the other form; the feeble pulse, slow and heavy, which seems to beat through mud; the inflated, very voluminous veins—all these symptoms of either form must be the natural result of the disturbance of circulation, combined with the disturbance of hematosis and nutrition, cyanosis, black blood, fluid and fibrinless, bluish veins under the tongue, a thick and infiltrated skin, infiltrations of the cellular tissue, edema in various parts, infiltration of the corion, glandular inflammation, diseased condition of all the glandular, disorders of menstruation, epistaxis, at times frequent, affection of all the mucous membranes, are in tuberculous lepra the result of the combinations of the lesions of blood circulation; and all kinds of circulation, of respiration, hematosis and nutrition. And the nutrition perverted and working with a damaged and atonic circulation and corrupt sanguinification, added to cyanosis and swelling of the face and other parts, and to the capricious changes of color, will give us the swelling of the lingual veins, the miliary granulations, the spots, the warts, the tubercles and a

thousand other morbid products; and finally the simultaneous affection of these three functions, added to the lesions of sensibility and motility . . . will give us in combination, the curvature of the fingers, the disarticulations, the muscular debility, the numbness, the lancinating pains, the vague pains, arthritic, vertebral, and finally, the osteocopic pains, and all the pains in their terrible reality; they will give us the vacillating gait, the contracted hand, the crook-legged walking, the spinal curvature; and in another combination they will give us the jumentous urine, the cottonous skin, the forehead bacon-rubbed, exaggerated or malodorous sweat, and the absolute cessation of transpiration, the abscesses and furuncles, the spots of all size by vascular relaxation, the knots and horny spots, the tubercles and ulcers; and in another combination of the same form, all these functions (*danadas*), will give us dyspnea and suffocation, palpitations of the heart, the constriction as with a girdle, the precordial oppression, terrible nightmares, satyriasis, and violent hunger, the thirst and the hydrophobia, the blindness and the photophobia, the libido-inexplebilis, and the motiveless rage, the general despondency and unspeakable torment. And all this in consequence of primitive lesions of the circulation and innervation. All this in consequence of the loss of vital energy effected (*herida*) in the nerves, and effected in the blood, effected through the want of oxygen and effected through the want of nervous influx."

I shall give also Parra's description of a leper hospital; it will show the character of leprosy in ancient Peru and Colombia, and the mutilations which Muniz seems to find represented in the *huacos* pottery:

"in some, the muscles have become pale, weak and are slowly destroyed; in those who follow, the articulations are scooped and excavated, in another the articulation of a foot is detaching itself, in the next the hand is already detached . . . one entirely shorn of muscles and arms, has nothing left but a putrid trunk; but death disdains the mutilated trunk, and these wretches just as they are, feed with voracity, digest well, rave and blaspheme, and burning with lascivious fury, get libidinally drunk, and revel in shameful dreams and filthy faucies. . . . Look, finally, at that hundred of monstrous beings, mixed up together, piled up one on top of the other, and wallowing in the dust. Many have no noses, nor lips, nor ears, nor hair; where the face used to be you see now three or four holes.

. . . The amygdals have fallen, and they can no longer croak; their noses are stopped and they can no longer breathe through them; larynx, pharynx, esophagus have been devoured, and they can not swallow; some are mad with hunger, others devoured by unquenchable thirst. Here are some in whom the raucous roar of the lion has turned to Catilinarian voice and perfect aphonia. In another subject the lungs charged with purulent foci can hardly expand, and here is another whose heart has almost stopped beating. Some weep, others curse, others blaspheme. Others, pusillanimous and craven, tremble and cry for mercy at the least provocation; others laugh danger to scorn, and careless whatever may happen to them, die with stoical indifference. Unceasingly flowing tears and a viscous glutinous humor keeps their red and inflamed eyelids apart, so that many lie blind or grope blindly in the darkness. Many of them have frightful dreams and awake roaring like lions or howl-

ing like wolves. The urine of all these men is thick (jumentous) like that of the horse, or clear and raw, as if passed through a filthy filter; there are no sewers more mephitic than their defecations. Some of them lie motionless and entirely paralyzed, and as, at the same time they can neither articulate nor swallow, they are dying of hunger and parched with thirst, not being able to ask for help. All secrete a fetid sanies over the whole body, and breathe an air which they themselves have poisoned. . . . A horrible caries consumes all the articulations and causes the severance of the limbs, which fall off by pieces, the phalanges of the fingers are shaken off and the teeth break forth from their sockets. . . . Some of these trunks talk; demented, mad, they try to sing in their delirium, and their voice is now like the hissing of a snake, and now like the cavernous echo of a tomb. Look, now, at that horrible scene; some of these trunks, formerly men, now masses of rotten flesh, are possessed by libido-inexplebilis, and would like to indulge in pederasty and onanism with other not mutilated wretches, who having fallen into the opposite depravity, feel a horror for the sex, and all that refers to it; but who, devoured by insatiable hunger would like to eat their rotten arms."

Ulloa, in 1797, says: "Leprosy is rather frequent in hot climates; it is unknown in Peruvian highlands. The chief cause of the disease in Peruvian America has been the introduction of African negroes. Muniz mentions that Fray José de la Trinidad took charge in 1822 of the leper hospital which had been united with the incurables, in Lima, and was called del Refugio. With the exception of 1853, when nine persons succumbed to the disease, the average mortality from it was from two to six a year. The "long-bearded and small-cloaked father," as he was called, died in 1878. It is impossible, according to Muniz, to make a reliable statistic record of leprosy in Peru; the registers are few and insufficient. The decrease of the number of cases is a fact. Leprosy has been very hard on the black race. Almost all the ancient inmates were emancipated negroes. The disease affects Indians rarely. From 1870 to 1886, there died in the Refugio five men and five women; four of them Chinese.

Now considering that leprosy has become almost universal in Colombia, and that it has been almost extinguished in Peru, we are led to suppose that in the latter country great care was taken to isolate the lepers; for in no other way could that disease be extinguished. Therefore leprosy must have been rampant there. Such perfect isolation could only result from a great horror of the disease. And if such horror existed, would they be likely to bury with their dead the images of the horrible disease? It may be asserted that the influence of the Church isolated the lepers, so that no feeling of horror is necessary to explain their isolation. But the Incas never were under the influence of the Church, and the Church establishment existed in Colombia to as great an extent as in Peru.

I am inclined to believe that if these *huacos* potteries really represent disease manifestations, they must be of the syphilitic kind. To succumb to syphilis was to be the victim of a disease which was not at the disposition of the poor, who could not pay for the use of many women; and that use was considered as the cause of the disease. They had not in those ancient times any idea that a bacillus

must be the cause of the disturbance. Therefore to be buried as a syphilitic would probably be an honor, rather than otherwise, in the eyes of the general people, while to be buried as a leper would be quite a different affair. Hence we may conclude that if certain deformities are found in ancient burial places, it is more probable, at any rate, that they belong to syphilis rather than to leprosy.

In Saladoa, ancient Arizona, considerable pathologic evidence was found by Mr. Frank Hamilton Cushing of abscess of the lower jaw and perforation of the alveolar walls. In one case, part of the alveolus was lacking, giving to the jaw a very distorted appearance. Now these Saladoans have been considered by many archaeologists as allied to the Peruvians and the mound-builders of the Mississippi valley on account of their Inca bones. Such a deformation would be very similar to what we see in some specimens of *huacos* pottery; and it could be only syphilis, as leprosy has never any effect on the skull. The man could not distort the soft tissues of his jaw; the disease must be in the bone.

Mr. Bandelier, the explorer who sent to New York the *huacos* pottery which I have examined, has his headquarters on the Sacred Island of Lake Titicaca, 13,000 feet above the sea level. It was from this island that the original Inca descended to conquer and civilize the barbarous tribes of South America, and to found their capital, Cuzco, four centuries before the arrival of Pizarro, 1000 A. D. Now on these highlands syphilis had existed among the Aymaras and Quechuas many hundred years before the arrival of the Spaniards. Whatever evil these Incas brought along with them, was likely, according to all I have said before, to be syphilis.

In ancient Arizona, Mr. Frank Hamilton Cushing found some burial places which he calls extra-muros cemeteries, and he thinks they were for some kind of outcast people. It would be natural, especially for such persons who know something of the history of leprosy in Europe, to suspect that these places were leprous burial grounds. But he informs me that his examination of many hundred skeletons in the southwestern United States revealed no traces of leprosy among the prehistoric population of America. The importance of this statement consists in the special relationship more than plausibly supposed to have existed between ancient Peru and Arizona. One of the causes of this plausibility is the presence of llama, guanaco and vicuna representations in clays and in petroglyphs buried with the dead. That animal is supposed to have been extinct (by Mr. Bandelier) long previous to the sixteenth century. Another is the presence of *bolas* or sling stones, such as are now used in South America in the chase; the tombs furnished only the stones, the sling is only to be found in pictorial form. There are also the knotted cords found in sacrificial caves in the mountains surrounding Salado City, which resemble closely the *quipus* or sacred records of the Incas; these knots are the hieroglyphs, or the alphabet of those ancient tribes. There is, above all, the predominance among the Arizonians of the Inca bone.

Mr. Cushing states that he did not find in Los Muertos, one of these places of interment, either hair or cerements or anything that could have escaped destruction for a thousand years; he very naturally concludes from one thousand to two thousand years at least must have elapsed since those corpses were buried there.

The absence of any evidence of leprosy in Arizona will make the existence of the disease in pre-Columbian Peru very improbable.

(To be continued.)

## SOCIETY PROCEEDINGS.

### Medical Association of Georgia.

*Forty-sixth Annual Meeting, held in Savannah, April 17, 18 and 19, 1895.*

#### FIRST DAY—MORNING SESSION.

The Association convened at the Armory Hall at 10 A.M., and was called to order by the PRESIDENT, DR. WILLIS F. WESTMORELAND, of Atlanta.

Prayer was offered by the REV. DR. DRIPPS of the Independent Presbyterian Church.

Addresses of Welcome were delivered by MAYOR HERMAN MYERS and MR. J. F. B. BECKWITH, and DR. FRANK M. RIDLEY, of LaGrange, responded on behalf of the Association.

PRESIDENT WESTMORELAND then delivered his

#### ANNUAL ADDRESS

in which he said the Association was nearly half a century old, only a few of the original members remained with us, and each year we noticed that a loved face was absent and learned that an honored friend had passed from our midst to return no more. Within the lifetime of the Association, the history of medicine has been revised, the better part of surgery written, and every subject pertaining to medicine had widened out under the influence of broader ideas and the greater diffusion of knowledge—empiricism in medicine and surgery had almost disappeared, and that period when a great man's ideas, whether correct or not, was the standard he and his followers had for a guide, had passed away. Under modernizing influences scientific methods of research were carried out by trained observers in well-equipped laboratories in every civilized country, and under these careful and patient investigations the misty surroundings of the causation of disease had begun to clear. Medicine in its wonderful progress had outgrown the individual capacity of any one and had resulted in an elaborate division of labor and the permanent and beneficial establishment of specialism; able men by using their talent and genius along special lines, by their co-operative work had established the solid basis of the medicine and surgery of to-day. The specialists had to bear the brunt of a great deal of unjust criticism. In certain communities they had been censured as a class, when the blame was only merited by individuals. Unfortunately, there were medical men who used the broad cloak of specialism to cover the most outrageous charlatanism, and in this respect the field of gynecology presented more rank growths than any other.

A few years before the organization of the Association, in the upper portion of the State, there resided a country physician, a representative of that class of honest earnest workers, who from the vicissitudes of fortune had plucked the courage to endure and the inspiration to strive; a man surrounded by pains, care and anxiety; a man who ever proved a friend, comrade, counsellor and guide. This physician was Dr. Crawford W. Long, of Jefferson, Georgia, who by his discovery of anesthesia and his successful use of ether in an operation on March 30, 1842, revolutionized surgery and started it upon its most progressive era.

On motion, the Association adjourned to meet in the dancing hall of the De Soto Hotel at 2:30 P.M.

#### AFTERNOON SESSION.

DR. T. E. MITCHELL, of Columbus, contributed a paper entitled

TRAUMATIC WOUNDS OF THE EYE AND THEIR TREATMENT, which was read by DR. A. W. CALHOUN, in the absence of the author. For convenience of description, the author divided wounds of the eye into incised, punctured, lacerated, and contused wounds. Another classification would be into aseptic and septic wounds. So, likewise, we may have a simple, compound, or complicated wound. Simple, when the agent producing the wound and any other foreign substance carried by it into the rent is removed, and complicated when any foreign body, whether the missile inflicting

the wound or material carried by it remains in the injured member. The fundamental principles laid down for treatment of wounds in other parts of the body hold good here: 1, the arrest of hemorrhage. This will rarely be found troublesome; 2, mitigate any existing shock; 3, cleanse the wound of every vestige of foreign matter; 4, render the wound absolutely aseptic by thorough irrigation with an antiseptic solution—corrosive sublimate 1:2000-5000; 5, coaptation of the severed parts by sutures, if necessary; 6, antiseptic dressing; and 7, position and rest. The latter we accomplish with atropia or scopolamin, 2-5 grains to 1 ounce of water, and a light pressure bandage to control the movements of the lids. The author then referred to wounds of individual parts of the eye. Wounds of the conjunctiva alone are generally caused by some corroding agent, as acids or alkalis, and offer a favorable or unfavorable prognosis depending entirely on the extent of corneal involvement. Superficial wounds of the cornea are among the most frequent of accidents, and are caused by the deposition in its structure of small pieces of steel, emery, grains of sand, cinders from a railroad locomotive, etc.

As to those cases in which enucleation is indicated, no definite rule can be formulated, since the intelligence, occupation and situation of the patient from the surgeon must be taken into consideration. The object of excision is to remove the peril of sympathetic inflammation. It is fortunate that sympathetic irritation usually precedes sympathetic inflammation, and serves as a signal for immediate enucleation. A wound involving the integrity of the zone of danger, or one in which a foreign body remains in the eye, is the most prolific cause of sympathetic disturbances. The consensus of opinion of the best authorities is in accord with the observations of Deutschmann that sympathetic ophthalmitis is of bacterial origin, the microorganisms traveling by continuity of surface beneath the optic nerve sheath, by way of the optic chiasm from the offending eye to the sympathizing member.

The prognosis of sympathetic inflammation is very grave. The surgeon should not fail to so inform the patient, and if an attempt be made to save the offending eye it should be done only after a thorough understanding of the risk assumed as to sympathetic involvement. As a substitute for excision, evisceration and optico-ciliary neurotomy has been advocated and practiced by some; but the consensus of professional opinion still adheres to enucleation as the safest line of procedure.

DR. LOUIS H. JONES, of Atlanta, then read a paper entitled

#### URANALYSIS.

The author said that the rapid strides made in physiologic chemistry, and the more general use of the microscope, afforded us means for determining the composition of the urine with great accuracy, and a minimum amount of labor. No greater mistake can be made than to assume that the condition of the urine is an index to the state of the kidneys alone. Disorders of the brain, the liver, the heart, the stomach, alike tell their tale in altered conditions of the urine. The author discussed only the most reliable and simple methods of detecting such changes, and pointed out a few of the sources of error present in some of the methods in common use. There are, in making an examination of the urine, four points usually determined—namely, reaction, specific gravity, and the presence or absence of albumin and sugar. To these should always be added a knowledge of the amount passed in twenty-four hours, and the quantity of urea present, and where there is reason to suspect disease, or where the chemic analysis indicates it, the microscope should always complete the work. The reaction can be readily determined by means of litmus paper, the only point worthy of consideration being, in the event of an alkaline reaction, to know whether this represents the state of the blood, or whether it is due to fermentative changes, by means of which the urea has been split up with the formation of ammonium carbonate. Should this be the cause of an alkaline reaction, the litmus paper will regain its red color upon drying and warming. The urinometers in common use the author had found to be exceedingly unreliable, different instruments giving, with the same specimen, variations ranging from two to six points. The chemic tests generally made of the urine are a reproach alike to the chemist and the physician. What is to be desired are tests which are reliable under all ordinary conditions, which can be made without the consumption of too much time, and which require a minimum amount of skill for their proper performance. For the detection of albumin and for routine work, the essayist is partial to the ferrocyanide test, to the

exclusion of all others. It has to commend it, both simplicity and reliability. It is made by adding to, say, eight grams of urine, about six grams of a solution of potassium ferrocyanide (strength 1:20), and then adding one gram of acetic acid, when, if albumin be present, a distinct cloudiness will appear throughout the mixture.

The author called attention to the fact that often much unnecessary confusion is brought about by speaking of the percentage of albumin found in a given specimen of urine. As a matter of fact, the actual *weight percentage* of albumin present in urine never exceeds 3 to 4 per cent., and rarely exceeds 1 per cent., and yet it is common to hear of urines containing from 50 to 75 per cent. of albumin, reference being had to the bulk of the precipitate formed, usually with heat and nitric acid. This must necessarily depend much upon the time allowed for settling, and is wholly inaccurate and unscientific. The author then referred to the various methods for detecting sugar in the urine. In closing, he called attention to the centrifugal method of obtaining urinary sediment for microscopic examination. By means of a small electric motor, carrying two arms with tubes attached, and which can be run by a small battery, the urinary sediment may be obtained in a few minutes.

DR. A. W. CALHOUN, of Atlanta, read a paper entitled

#### THE MANAGEMENT OF HEMORRHAGE AFTER TONSIL OPERATIONS.

The frequency of alarmingly profuse hemorrhage after tonsil operations, with an occasionally fatal result, makes this a subject of exceeding interest to the surgeon. Such accidents should not, however, stand as obstacles in the way of performing these operations, for the necessity for them is both frequent and urgent. Especially in children is the enlarged or hypertrophied tonsil often met with, and the evil effects of the disease are so apparent to the medical and even non-medical observer, that it often calls for prompt action on the part of the physician. The ordinary hemorrhage following the operation is of but small consequence, as with a little patience and care the blood soon ceases to flow of its own accord; or, if need be, a gargle of cold salt water suffices to arrest it in the course of a few minutes. But when there flows from the cut surfaces a steady stream of blood continuing for hours, then it is that the tact and nerve and skill of the surgeon display themselves to the greatest advantage. With an experience of nearly four thousand tonsil operations, the author had seen but few cases of alarming hemorrhage in children. Young children are not very liable to dangerous hemorrhage, but it is in the adult that the great danger lies. The actual cautery applied directly to the bleeding surface, the author could not suggest; but he could recommend pressure directly applied to the wound, which is the most satisfactory of all means. Pass the forefinger, the end of which is covered with a piece of moistened sponge or absorbent cotton, into the mouth and carefully cover the cut surface, and with the wound between the forefinger of the one hand and the palm of the other hand placed externally, exercise gentle but steady pressure. The hemorrhage ceases immediately, but recurs upon the removal of the pressure. It is now a matter of courage and confidence on the part of the patient and of physical endurance on the part of the doctor. In most cases pressure continued for ten minutes to one or two hours suffices to permanently arrest the hemorrhage, but in rare instances it must be continued through twelve to twenty-four hours. In these last cases assistance must be called in, so that the persons exercising the pressure can be rested at intervals of half an hour. Dr. Calhoun has never known this mode of checking hemorrhage to fail, and he recommends it to any practitioner having such a case.

DR. R. J. NUNN, of Savannah, read a paper with the following caption:

#### SOMETHING NEW IN THE TREATMENT OF WOMEN AFTER CONFINEMENT.

It is well known that women living in a condition most nearly approaching to a state of nature do not require the "days of lying up" after confinement, nor do they keep them, as do the more civilized races, or the cultivated classes of society. The subject of the paper was a multipara who, after the birth of her first child, had suffered with prolapsus accompanied with cysto- and rectocele, continual backache, was generally puny, miserable and run down, at best a small weakly woman, but withal a most determined character, as will be seen later. One Sunday morning the patient was delivered and immediately expressed her determination of going to her work on the next day. No persuasion could change her resolution. Being a widow, she declared it to be a question of bread for herself and her children. Under

these circumstances it was determined to adopt the following method of treatment: twice daily the patient was to use a douche of a warm solution of boracic acid, immediately after which she was to report at Dr. Nunn's office. Here the uterus would be thoroughly cleaned out with aseptic water, and swabbed out with camphenodin (camphor, iodine and carbolic acid), the faradic current used with a vaginal electrode, a tampon applied, and an abdominal bandage was to be constantly worn. The treatment was carried out for about two weeks, after which it was gradually discontinued, and in about a month the patient was discharged apparently cured, not having had a single untoward symptom and declaring that her recovery had been better than after her first confinement, when she kept her bed ten days. Since this course of treatment, which is now several months ago, she has been continually at her work, not having missed a day. She enjoys better health than for years before and considers herself cured of her prolapsus.

As a guide to any one desiring to make further trial of this method of treatment, the author recapitulated the principles upon which it is founded: 1, thorough antisepsis; 2, effective internal and external support; 3, local stimulation to hasten involution of the uterus and the return of other overstrained parts to their normal condition; and 4, where necessary, the use of such appropriate general medication as may be indicated.

#### SECOND DAY—MORNING SESSION.

The first paper read at this session was by Dr. DUNBAR ROY, of Atlanta, entitled

##### THE PROPER CARE OF SCHOOL CHILDREN'S EYES—THE NECESSITY.

The author summed up the main points of his paper, as follows:

1. That the hygiene of school children's eyes should receive as much attention as that of any other portion of the body.
2. That in many cases where there is seeming physical ailment and mental inaptitude such as headaches, dull feelings, inattention, loss of the power of concentration, the cause can be found in some ocular defect.
3. That as myopia or near-sightedness increases as the pupil advances to higher grades, such treatment should be instituted as will arrest the progress of that pathologic condition.
4. That teachers should be instructed by competent ophthalmologists as to the hygiene of the eyes and the various symptoms which indicate some ocular defect.
5. That every child should have his or her eyes examined before entering school, and if necessary a certificate should be given to that effect.

Dr. FRANK M. RIDLEY, of La Grange, read a paper entitled

##### A DUTY OF THE STATE MEDICAL ASSOCIATION.

His remarks referred principally to the State Asylum, in which he said there had been dissatisfaction expressed as to the existing conditions and disappointment as to practical results. Most physicians were satisfied that inadequate legislative appropriations to a great extent lay at the bottom of these evils. According to the latest reports, there are at least 1,800 inmates in the asylum. So densely packed are these unfortunates that fresh applicants are frequently of necessity refused admission to the place, on the ground that it would be dangerous to allow the number of patients to increase. As a consequence, in a deplorable number of instances, filthy county jails, swarming with vermin and poorly furnished with beds and covering, are converted into temporary sanitariums for the treatment of the insane. Dr. Ridley urges that another scheme of investigation should be inaugurated, namely, let the Governor appoint a committee composed of seven of the ablest physicians to visit the asylum once a year, and not at stated times. Let them be clothed with full powers to make a searching sifting examination of every department from the kitchen to the superintendent's office. Submit to His Excellency a carefully prepared report to be transmitted by him to the legislative body, suggesting such improvements in sanitation and general conditions as may seem to them to be urgent and feasible. Let them urge greater attention to the moral treatment of the inmates, as may be suggested by expert study and investigation of the best systems of Europe and America. This will require some outlay of money. Money thus spent is well spent, and should be met by the funds of the State Treasury. Dr. Ridley then referred to the inadequacy of the medical staff to perform the vast amount of professional labor assigned it. For the medical treatment of the 1,800 inmates referred to, suffering a score or more of nervous ailments, there are not exceeding 5 on the medical

staff, a ratio of 600 patients to 1 physician, proportionally a greater charge on the physicians of the Georgia Insane Asylum than of any other similar institution, not only of the United States but of the world. Dr. Ridley, in closing, urged the Association to memorialize the Governor to co-operate with a committee from the Association, looking to the remediation of these conditions.

After a free discussion of this paper, the President appointed a committee of five to act upon the recommendations and suggestions contained therein.

Dr. J. M. HULL, of Augusta, contributed a paper entitled "Graves' Disease, with Cases."

Dr. W. S. ARMSTRONG, of Atlanta, followed with a paper entitled

##### REPORT OF SEVERAL INTERESTING OPERATIONS.

The first case was one of gastrostomy for impermeable stricture of the esophagus. The patient was 30 years of age and a printer by trade.

Case 2 was an interesting one, on account of the size of the stone removed from the bladder. In this case a supra-pubic operation was performed. The stone was of enormous size, elliptical in shape, flattened on two sides, and weighed at the time of removal thirteen and three-quarter ounces. Its greatest circumference was twelve inches, being larger by one-third than the stone removed by Dr. White, of Philadelphia, which has heretofore been regarded to be the largest stone successfully removed from a living person in the United States, without slough and without damaging the tissues. These stones compare as follows:

	Weight.	Circumference.
White's . . .	9½ ounces	8½ inches
Armstrong's .	13¾ ounces	12 inches, and 9¼ inches at right angles.

Patient recovered and now works on a farm.

Case 3 was one of operation for gun-shot wound of the abdomen.

Dr. F. W. McRAE, of Atlanta, read a paper entitled

APPENDICITIS—A BRIEF REVIEW OF MY PERSONAL EXPERIENCE, in which he said that in every case where there is a sudden attack of abdominal pain, especially if there be nausea and fever, appendicitis should be suspected and carefully sought for. In many cases it can be excluded, but it is always important to bear in mind the possibility of appendicitis and make a diagnosis at the earliest possible moment. Even in the beginning there are signs which point to appendicitis with more or less certainty. One of the first signs that may be observed is limited movement of the abdominal muscles of the right side during respiration. The four cardinal symptoms as laid down by Dr. Murphy are sudden attack of pain over the appendix; always nausea, frequently vomiting; elevation of temperature; exaggerated local tenderness in various positions occupied by the appendix should always be borne in mind. Occasionally the pain and tenderness has become localized on the opposite side of the abdomen or in the epigastric region. In some cases it is referred especially to the bladder, and the only symptom complained of is pain in the bladder, and either difficulty in emptying it or frequent urination. In two of the cases which the author had operated upon, this symptom had been especially well marked. In the atypical cases of appendicitis a positive diagnosis is often difficult, sometimes impossible, prior to opening the abdominal cavity. Except in the fulminant cases, the treatment should be medical in the beginning. The bowels should be thoroughly purged, the diet regulated, counter-irritation or cold applied over the seat of pain and tenderness, and the progress of the attack watched carefully. Where the symptoms do not subside after careful purging, and local treatment is indicated, the case should be considered from a surgical standpoint, and where the pain and tenderness are increasing and the general symptoms becoming more and more marked an operation should be done without delay, where favorable conditions and a good surgeon are at hand. Since the last meeting, the author had seen in his own practice, and in consultation, nine patients suffering with appendicitis, and two of them having had each two attacks. He had also seen one patient, referred to him by the patient's physician, who had treated him through several attacks of recurrent appendicitis in the intervals between the attacks. Of these ten patients he had operated on four, and assisted Dr. Nicolson in one, making five cases that had come to operation. Of the five cases operated upon, three of his, and the one operated upon by Dr. Nicolson, recovered. One of the cases operated upon by himself was an old man, who died nine

weeks after the operation from exhaustion and paresis of the bowels. Dr. McRae then gave histories of these cases.

#### SECOND DAY—AFTERNOON SESSION.

Dr. WM. O'DANIEL, of Bullards, read a paper (by title) entitled "The Hygiene of Prison Camps in Georgia."

Dr. VIROIL O. HARDON, of Atlanta, read a paper on

#### LAPAROTOMY DURING PREGNANCY.

It is comparatively seldom that the surgeon is called upon to open the abdomen of a woman who is normally pregnant. When conditions present themselves which would justify such a procedure in the non-pregnant woman, the existence of pregnancy offers a complication which leads us to consider seriously whether the interests of the patient would not be better served by postponing the operation until after confinement. There is always present a fear of interruption of the process of gestation involving a sacrifice of the life of the child in an effort to save that of the mother. Many cases therefore which would otherwise be legitimate subjects for abdominal section can no longer be so regarded when two lives are at stake instead of one. Urgent symptoms threatening one or the other of these lives constitute the sole indication for surgical interference under such circumstances. The altered conditions imposed upon the pelvic organs by pregnancy give a new and entirely different aspect to many diseases. The physiologic engorgement and the rapid structural changes which accompany pregnancy give to such diseases a different clinical history, and must be taken into consideration in discussing the prognosis and the treatment. The rapid development of tissue, most notably in the womb, but present also in other organs, extends to the new growths in these organs and causes rapidity of development of pathologic processes proportionate to the rapid development of normal tissue. This fact must always be borne in mind as a factor in the prognosis. Another question to be seriously considered in such cases is the effect which the diseased condition will have upon the development of the fetus in utero. Still another point to be considered is the effect which the operation itself will have upon the continuance of pregnancy. Experience has proved that operations for the removal of the ovaries and tubes and even pedunculated subperitoneal fibromas are not incompatible with the continuance of pregnancy. It has been shown that such operations not only do not produce miscarriage, but that they have no effect upon the subsequent development of the fetus. Probably the most frequent pathologic condition that we are called upon to consider in this connection is that of fibroma of the uterus. The technique of laparotomy upon the pregnant woman differs in no material respect from that of ordinary operations. Dr. Hardon then reported two interesting cases in which he had opened the abdomen during pregnancy.

Dr. JAMES H. SHORTER, of Macon, read a paper on

#### PREVENTABLE BLINDNESS, ESPECIALLY AS RELATED TO SYMPATHETIC OPHTHALMIA, WITH REPORT OF SOME TYPICAL CASES.

The author stated that most writers and all text-books divide sympathetic affections of the eye into two classes—sympathetic irritation and sympathetic inflammation. Some observers hold that the conditions are two distinct phenomena; that sympathetic irritation is a functional trouble, a reflex phenomenon, brought about through the agency of the ciliary nerves; while sympathetic inflammation is an organic affection, a genuine irido-cyclitis from the start, set up probably by a transference of sepsis by way of the optic nerves. The fact that in sympathetic irritation so-called, the removal of the injured eye procures immediate and permanent relief from all symptoms of annoyance in the fellow eye; whereas in genuine sympathetic inflammation such operation exerts but little, if any, influence in arresting the course of the disease, adds much probability to the truth of this theory. The author then dwelt upon the symptoms of sympathetic ophthalmia.

The treatment of sympathetic inflammation is chiefly anti-phlogistic; rest in bed in a dark room, hot applications, leeches, atropin, etc., but any and all treatment promises at best but little when once the affection has declared itself. Prophylactic treatment, on the other hand, is always infallible, and may be summed up in a few words—remove the injured eye, and to this may be added the further advice; do this in good time, at once if possible. The essayist briefly alluded to one case which from the sudden onset of the sympathetic inflammation, its destructive course in spite of early recognition of the condition and intelligent vigorous treatment resorted to, was a typical example and illustrated also

the probable futility of all remedial efforts. The author laid down as an invariable rule that every eye made totally or partially blind by a penetrating wound, and especially if the globe remains tender to touch, should be removed without delay. Even if there be some reasonable amount of sight still left in the wounded eye, this is not a contra-indication for the operation, for it may be set down as almost a certainty that a severely injured eye in which attacks of inflammation recur will be sooner or later lost.

Dr. WM. PERRIN NICOLSON, of Atlanta, made some remarks on

#### LIGATION OF THE EXTERNAL CAROTID ARTERY AS A PRELIMINARY TO AND COINCIDENT WITH OPERATIONS UPON THE JAWS.

He stated that in the history of ligation of arteries, the external carotid artery had stood for a long time as a vessel that could not be interfered with, but that Dr. Wyeth had concluded from his investigations on the subject that ligation of this vessel was feasible. Dr. Wyeth's work on surgery contains a full account and description of the normal anatomy of the vessel, its several variations, and the steps necessary to close it. The important feature about operations upon the external carotid is that in any trouble involving the external structures, in the face, about the mouth, etc., we can entirely cut off the circulation without interfering with the circulation in the brain, which has always caused a large mortality in the ligation of the common carotid. Some years ago, in an operation for removal of the upper jaw, Dr. Nicolson concluded to try the ligation of this vessel with a view to lessening hemorrhage at the time of the operation, and more especially in lessening the danger of return of the disease by a process of starvation, cutting off the blood supply from the seat of the growth. Since that time he had made the operation four times, always coincident with operations for the removal of the jaw, and more especially in connection with operations for malignant disease. He has no untoward circumstances connected with the four operations which he has made, and he feels certain that there is a wide field of usefulness ahead of this operation when it becomes more generally adopted, because the vessel is one which is easily reached and there can be no danger to the patient if the work is properly performed.

#### SCOPOLAMIN AS A MYDRIATIC IN COMPARISON WITH ATROPIN AND HOMATROPIN—A POSTSCRIPT TO A PREVIOUS PAPER.

This was the title of a paper contributed by Dr. ARTHUR G. HOBBS, of Atlanta. Scopolamin hydrobromate has been demonstrated to have some superior qualities as a mydriatic: 1, in the small dose necessary; 2, in the few minutes required to produce complete paralysis of accommodation; and 3, in the comparatively short time of its continuance. The author had used it in his refraction room almost exclusively in cases where atropin was not particularly indicated. The strength of the solutions has varied from .5 to .12½ per cent., and in the latter weak solution he finds that a complete mydriasis is accomplished as effectually and it seems as rapidly as when the forty times stronger solution is instilled. While he has, as a rule, used a .2 to a .1 per cent. strength, he does not believe that in these stronger solutions the result has been either more certain or has been accomplished in a shorter time. By all the comparative tests the weaker solutions have given quite as good results as the stronger, and in both the results have appeared to be the same as when atropin or homatropin has been depended upon as the mydriatic. In the few cases of glaucoma in which he could risk so powerful a mydriatic, no increase of tension was manifested. He does not doubt that we will find the results of the 1-160 per cent. solution, which he is now testing, will prove effectual. If so, when it is remembered that we use only from four to six drops from the pipette, the great potency of this drug is almost without a parallel. The author is using it in iritis when atropin does not promptly dilate; also in some forms of keratitis with increased confidence.

#### SECOND DAY—AFTERNOON SESSION.

Dr. J. C. LEHARDY, of Savannah, read a paper entitled "The Use of the Galvanic Current in Office Practice," in which he reported several interesting cases treated by this current with gratifying results.

#### REPORT OF A PART OF MY SURGICAL WORK FOR THE SIX MONTHS ENDING APRIL 15, WITH REMARKS.

This paper was read by Dr. J. B. S. HOLMES, of Atlanta. The author reports fifty-one cases. In no case had an ovariectomy been performed simply for the relief of nervous or reflex symptoms. He had operated only for diseased conditions that he knew could only be relieved by surgical pro-

cedure, and careful examination, post-operative, had confirmed his opinion in every instance. While he believes in conservative measures, the most radical are often the most conservative. He is ready to admit that the abdominal cavity had often been ruthlessly invaded and organs removed that should not have been touched. They had been removed for nervous symptoms due entirely to other causes, and for which they were in nowise responsible. On the other hand, tinkering gynecology was responsible for many diseased tubes and ovaries that could only be cured by removal. The introduction of various caustic remedies into the uterus caused destruction and sloughing of the mucous membrane, with a cervical canal in many cases previously constricted and so rendered by the applications that the decomposing masses could not pass out. What follows? A septic endometritis, which soon extends to the tubes and ovaries, producing trouble that nothing but the knife will relieve. This must be resorted to or the poor woman is frequently doomed to permanent invalidism, condition sometimes worse than death. Many of the cases that the surgeon is censured for using the knife upon are caused by such treatment. He does not condemn all local treatment; when properly directed, he believes there are many conditions where it is not only admissible but demanded. He does not wish to be understood as advocating the removal of every diseased ovary. Far from it. He declines operation in many cases where the patient is anxious for it. He tries to be conscientious and operates only where the disease is so advanced that it has or is likely to render the woman an invalid, and is incurable by any other means. The author's experience with catgut as sutures or ligatures has been unsatisfactory. He never uses it except when he does a trachelorrhaphy and perineorrhaphy at the same sitting. It is hard to sterilize, is soft, slips easy, is hard to tie with any assurance of safety, and is absorbed too quickly. While he had always deprecated the use of opium in abdominal work, he had used it with great care and caution. Increasing experience convinces him that those cases in which it is not given at all do much better and their convalescence is more satisfactory in every respect. Where the pain is so intense and threatens to exhaust the patient from continued suffering, he thinks it advisable to use opium moderately and with great care.

At the conclusion of the paper, Dr. Holmes exhibited a few specimens removed from women who had been the victims from one to three years of the so-called conservative treatment with iodine, iodized phenol, nitrate of silver, nitric acid, carbolic acid, and other similar caustics.

Dr. T. M. GREENWOOD, of Mineral Bluff, read a paper on

#### OBSTETRICS AS PRACTICED IN THE MOUNTAINS OF NORTH GEORGIA.

The author said that a prominent laparotomist of the South stated that healthy mothers were gradually "playing out," but thinks his observation was largely confined to the cities. Their habits before puberty are all that nature requires—plenty of pure fresh air, bodily exercise, as necessitated by their daily avocations; clothing loose and suspended from the shoulders; diet plain and simple but nutritious and plentiful. In girlhood they roam the fields and forests as boys, vieing with them in strength and surpassing them in many instances in the athletic sports; when suddenly puberty arrives, a change comes to them almost imperceptibly, and they are women, and very soon afterward become mothers. Of the 100 nullipara which the author had attended in labor and noted the age, 75 of them were 18 years of age and under, the youngest being thirteen years and two months. He had heard of a case a little over 11 years of age. They were all normal labors and made good recoveries.

Owing to lack of time, several papers were read by title and referred to the Committee on Publication.

The following officers were elected:

President, Frank M. Ridley, of La Grange; First Vice-President, W. H. Doughty, of Augusta; Second Vice-President, M. L. Boyd, of Savannah; Secretary, R. H. Taylor, of Griffin; Treasurer, E. C. Goodrich, of Augusta.

On motion, the Association adjourned to meet in Augusta the third Wednesday in April, 1896.

After adjournment, the Association enjoyed a steamboat excursion down the Savannah River to the Atlantic Ocean, and partook of an "oyster roast" on Wilmington Island.

#### American Electro-Therapeutic Association.

*Fourth Annual Meeting held in New York Academy of Medicine, New York, Sept. 25, 26, and 27, 1894.*

WILLIAM J. HERDMAN, M.D., President.

(Continued from page 640.)

#### AFTERNOON SESSION.

The meeting was called to order by the President at 2:30 P.M. Report of the Committee on

STANDARD ELECTRO-STATIC OR INFLUENCE MACHINES, by Dr. WILLIAM JAMES MORTON, Chairman.

The Committee would add to the recommendation of last year that the minimum size of machine should consist of six revolving discs of glass of at least twenty-eight inches in diameter, instead of four discs as then recommended; and recommend the *a*, inclosing case; *b*, separate exciting machine within the case; *c*, any convenient arrangement of parts to produce the static induced current. All these recommendations are now well established in practice.

Dr. W. J. MORTON read a paper on

#### ELECTRIC MEDICAMENTAL DIFFUSION.

METALLIC ELECTROLYSIS—CATAPHORESIS—SOLUBLE METALLIC ELECTRODES WITH ILLUSTRATIVE CASES OF TINNITUS AURIS, TRACHOMA, NASAL AND POST-NASAL CATARRH, URETHRITIS, TONSILLITIS, VASCULAR TUMOR, DERMOID CYST, NÆVI, SYCOSIS, ETC.

It often happens in medicine that a new method of procedure makes its way to success by a series of steps not seemingly related to each other in time or relevancy. This observation seems to me to be true of a number of individual therapeutic procedures which during recent years have been brought to the attention, particularly, of those interested in applying electricity to the cure of disease. Reaching back to the time of Fabré-Palaprat in 1833 (introduction of iodid of potassium through the skin), including the success of Benjamin Richardson in 1859 (voltaic narcotism) and culminating in recent years in the practical applications of Peterson, the writer and others (electro-cocain anesthesia, etc.), the term cataphoresis has sufficed both to name and to explain the practical facts. By aid of this principle of cataphoresis, fluids of the human tissue may be moved about, particularly in parts free from active blood circulation, from the positive to the negative pole, or medicine held in solution at a positive pole may be caused to penetrate the skin or mucous membrane at the site of that pole. The practice is equally available whether the polar electrode be the usual small one, or be a large one, as in the case of the water of an electric bath. And not only may medicines be thus introduced (as demonstrated by an examination of the urine) but they may also be removed from the human system (as demonstrated by using a bright copper plate electrode for the negative pole in the bath and finding a removed metallic deposited upon the copper). So far as relates to the introduction or the removal of medicinal substances, I have termed the process cataphoric medication and cataphoric demedication. I have also established a method useful in gouty and rheumatic joints and in other conditions of cutting off the blood supply by rubber rings or by an Esmarch's bandage and thus affording the medicine introduced greater facility to act upon the affected tissue. This process I have termed anemic cataphoric medication. Turning to another set of the isolated phenomena, which I am about to suggest may be included under one general caption and nomenclature, we are confronted with that great and fundamental principle of electrolysis without which there would be no conduction of electricity in the human tissue, and yet so diverse are its exhibitions according to the strength of the current, according to the actual decomposition of the tissue or its non-evident decomposition, and according to the fluids in solution at the poles of the applied electrode or the nature of the electrode itself when introduced within the tissue, that confusion reigns as to specific effects and methods.

Involved in this principle of electrolysis and the introduction of medicamental substances into tissue, there are a great variety of special processes as, for instance, cataphoric medication already alluded to, and furthermore, processes where the electrode itself furnishes by electrolysis of its own substance the new medicine introduced (soluble electrodes) or where an insoluble electrode conveys the current which decomposes a fluid introduced within the cavity to be treated. The two latter methods are known as the "interstitial electrolysis" of Gautier, or in the case of the soluble

Blank Applications for membership in the Association at the JOURNAL office.

electrode as "metallic interstitial electrolysis" of the same author. The simple fact which arises out of this confusion is that the electric current causes a diffusion of the medicines into and throughout the tissue.

It matters not whether the medicine in solution be applied by a sponge or blotting paper against the skin (cataphoric medication), be held in solution in the water of an electric bath (again cataphoric medication), be injected into a cavity and decomposed (interstitial electrolysis), be dissolved by the action of a current off of a needle perforating the tissue (metallic electrolysis), or be dissolved from an electrode held in contact with mucous membrane (also metallic electrolysis); the result is the same—a foreign substance in solution, viz., a medicine is caused to enter and permeate the tissue. It therefore seems to me to be a proper time to generalize the entire facts under the term of electric diffusion of medicines into human tissue or, simply, *electric medicament diffusion*.

To secure this diffusion it is only necessary that the artificial and applied electrolyte (the medicine or substance in solution) be caused to constitute a part of the electrolyte into which it is to be diffused and then the general principles of both electrolysis and cataphoresis come into play; the various ions are redistributed or diffused according to well-known laws, while also, equally, the principle of cataphoresis is at work whereby irrespective of ionic distribution, fluids are moved from the positive to the negative pole or sometimes *vice versa*. This diffusive property of the current, taken advantage of in connection with human tissue, opens out to electro-therapy and general medicine an immense and a fascinating field of study and practice, and in many important directions points out entirely new treatments of a great variety of diseases thus far not commonly treated in this manner. The field is so broad a one that I will confine myself in this communication to the electric diffusion of metallic salts, one form of the interstitial electrolysis of Gautier.

#### ELECTRIC DIFFUSION FROM SOLUBLE ELECTRODES.

The destructive electrolytic action in human tissue of either pole of a continuous electric current is perfectly familiar. The electrodes are usually of metal, and care is taken that they be unoxidizable, as is, for instance, platinum or gold, if they are to be used at a positive pole, while, if used at the negative pole, they may be oxidizable or not. The positive pole electrode, when the current is in action, forms oxygen and acids out of the tissue itself; the acids are mainly hydrochloric, sulphuric and phosphoric. The negative pole forms hydrogen and alkalis, the latter usually caustic soda and potash. Each pole is practically a little chemic workshop by itself—the one acid, the other alkaline; the analytic and synthetic energy being furnished by the electric current and the materials acted upon being furnished by the tissue. The resultant and desired destruction of tissue is due to a number of factors, chief among which are that amount of tissue used to make up the newly formed and foreign chemicals, the secondary action of these newly formed products upon the remaining tissue, and the disruptive effects upon the structural composition of the tissue of the gases interstitially liberated. And the character of the artificially produced lesion and its resultant eschar is determined, to a great extent, by the second of these actions, whether it has been an acid or an alkaline corrosion or destruction. The lesion resulting at the negative pole is rich in fluids (by cataphoresis), and is slower to heal; it leaves, however, a smoother and less contractile cicatrix (an important consideration in the removal of facial blemishes). The lesion resulting at the positive pole is comparatively dry (also by cataphoresis), is quicker to heal and leaves a rougher and more contractile scar.

It will be observed that in this, the familiar form of electrolysis, no account is taken of the nature of the active electrode employed except that it be unoxidizable, insoluble, and therefore indestructible, and that as a consequence reliance for the electrolytic effect is based directly upon the characteristic effect of the current upon the tissue and not upon its effect upon the electrode. Any action of the current upon the electrode is, in fact, carefully guarded against.

But if we turn our attention to the nature of the metal which composes the electrode, be it the positive or (as I have demonstrated) the negative, an entirely new field of investigation and of results is opened out to our view. If our positive electrode be composed of a metal which is attacked by oxygen or by chlorine (formed at that pole out of the tissue), then a new chemic compound is formed at the point of the application, and we have no longer to deal with the effect of the liberated chemicals directly upon the tissue,

but we are confronted with a new effect, viz., that of the newly formed chemic compounds (metallic salts) upon the tissue. And since, owing to the nature of human tissue, hydrochloric acid is pre-eminently formed at the positive pole, we shall find if copper, zinc, iron or other attackable metal is the metal employed at that pole, that we have formed respectively the oxychlorides of copper, zinc, iron, etc., double salts of the metal.

In this connection we may observe the further interesting fact that under the above circumstances the action of the current is almost entirely expended in decomposing the metal, and that as a consequence the undesirable destructive action of the usual electrolysis is avoided. For, as I have observed in practice and as will be seen upon reference to the cases in which this method of treatment is applicable and peculiarly efficacious, the destructive action of the current would be in the highest degree detrimental. The object is not to destroy tissue, as by actual cautery or by the application of caustics, but to implant within it and permeate it with the newly formed metallic salt. In fact, so distinctive is this new method, which is termed by Gautier, its modern author, interstitial electrolysis, from common surgical electrolysis, that it is unfortunate to use the term, electrolysis, at all in relation to it. The electrolysis is, as has been pointed out, principally of the metal, and but to a very limited extent of the tissue. A far more characteristic feature of the process is that the product of the electrolyzed metal permeates tissue, and it is for that reason that I feel compelled, in speaking of the method, to designate it as electric diffusion.

Another noticeable feature of electric diffusion of salts formed from soluble electrodes is that a remarkably low current strength suffices to set free a large amount of the metallic salt. Here, again, is a reason that very little of the usual electrolytic destruction of tissue ensues. Gautier, indeed, calls attention to this fact, and characterizes this method in its gynecologic applications as one of low current strength and long sittings, in contra-distinction to the Apostoli method of high current strength and short sittings. In practical work, I have found that very low current strength, from 1 to 10 milliamperes, gives much better results than from 10 to 50 milliamperes. In this connection it should be noted that the electrode loses in weight. Gautier has found, as would be expected, that the loss in weight is proportional to the current strength and the duration of the current flow.

Again, the solution of the metallic electrode is not confined, as thus far supposed, to the positive electrode alone. I have found by experiment that soluble electrodes may also be employed at the negative pole. One of the best of the metals for this purpose is aluminium. The extension of metallic electrolysis to the negative pole greatly widens the field of this new method, since, while at the positive pole we have thus far been confined to the oxychlorides of metals we now at the negative pole may apply to diseased tissue another class of metallic salts.

Electric diffusion, as the word, diffusion, indicates, possesses an obvious advantage over the ordinary topical applications of similar or other metallic salts of copper, zinc, iron, aluminium or other metals. For it is obvious that not only is the salt dissolved off of the metal, but by another and further property of the current it is forced into the tissue in a radiating direction around the metallic electrode. In this respect, electric diffusion is remarkably unlike the application of the ordinary solutions by a brush, spray or injection, or their injection into tissue by the hypodermic needle. The solution of the salt is not only applied but it is driven in. To use a homely simile, a wash or spray is like a nail held against a board, while electric diffusion plays the part of the hammer which drives the nail home.

#### HISTORICAL—ELECTRODES—TECHNIQUE—CASES—CONCLUSIONS.

The dissolving action of the electric current upon a metallic electrode, constituting a positive pole and applied within human tissue, had been noted by various authors in relation to the treatment of some diseases, particularly tumors, by electrolysis. Both Butler and Stevenson and Jones refer to this action upon zinc needles and point out the conjoint efficacy of the combined destructive action of the current and the newly formed chlorid of zinc.

Onimus, of Paris, and Prochownick, of Hamburg, appear to have casually used soluble electrodes at the positive pole. The latter applied a copper sound with a current strength of from 80 to 100 milliamperes in a case of gonorrheal infection of the uterine cervical canal.

But these isolated observations made almost no impression upon practice, and it remained for Dr. Georges Gautier,

of Paris, to grasp the broad idea of diffusing metallic salts from soluble electrodes and to inaugurate by a series of experiments this new system of procedure.<sup>1</sup>

At once appreciating the far-reaching merits of the new method, I established its use in a great variety of cases in my clinic at the New York Post-Graduate Medical School and Hospital as early as 1891, and also at the same time in private practice. The method was taught to matriculates by actual demonstrations. Experiments were made of its effects in trachoma, hypertrophic nasal catarrh and ozena, gonorrhea, keloid, and continued, in a great variety of diseases, and with a variety of metals at the positive pole. Obviously, the method once understood implies its application to a large number of cases and by any soluble metal. Papers and contributions to journals and societies have been published by my clinical assistants detailing my work and instruments and by Dr. Clarence C. Rice, of New York City.

FIG. 1.—"Soluble" Needles.

FIG. 2.—"Soluble" Bulbs.

FIG. 3.—"Soluble" Bulbs.

FIG. 4.—Protected Soluble Electrodes.

**Electrodes.**—Successive applications to diverse morbid conditions continually suggested new electrodes suited to the individual classes of disease. These have been made as occasion arose by the Galvano-Faradic Manufacturing Company, of New York City, and may be bought of them.

**Needles,** Fig. 1. These are manufactured of any desired metal. I use, preferably, copper, zinc and iron at the positive pole and aluminium at the negative. About 1 millimeter in diameter and 8 centimeters in length form a convenient size. Insulated material restricts the action of the current to the locality desired to be affected and prevents action upon the sound skin. They fit an ordinary needle holder.

**Bulbs,**—Figs. 2 and 3. Like the needles these are manufactured of a variety of metals. For convenience they are constructed in sizes of the French catheter scale, each bulb capable of being attached by a screw thread to a universal handle. The sets resemble those known as Dr. Fry's, and were first made of copper by Dr. A. H. Goelet.

An important modification of the bulb (Fig. 4), devised by the writer more than a year ago, is to divide it longitudinally into one-half metal and the other half ebonite, thus affording a protected and an active side of the electrode,

for it often happens as in the rectum, urethral canal, cervical canal and other canals, sinuses or cavities, and in trachoma that it is undesirable at a single treatment to attack approximating surfaces; again, it may be desired to protect a given surface.

The handle curved at right angles is used in the post-nasal cavities. The metal may be bent to any desired angle; its tip is insulated and an insulating sheath exposes any desired area for active effect.

Obviously, electrodes for special cases will suggest themselves, and types familiar in form will be constructed of soluble metals as occasion demands.

**Technique.**—I have already expressed a preference based upon much experience, for low current strength and prolonged time. It is difficult to lay down rules which shall apply in so many diverse diseases. In needle puncture (copper or zinc needles) I prefer to use no more than 2 milliamperes applied at any one site for about three to five minutes. In a case of sycosis, reported later on this was quite suffi-

FIG. 5.—Writer's Protected Electrode and Handle.

FIG. 6.—"Soluble" Bulbs Attached to Handles.

FIG. 7.—Protected Sound of "Soluble" Metal, Copper, Zinc, Iron, etc.

FIG. 8.—Writer's Protected Nasal Electrode.

cient to cure the disease. In lupus, ulcerations, pustules and acne this is also quite enough current strength. Gautier reports using 50 milliamperes in a case of lupus, but I have found the high current strength seriously objectionable because of the consequent electrolysis of tissue and extension of the time of healing. In hypertrophic nasal catarrh with copper bulbs, I find about 4 to 8 milliamperes sufficient. In ozena the same; in trachoma 1 to 2 milliamperes and in intra-uterine applications from 10 to 20 milliamperes; in gonorrhea 1 to 2 milliamperes.

No positive rule can be laid down, since much depends upon the size of the electrode. In order to facilitate accuracy of dosage, I employ copper bulbs graduated according to the French scale of catheter or other electrodes whose surface area is a known quantity.

The operator may convince himself, if he desires, of the great rapidity of the electric diffusion of the copper salt by sticking the needle lightly into his own skin, or that of a patient, and watching the almost immediate formation of a small circular area of an apple green color. This is also well

<sup>1</sup> Revue Internationale d'Electrothérapie, July, 1891, August and September, 1892. Also Technique d'Electrothérapie, by Drs. Gautier and Larat.

seen in a small wart or similar growth; the mass turns light green. Or the copper needle may be inserted into the white of a "hard boiled egg" or into a piece of meat, and the same rapid formation and diffusion of the copper salt be noted.

A practical point of importance is to thoroughly polish each electrode immediately before using it. This is easily accomplished by the aid of a piece of fine emery paper.

The adherence of the electrode to the tissue is a peculiarity and a danger. Even with a current strength of from 2 to 4 milliampères this adherence is noticeable. Therefore even when low current strength is employed as during the application of smooth metallic surfaces to mucous membrane as in nasal and throat diseases, in trachoma, urethritis, etc., the electrode should be kept in slow movement, either longitudinal or rotatory. In the case of needles plunged into tumors and of sounds within the uterus this adherence can not be overcome by any safe manipulation; the needle must be loosened by reversing the polarity and using from 4 to 8 milliampères for about five minutes. The adhesion is due to the formation of an albuminoid salt of copper (where the electrode is of copper).

An operative outfit consists of any good galvanic battery, a water rheostat, a sensitive galvanometer needle and appropriate electrodes.

*Cases.*—I present the records of a few illustrative cases. It is needless to say that much has been learned as to technique, precision and efficacy in securing results in individual diseases since my first cases were recorded. Certain cases of lupus, cancer, etc., now under treatment are reserved until sufficient time has elapsed to enable a mature opinion to be given as to results.

#### CHRONIC TINNITUS AURIUM.

Probably there are few minor troubles more annoying to the patient than a chronic ringing in the ears; certainly there is no minor condition more difficult of cure. The cases as I have seen them are often associated with some degree of catarrhal trouble and commonly with tympanic vertigo and moderate deafness.

*Case 1.*—H. E., age 33; cured. Referred to me March, 1893, by Prof. D. B. St. John Roosa, to relieve him, if possible, of a most annoying and persistent ringing in both ears. Five years ago had a "dry throat;" had little saliva; mucous membranes cracked and bled; was treated by sprays for two years with no benefit; then used antiseptic washes. The uvula was elongated and had been cut off. Throat never ceased to trouble him. Two years ago had the grip, and about this time the ringing began. Present condition: weary, "nervous," depressed and irritable with much frontal headache and an almost continual ringing, worse in the left ear. The sound is like that of a distant cricket or like a sharp whistle; it worries him most when he is tired or when he lies down or after sexual intercourse. Sleep is often disturbed because he can not get rid of the sound in his ears. As a rule it is worse at night. Has likewise much post-nasal discharge. Hearing in left ear considerably impaired; has some vertigo. The first treatment to the ears and throat was by the static induced current, then the sinusoidal, both followed by amelioration in the degree of the sound and by intervals when it ceased for a few hours. But the progress was not satisfactory to me and I determined to treat the catarrhal condition first and cure it, before following up further applications to the aural region alone.

March 29. Electric diffusion, copper bulb, throughout the post-nasal and pharyngeal region, 12 milliampères five minutes to each side.

March 31. Discharges from nose anteriorly and posteriorly almost *nil*; ringing about the same.

April 3. Ringing unimproved; headache better; slight nasal discharge. Repeated treatment.

April 4. Raises slightly thick discharge from throat; watery discharge from nose; ringing same as ever.

April 5. No discharge. Treatment repeated. Reports never felt so well for years, of the catarrhal symptoms. Ringing in ears ceased during the treatment.

April 7. Headache; ringing in ears worse; no nasal discharge. Treatment five minutes, 10 milliampères.

April 8. For a half hour after rising this morning was free from the ringing.

April 10. Ringing ceases for long periods; no nasal discharge.

April 13. Ringing continuous. Treatment same.

April 14. Ringing very slight; no headache; very little nasal discharge. Treatment, five minutes, 5 milliampères.

April 15. Much ringing in left ear.

April 19. Reports a discharge from the left nostril which

colored the pillow in the night; a good deal of catarrhal trouble; bright yellow discharge and intense headache, also that his hearing was not so good. Discontinued treatment at the patient's request.

May 3. Against the patient's desire I persevered with electric diffusion, applying the electrode freely to his hypertrophied tonsils and post-nasal region on the sixth, tenth and thirteenth. The ringing still persisted in a marked degree.

May 19. Ringing the same; vertigo. Treatment same.

May 25. Ringing and catarrhal troubles have ceased since last treatment. The throat presented an almost normal appearance; the narrowing and congestion of the fauces had disappeared; the tonsils were normal in size. One more treatment was given and the patient was allowed to cease, as nothing further remained to be accomplished. The treatment by electric diffusion from copper had occupied about two months and had been repeated about twelve times.

Jan. 30, 1894. Patient reports that he has had no further ringing in ears and remains well of it, in spite of an attack of the "grip" during the winter.

#### TRACHOMA.

With the pathology and histology of this disease we have here nothing to do. It is merely a question of causing the absorption of the sago-like granulations or elevations in the conjunctiva, with the relief of the associate symptoms of pain, lachrymation and in the acute varieties the mucus discharge. The classical treatment is by operative or medicinal measures. The former removes the granulations by squeezing out their contents; the latter attempts to cause absorption by setting up by various drugs a certain grade of inflammatory reaction. It is here proposed to treat this obdurate affection by another method, viz., the combined action of electricity and a nascent metallic salt caused to permeate the affected tissue by means of the diffusive property of the electric current. This method is very successful.

The use of electric diffusion in this disease first occurred to me in the case of an Italian woman under treatment for goitre at my clinic. The case briefly follows:

*Case 1.*—Jan. 4, 1892, R. P., age 50; trachoma, both lids of both eyes. Extreme photophobia; intense corneal vascularity; excessive lachrymation; trachomatous bodies ("sago grains"); impaired vision. Treatment, electric diffusion from a copper electrode. An impromptu electrode was formed by bending a piece of copper wire into a suitable U-shaped loop. The loop was then passed *slowly* over the affected surfaces of the lids, while at the same time a current of 2 milliampères was flowing. The reader is referred to later cases for more typical results, for the reason that the treatment was inadvertently substituted at times by the use of the negative pole. But the cornea cleared, the trachomatous bodies became greatly reduced in number, the photophobia was much less, no lachrymation; the vision improved; the patient could see better and was able to read. This case simply initiated a method which was afterward carried out with more care and greater detail in my clinic, by myself and my assistants.

Care in manipulation is requisite. The eyelid should be everted as is usual in applications of the sulphate of copper or alum pencils, or the special protected electrodes devised by myself (Fig. 4) may be employed, without everting the lids. The electrode should be kept very slowly in movement or it will adhere to the conjunctiva and cause slight laceration upon removal, or at least compel the operator to reverse the polarity. Any metal, soluble at either pole may be employed, but copper and zinc are undoubtedly the best. The electrode without current will cause pain and with current somewhat more pain. To annul the pain, cocaine may be used in the usual manner.

*Case 2.*—Acute trachoma, first stage. March 22, 1893, patient age 11, had purulent conjunctivitis; upper and lower lids of both eyes trachomatous. Treatment: Electric diffusion from copper electrode, 2 milliampères, one minute to each lid. After the first treatment the photophobia almost entirely ceased and the granules diminished in size. The patient received six applications and was cured. April 29, 1894, about a year later, reports that he had remained well.

*Case 3.*—July 21, 1893. P., age 21; trachoma second stage. Referred to the clinic by Dr. Francis Valk, of the Ophthalmological Department of the Post-Graduate Medical School. During one year had suffered severely from photophobia, lachrymation and pain. Extensive ulceration of cornea and lids highly trachomatous. Treatment: Electric diffusion from copper electrode, 3 milliampères. July 24, patient much better; no pain; swelling of lid and ptosis of right

eye much diminished. Less photophobia, soreness and lachrymation, trachomatous bodies very much softer and less gritty to contact of electrode. Electric diffusion from copper, 10 milliamperes from two to three minutes. July 26, edema of the lids has entirely disappeared; slight ptosis remains; no lachrymation; trachomatous bodies no longer isolated; cornea almost entirely clear. Same treatment. July 31, after the fourth treatment the trachomatous bodies had become entirely absorbed. Cornea perfectly clear. Dr. Valk stated that the result "was 50 per cent. better than he could have secured with the classical methods of treatment." Six more similar treatments completed the patient's cure, with the simple exception that some slight conjunctival redness remained as well as a moderate sensitiveness to bright sunlight. May 8, 1894, as the patient has never returned he presumably has remained cured.

*Case 4.*—July 21, 1893, A. D., age 8; trachoma, second stage. Purulent conjunctivitis with congestion and edema of the surrounding tissues; both upper and lower lids profusely covered with trachomatous bodies. Five treatments, electric diffusion from copper electrode, 3 to 7 milliamperes; cocaine. The first treatment was followed by diminution of the mucus discharge; of the pain, lachrymation and photophobia; the trachomatous bodies softened and were gradually absorbed. Cured.

*Case 5.*—August 30, 1893, W. T., age 16; granular lids for seven months; pain; stiffness of lids; photophobia; morning adherence of lids; electric diffusion from copper, 3 milliamperes. After twelve treatments, case cured by October 30. Applications were imperfectly made, owing to the refractory nature of the patient.

*Case 6.*—Jan. 15, 1894, K. S., age 17; native of Egypt; trachoma, third stage; always had weak eyes; began to be troublesome five years ago. Has photophobia, lachrymation, constant muco-purulent discharge and pain. Can only see as "through smoke." Palpebral conjunctiva scarred and white. Both lower lids, palpebral conjunctiva, adherent and dragging in the eyeball. Cicatricial conjunctivitis. Case "incurable." Treatment: Electric diffusion from zinc electrode, 5 milliamperes to conjunctivæ of both eyes. March 9, 1894, reports both eyes better; now sees clearly; lachrymation has ceased; lids are no longer glued together in the morning by the mucus discharge. Repeated diffusion from zinc, 3 milliamperes to lids of both eyes. March 23, 1894, adhesions between the conjunctiva and the eyeball at the left lower lid were treated with negative electrolysis, 1 milliampere. April 18, 1894, palpebral conjunctivæ have assumed a more normal appearance. Circulation improved; less induration; patient regards herself as very well.

*Case 7.*—March 23, 1894, M. B., age 11; acute trachoma, first stage. Lids edematous; conjunctivæ injected; lachrymation, upper and lower lids of both eyes trachomatous. Treatment: Electric diffusion from copper, 1 milliampere. March 26, noedema; conjunctivæ lessened; sago grains have disappeared; treatment same. March 28, 1894, much better; slight redness of conjunctivæ; no mucus discharge, pain or photophobia; eyes clear and bright, 3 milliamperes to both eyes. April 13, 1894, cured.

#### HYPERTROPHIC RHINITIS AND PHARYNGITIS.

The class of cases here referred to were of a chronic type and exhibited anterior and posterior nasal discharge, generally thick and purulent; the disturbed sensation of swallowing, due to retained secretions in the post-nasal space, narrowing of the rhino-pharynx and the characteristic symptoms of hypertrophy of the nasal and pharyngeal mucous membrane. Their treatment was carried out by electrodes of copper and zinc devised by the writer, see Figs. 3, 4 and 6, and by a method devised and taught by him to clinical assistants, among others to Dr. M. A. Cleaves, who has written a paper whose originality is derived substantially from the writer's teaching in this as in other branches of metallic electrolysis. Struck by the results obtainable in this disease by this method, I also called the attention of Dr. Clarence C. Rice of the Department of Laryngology, Post-Graduate Medical School, to these results and he has, he writes, made trial of the soluble metallic electrodes in a number of cases which he has reported at a meeting of the American Laryngological Association in Washington.

*Case 1.*—Nov. 27, 1891, B. M., age 15. Ozena. One year ago patient contracted an acute catarrhal cold; it continued a month; since then has had a chronic catarrhal condition of the nasal passages. Odor began four months ago. There is a greenish muco-purulent discharge from the nose, post-nasal droppings and a slight irritative cough. Treatment: Electric diffusion from copper electrode. As in the first

trial of this method in trachoma, so in this case the negative pole was also used. But experience soon taught me to confine the treatment to electric diffusion from the positive metallic electrode. By December 9, after four treatments the discharge was less, the odor less noticeable and the respiration freer.

January 8, examined by Dr. C. C. Rice who reports deviation of septum toward right; left nostril twice the width of the right; middle turbinated bones covered with dry scaly secretions; pharynx dry with hypertrophied ridges on the sides. Further treatment by diffusion from copper was carried on, 1 milliampere for ten minutes. January 15 and 18, 5 milliamperes each nostril, also same January 20, 22 and 27. Discharge diminished and less greenish. February 1, 3 and 5 same treatment. Patient though not cured is much better; less discharge, odor and headache. Improved.

With the present improvement in methods and electrodes I should expect to cure this patient should the opportunity present itself.

*Case 2.*—August 8, 1893, D. L. G., age 41, ozena; post-nasal catarrh, atrophic. Has always "taken cold" easily. Had catarrh at 13 years of age; at 18 it had increased a great deal and he began to use salt water and a great many other nasal douches and "went to a great many doctors." His sense of smell became much impaired nine years ago and has been growing worse ever since, until at present he cannot detect odors. The patient states, though I have had no opportunity of verifying his statement, that one year ago he had the antrum opened by Dr. Toeplitz, assistant to Dr. Knapp, and pus evacuated. This opening is still patent and must be plugged twice daily. Symptoms: Copious and most offensive anterior and post-nasal discharge; a great many crusts form; the nose bleeds easily; odor from patient's nose and mouth most offensive. Treatment: Electric diffusion from copper bulbs, Nos. 27 and 29 (Fig. 3) to naso-pharynx, 15 to 25 milliamperes, occupying about five minutes. August 11, same treatment. Pharynx very much less congested; more discharge; patient says he feels very much better. August 15 and 23, crusts free themselves more easily; increased discharge from nose and slight bleeding after douching; treatment same. August 30, patient reports that his condition is very greatly improved; the incrustations remarkably diminished; very much less discharge, and that morning for the first time in eight years the sense of smell had returned to him and he had smelled paint and once more enjoyed eating; there was no offensive odor. The patient expressed himself as "50 per cent. better," and stated that no other treatment had ever accomplished as much for him.

*Case 3.*—Oct. 21, 1892, A. R., age 9, profuse muco-purulent discharge from the nose; nasal and pharyngeal obstruction of one year's duration. Treatment: Electric diffusion from copper electrode, about five minutes in duration and with a current strength varying from 5 to 10 milliamperes. Symptoms began to improve at once and after fourteen treatments, each several days apart, the patient was cured.

*Case 4.*—April 5, 1893, F. A., age 20; hypertrophic rhinitis. Had diphtheria in November, 1891. Ever since has had severe catarrhal trouble in frontal sinuses and nasal passages, anterior and posterior. Profuse, thick, yellowish discharge and much dropping of the discharge posteriorly. Feeling of intense fullness across forehead; upper lip and anterior portions of nose reddened and excoriated. Treatment: Electric diffusion from copper electrodes in anterior and posterior nasal passages on the left side. April 12, discharge not nearly so profuse nor as yellow on the side treated; less redness about the nose and lip. Right side treated in same manner as left; 10 milliamperes for five minutes. Like many patients of this class he did not return and the case merely suffices to point out the immediately favorable effect of the first treatment.

*Case 5.*—Mrs. G. W. E., age 34, nasal catarrh, hypertrophic. Has had catarrh for three years with constant "dropping in back of throat," heaviness and dullness in head around eyes; used handkerchief constantly; good deal of nausea.

April 28. Electrolytic diffusion to left nostril. Positive pole, 3 milliamperes for fifteen minutes.

May 3. Feeling of heaviness in head in morning gone; no nausea; application made to left nostril 5 milliamperes, ten minutes; nose feels very much clearer; discomfort from application gone in half an hour.

May 5. Same treatment to both nostrils; is feeling a

NOTE.—Unfortunately, owing to unavoidable circumstances, this patient ceased treatment and has not since been heard from. It is to be regretted that the same treatment, as might easily be done, should not have been tried for the antrum.

good deal better; dropping in back of throat gone; scabbing in interior nostril does not occur, also diminution in amount of discharge.

May 9. Until yesterday felt well; has taken cold and amount of discharge has greatly increased; large scab in left nostril; this was treated locally.

May 15. Very much less discharge; 6 milliampères to each nostril.

June 24. About twelve treatments more of same strength; application also made to pharynx and naso-pharynx, about 10 milliampères. Is very much better and is troubled but little. Went away on vacation at this time and the last of September returned feeling well and nasal symptoms entirely relieved. Cured.

*Case 6.*—Miss H. J., age 48; post-nasal catarrh. About fifteen years ago affection began in left side; had ringing in ears and heavy cold; since has had constant buzzing on that side; ticking of watch not heard; right ear normal. Is not particularly susceptible to colds; hearing is worse with a "cold;" no pain; has dropping of secretions into throat. Appearances, left side, pharynx atrophic; right side, pharynx hypertrophic; soft palate and entire isthmus dusky red. Treatment: Electrolytic diffusion 10 milliampères, applied positive pole about six minutes all over pharynx, also through left nares 10 milliampères five minutes. For a few minutes the amount used was 20 milliampères. Cured.

#### FOLLICULAR TONSILLITIS.

*Case 1.*—Oct. 18, 1893, B. G. A., age 15, throat began to be sore two days previously; painful and swollen; sense of malaise and nausea; tonsils enlarged and grayish-white spots on both. Treatment: Electric diffusion from copper electrode to every spot.

October 20. No more trouble with throat. Tonsils normal in appearance except for slight increase in their normal redness.

*Case 2.*—Jan. 18, 1894, F. D., aged 18; shivering and hot flushes, malaise; temperature 100; grayish-white spots on tonsil. Treatment: Electric diffusion from copper, 10 milliampères to every follicle as well as over entire tonsil. January 17. Patient reports that the throat was entirely relieved the next morning and to-day feels entirely well. Tonsils about normal in appearance.

#### URETHRITIS.

*Case 1.*—May 4, 1892, A. M., age 30; contracted disease in December, 1891. For ten months thought himself well. Discharge recommenced May 1, 1892; slight, free and painless; no treatment.

May 1. Treatment: Intra-urethral (from neck of bladder to entire mucous surface), 2 to 3 milliampères electric.

May 11. Electric diffusion from copper electrode, 2 to 3 milliampères. A brass bulb of proper size and connected to an insulated stem was passed as far as the neck of the bladder, the current turned on and the electrode then slowly withdrawn, thus bringing under the influence of the cupric and zinc diffusion the entire urethral surface. The dispersing electrode was placed upon the abdomen.

May 13. Patient reports that the discharge has entirely ceased. Later on he reported that it never returned and he remained cured.

*Case 2.*—A. M., March 19, 1893. One year later the patient referred to in Case 1, exposed himself to a new infection and contracted a severe attack of urethritis. Mindful of his previous cure he returned for the same treatment. The discharge was profuse, whitish and of the usual consistency; there was pain upon micturition. Treatment: Electric diffusion from copper, 4 milliampères, the electrode slowly withdrawn. At one moment when the electrode temporarily adhered or "stuck," the current was reversed to negative to loosen it.

March 27. Reports that he is much better.

March 29. Reports to-day complete cessation of the discharge after the treatment of the 19th, but that he has now a slight relapse from "drinking too much." Treatment renewed.

March 31. Reports that he is cured.

It may be noted here that extreme care to prevent adhesion of the electrode to the mucous membrane must be exercised in these cases. A delicate milliampèremeter is imperatively necessary, as well as a good rheostat. From 2 to 3 milliampères of current is sufficient and the electrode must be kept in motion. At least this is the method of treating the urethra which has forced itself on my atten-

tion as essential. It is beyond question the great feature of this method, in contra-distinction to that by injections, that the mucous membrane is electrically permeated with any given metallic salt, say the chlorid of zinc or copper, rather than simply superficially washed by a solution of the same salt. There is an actual chemic union of the metallic salt and the deeper albuminous constituents of the tissue.

#### TUMORS, ETC.

*Case 1.*—May 18, 1892, L. S., age 60; vascular tumor on upper lip, nine years' standing, increasing in size. Three-fourths of an inch in diameter, bluish cast of color and can be partially emptied by pressure. Treatment: Electro-cocain, local anesthesia; first punctured by a platinum needle, positive pole, 15 milliampères for ten minutes. Upon withdrawing the needle, considerable hemorrhage ensued. It therefore occurred to me to insert an iron needle, positive pole, and secure the electric diffusion of the oxychlorid of iron—a styptic salt. This was done with 15 milliampères for five minutes. There was no hemorrhage upon the withdrawal of the needle and the tumor shrunk visibly in size.

May 20. Tumor more compact; electric diffusion from an electrode 25 milliampères, twenty minutes. To withdraw the electrode without tearing tissue, the current was reversed at 15 milliampères for five minutes; no hemorrhage; needle almost destroyed by the action of the current. Tumor contracted.

May 23. Tumor reduced one-third in size. This patient did not return.

*Case 2.*—Feb. 13, 1894, Mrs. R., age 30; lipoma, one and one-half inches long by one inch wide at base of neck. Patient was unwilling to take ether to have the growth removed and did not want to have a scar. Experimentally, since I knew of no previous fatty tumor removed by electricity, I consented to try and extirpate it. Operation: Electro-cocain, local anesthesia, 7 milliampères, 10 per cent. solution cocain for ten minutes. A puncture was made with a microscopic trocar and the small piece of tissue sent to Dr. H. T. Brooke of the Post-Graduate School, Pathologic Laboratory, for examination. He subsequently pronounced it to be a lipoma. A copper electrode, three-quarters of an inch in length and one-sixteenth in diameter was inserted into the puncture made by the trocar, the skin being protected by the insulation of the stem of the electrode. The electrode thus sunk into the center of the mass of the tumor was allowed to remain for twenty-three minutes, with a current strength ranging from 10 to 25 milliampères. The resistance to the current flow was great, owing to the fatty nature of the growth. At 25 milliampères the patient had violent palpitation of the heart and was upon the verge of syncope, owing to the presence of the electrode near the great nerve trunks. The wound being antiseptic no special dressing was applied.

February 28. Patient reports that the tumor has entirely disappeared.

May 12. Patient returned to New York from Chicago and presents herself for examination. No trace of the growth remains; a slight red spot rapidly disappearing marks the site of the puncture. Cured.

*Case 3.*—May 16, 1893. M. H. H., age 25; wen or dermoid cyst. Tumor began six years ago, about the size of a pea on the neck below and behind the ear. Two years ago it began to increase in size and to-day is about one inch and one-quarter in diameter. The patient decisively refuses to take an anesthesia, wishes to avoid the scar from an incision and asks to have the tumor removed by the aid of electricity. Tumor hard and movable. Treatment: Electro-cocain, local anesthesia to skin over tumor; puncture made, contents of sac mostly expressed and cavity injected with a saturated solution of iodid of potash—a non-soluble metallic electrode remaining within the sac with the solution; a current of 15 milliampères was allowed to flow for ten minutes, with the purpose of setting free the iodine and obtaining its effect in a nascent state upon the lining of the sac.

May 19. No soreness. Tumor soft and pliable but hardening.

May 22. Tumor about two-thirds of its former size.

May 23. Tumor again filled and the operation was a most obvious failure. I resolved to try another method, viz., electric diffusion from a soluble metal. This was done with 20 to 30 milliampères of current for about ten minutes.

May 31. Slight serous discharge of an orange yellow color. July 1. Patient not seen again until this date, when he returned to state that the discharge had quickly ceased and that the tumor had entirely disappeared, leaving no evidence of the operation. Seen May 1, nearly one year later, there has been no recurrence. Cured.

## SYCOSIS PARASITICA.

E. H., age 50. Disease began seven years ago. Patient stated that he had tried to pull out an ingrowing hair and it broke off. A papule formed here, and following this a diffuse redness began to spread itself in all directions from the site (the left side of the face just in front of the ear); at the same time papules formed, coalesced and spread outward. No pus was formed at first but after a short time the tips of pimples became white and pus was discharged. This was followed by an exudation of serum from the excoriated surface and shortly before it was operated upon discharged in twenty-four hours one ounce of serum. He has been everywhere and tried every treatment to no advantage until last October, the 21st, when he was operated upon at the New York Post-Graduate Hospital by Dr. R. Y. Morris who removed the skin and subjacent tissue over an area in front of the ear about five and one-half inches long and two inches wide. Skin grafts were then applied which did well till one day about a week later he was out in the cold and a portion of the ears froze and had to be removed, which left when healed a scar two inches long and one inch wide in the center of the wound. All went well and the part looked healthy till February last, when signs of the old trouble began to show themselves in the skin just outside of line of incision, and when he presented himself to me the characteristic papules had spread themselves over a surface of about three inches long by two wide; in places the tissue was covered with small blebs and had a boggy appearance, into which a needle could be thrust for a distance of one-quarter of an inch without producing pain or discomfort.

April 20, he began treatment, which consisted of electric diffusion from copper electrodes  $1\frac{1}{2}$  to 2 milliampères ten to twenty applications, lasting in all ten to fifteen minutes, until the green oxychlorid of copper gave a distinct coloration to skin and tissue, using the positive pole, with the negative in back of neck. This was repeated eight times, the last one about May 10. The aluminium needle was used twice and the negative pole with equally successful results.

May 14. He came with the skin over lesion showing a normal and healthy condition. Treatment ceased with the injunction to return if there is the slightest evidence of recurrence.

NOTE—The alternatives in this case were, I am informed by Dr. Morris, further incision or curetting, both of which were objectionable, because the cicatrix was already extremely tense and no further tissue could well be sacrificed. The effect of the electric diffusion method was remarkable. It left behind it almost no observable cicatricial tension, in this respect much unlike ordinary electrolysis, and unlike the effects from the knife or the curette.

I have employed electric diffusion from metals in a variety of cases not here enumerated. Its action upon hemorrhoids has been to cure them in the few cases in which I have tried it. I have used it in endometritis, cystic degeneration of the cervix uteri, in ulcerations of the rectum, in keloid growths, etc. I am at present treating lupus and epithelioma with thus far favorable results, and have even begun upon a case of sarcoma, but it is too early to make any report upon this later set of cases. Dr. Gautier has reported excellent results in a great variety of gynecologic procedures and conditions.

## CONCLUSIONS.

1. The salts of many metals may be electrically dissolved from metallic electrodes, and at the same time be caused to permeate human tissue to a considerable depth. In the case of copper, upon dead tissue, with a current strength equal to that employed in living tissue, this depth is visible as an apple green color, in a radius about the electrode of from one-fourth to one-half of an inch; it probably extends invisibly much further, shading off to a minimum.

2. The electrically formed and electrically diffused metallic salts are not destructive to tissue in the sense that ordinary electrolysis is; the effect is rather by the presence of a partially insoluble salt and by the effect of a newly formed organo-metallic salt, de-nutritive or absorbing upon diseased tissues.

3. It would seem to the writer that these electrically formed salts, in forming new albumin composed of the metal used as an electrode possess a selective affinity for diseased in preference to healthy tissue, or at least produce a more profound reaction upon the morbid tissue, causing a favorable alteration in the nutrition of the part.

4. Electric diffusion is greatly superior to topical applications, for the reason that the medicament is caused to penetrate the tissue acted upon.

5. This method opens up a new and interesting branch of electro-therapy.

(To be continued.)

## SELECTIONS.

**Antispasmin, a New Remedy for Pertussis.**—Frühwald, in the *Archiv für Kinderheilkunde*, describes antispasmin (Merck) as a substance in which a molecule of narcein with sodium is united with three of sodium salicylate. It is freely soluble in water. Air and light decompose it, hence it must be kept in blue glass, well stoppered. It is expensive. The following dosage is recommended in whooping cough:

Children under 6 months 3-5 gtt. of a 5 per cent. solution three or four times a day; children of six months 5-8 gtt. of a 5 per cent. solution three or four times a day; children of 1 year 8-10 gtt. of a 5 per cent. solution three or four times a day; children of 2 years 10-12 gtt. of a 5 per cent. solution three or four times a day; children of 3 years 15-20 gtt. of a 5 per cent. solution three or four times a day; children over 3 years 10-15 gtt. of a 10 per cent. solution three or four times a day.—*Centralblatt für innere Medicin*.

**The Fate of Micro-organisms in Various Articles of Clothing.**—

(A. D. Nikolski, *Wojennomedizinsky Journal*, September, 1894.) The writer tries to ascertain to what extent the physical properties of materials can be regarded as favorable to the extension of the life of micro-organisms. Experiments show that in coarse, rough and porous stuffs, micro-organisms retain their vitality longer than in more compact and smoother. The explanation is that the thick and porous stuffs can absorb more moisture and retain moisture longer than thin, smooth and compact textures. Further, materials which, after infection, are exposed to light, furnish a smaller number of colonies than those which are secluded from light, and vitality ceases more quickly. These experiments were made with staphylococcus aureus, the bacterium of typhus abdominalis and the cholera bacillus.—*Centralblatt für Chirurgie*.

**Review of Twenty Cholecystotomies.**—C. Erasmus classified

twenty cholecystotomies performed by him, as: 1, cases in which gall stones were found; 2, in which a stone was found in the ductus choledochus; 3, in which no gall stones were found. In seventeen cases the patient had suffered with a typical colic, in the others there existed a tumor, evidently of the gall bladder. A tumor was present in eleven cases in all. In one case a movable kidney caused doubt in connection with an enlarged gall bladder, but it was shown that the symptoms for which the operation was performed were produced by a stone in the ductus choledochus. In eleven cases, icterus preceded. In eight cases, enlargement of the liver was observed. In performing the operation an incision along the outer margin of the rectus abdominalis is preferred to the cross-incision along the edge of the ribs (on the right), because with the former the gall bladder can be more easily sewed to the peritoneum. He then dissects up part of the peritoneum, and draws it, funnel shaped, down to the gall bladder. Once the incision was made in the median line because complicating conditions seemed to exist. This was in the case of the movable kidney already mentioned. The operation was performed as often at one sitting as at two; the contents of the gall bladder, whether purulent or serous, seem to have caused the decision. In one case an ideal cholecystotomy was performed, yet two months later the gall bladder had to be opened again and drainage made, on account of unendurable pain. In all other cases, drainage was carried out from the outset. The secretion of gall, omitting one case where it persisted several months, continued ten days to nine weeks. In one case it was necessary to use a suture for fistula; this was successful. One patient left the hospital before the closure of the fistula and was not seen again. All the patients were again seen shortly before the publication of the work, and could bear witness to their complete recovery. In no case had a hernia resulted, and in none did death occur from the operation.

The earliest case occurred May 20, 1890, and one more operation the same year; the rest in 1891, 1892 and 1893.—*Centralblatt für Chirurgie*.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

NO. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MAY 4, 1895.

THE OFFICIAL PROGRAM.

The program of the forty-sixth annual meeting is now completed and was issued May 2 to the Committee of Arrangements, by whom most of the copy was furnished.

The prospect for excellent Section work was never better, and the Association has never had a meeting which gave plainer evidences of the high scientific standard it has lately attained.

Socially the attractions are many, and the hard work done by the Committee of Arrangements shows for itself in the excellence of the arrangements for the meeting. We naturally would expect that a committee officered by CHISOLM, OSLER and ROHÉ would do credit to the Monumental City and the ASSOCIATION, and a glance at the program shows that expectation to have been well founded. Gastronomically, those inclined to the pleasures of the table will reflect that the "canvas back" has its nest very near, if it is out of season; that the succulent Chesapeake oyster has never yet been accused of conveying germs of typhoid, while the terrapin, that treasure of the gourmet, may always be found at its best.

Baltimore itself, with its historic associations; the chivalry of its men; the beauty of its women; the great extent and variety of its educational institutions, and its art gallery, make it a city to which the annual pilgrimage will be made with much pleasure and profit.

The program is this year printed on the ASSOCIATION presses and the work was done by ASSOCIATION employes. As a specimen of the typographical art it is very handsome, and in every detail creditable to the JOURNAL office. Justice to the employes requires mention of the fact that the copy was not received until the 24th. The printing was finished May 1.

THE RUSH MONUMENT.

At the head of our columns this week appears the portrait of the foremost American physician, DOCTOR BENJAMIN RUSH. We can do little more than reiterate the sentiments of the powerful appeal made by the Committee on the Rush Monument, to the profession; to honor the memory of an American physician, at once a scholar, a patriot, a physician and a philanthropist. It needs no eulogy to set forth his virtues or the splendor of his magnificent deeds.

DR. BENJAMIN RUSH.

From a phototype from a painting by SULLY, in possession of the Pennsylvania Hospital at Philadelphia. Painted for the hospital shortly after his death in 1813.

The history of American medicine has done that. Let those now living put their hands in their pockets in the liberal spirit that should always actuate a member of this great ASSOCIATION, and end this talk at *this* meeting, by subscribing enough money to complete a monument that should have been completed long before the ASSOCIATION was founded.

Blank Applications for membership in the ASSOCIATION at the JOURNAL office.

# THE CONVULSIVE AND APOPLECTIFORM ATTACKS OF PARESIS.

The causes of the epileptiform and apoplectiform attacks of general paralysis or paretic dementia have not been adequately explained, and very few of the text-books enter into this phase of the pathology of the disease to any extent. The theory of SPITZKA that we have in the apoplectiform attacks an intense local congestion, amounting practically to a capillary hemorrhage, is a plausible one, but it only explains the mechanism, not the exciting cause. It is easy also to assume that in the more advanced cases the general inflammatory condition of the cortex of the convexity produces a state of irritability that can readily account for convulsive discharging lesions, but this, for its part, does not make clear the absolute though temporary local or general paralysis so often observed in this disease. Moreover these attacks, either convulsive or paralytic, are not so infrequently the very first manifestations of the disorder, which from the time of their appearance is plainly manifest, so that it would seem in some of these cases to have actually dated from the attack. Any prior symptoms, if they existed, were too insignificant to attract attention, and cases have occurred where friends or the patient could not recall any pre-existing aberrations from the normal condition, that could rationally be connected with the seizures or the succeeding paresis.

In a recent communication a prominent French alienist, M. LEGRAIN, endeavors to supply a probable hypothesis to account for the phenomena in question, by assuming a uro-toxemia of the blood, and claims that those paretics who are free from these attacks are those only who retain to the last the full functional activity of the kidneys. On these grounds he maintains that paretic dementia is not exclusively a disease of the brain and nervous system, but that its lesions are also to be sought in the viscera, and in the arterio-sclerosis which forms their common bond. He draws, moreover, a practical conclusion from these views, that free abstraction of blood by leeching is a useful therapeutic measure, relieving the system of the toxic products that are overwhelming the brain; and claims to have had practical demonstration of this fact.

While there is a certain degree of probability in M. LEGRAIN'S views, it can not be said that they are proved to be applicable in all cases of the convulsive or paralytic attacks of paretic dementia. There is, with the increasingly favored view of the syphilitic or at least the parasymphilitic nature of paresis, a strong suggestion of a specific toxin acting in these cases. When the attacks occur, as they do in some instances, after comparatively recent syphilis and the disorder falls under the head of what has been called syphilitic pseudo-paresis, there is no difficulty in the assumption of the action of such a toxin.

Syphilographers have long since recognized the possibility of the sudden overwhelming, in some cases, of the nervous system by the specific poison, and this is one of the ways it might very naturally demonstrate its presence. When, however, as in most cases of paretic dementia, the specific infection dates back some years and has since been quiescent, to say the least, with our present knowledge, the probability of a specific toxin may seem more remote, but the idea can not be absolutely discarded, until we know more positively the actual relations between syphilis and paresis. The directly acting cause of the attacks may easily be a vasomotor disturbance, but the origin of this is the question, and the action of some poison on the governing centers seems as probable a theory as any other,

The toxin theory, whether as proposed by M. LEGRAIN, or in other forms, has the advantage of being in accord with one of the leading lines of thought in pathology at the present time and seems, on the whole, to be as well supported by facts as any other. It has moreover, so far, the field to itself, as no other adequate one has been seriously advanced and supported.

## VARIOLA AND VACCINIA.

At the close of the Jennerian century the question of the relation between variola and vaccinia is still unsettled, and DR. AUSSET and M. BARRET have just furnished another interesting chapter to the controversy. In view of PASTEUR'S discoveries the majority of savants believe that immunity against variola, as it is against anthrax, is obtained by the modification of the virulent elements attenuated by cultures or by their passage through animal organisms. But since the development of the anthrax bacillus may be stopped by the presence of another microbe—the bacillus pyocyaneus—is there not some analogous action in vaccination against variola?

The experiments of the authors have been guided by these ideas. As far back as 1839, REITER had inoculated more than seventy cows with variola unsuccessfully; on the other hand, vaccinia thrived on these animals. In 1865 PROFESSOR CHAUVÉAU reported some very interesting facts to the Academy of Medicine which are known to all. CHAUVÉAU concluded that the two viruses are absolutely independent. In 1883 BERTHEL, of Lyons, repeated CHAUVÉAU'S experiments by the intra-venous method. At the same time WARLOMONT, of Brussels, made similar experiments and reached the same conclusions as BERTHEL. Neither by intra-venous nor by intra-cellular injections were they able to produce an eruption having the character of the variolic pustule or the vaccinic pustule. The works of ETERNOD, HACCUS and BOLLINGER have not modified CHAUVÉAU'S conclusions. Others, however, have reserved

their judgment on this question—among them NIE-MEYER, KUSSMAUL and STRUMPELL, DUPUY and JUHEL-RENOY. In their second chapter, MM. AUSSET and BARRET cite experiments tending to show the identity of vaccinia and of variola. In 1830 CEELEY and afterward THIELE obtained the transformation of variola into vaccinia. In 1882 VOIGT obtained in three cases the same results as the Lyonesse Commission, but he interpreted them differently and saw in the experimental eruption an abortive form of variola-vaccinia. VISCHER in 1886 argued that vaccinia is nothing but a modification of the variola virus. HIME, of Bradford, also believed this to be the case.

The experiments of the authors consisted of four series: 1, variolation and vaccination on separate heifers; 2, variolation and vaccination simultaneously on the same animals; 3, vaccination of the animals inoculated with variola and inoculation of the vaccinated animals with variola; 4, M. AUSSET, successfully vaccinated in 1890, was inoculated on both arms with lymph from variola—no result; and again, eighteen days after vaccination, with lymph from a heifer—no result. The experiments confirmed CHAUVEAU's ideas; one alone seems discordant: A woman of 33, in the hospital at Limoges for cardiac disease, was vaccinated with the other patients in April. A week after, she presented six characteristic swellings with the usual phenomena of vaccinia. On April 16 she felt a chill, followed on the second day after by vomiting, headache and fever. Finally, on the 21st, an eruption of variola appeared which ran its usual course. This was not general vaccinia—error, it was claimed, was not possible.

#### DEFENSE OF OPIUM EATING.

Having regard to the attitude of Great Britain in other matters affecting her commercial interests—quarantine, for example—the medical world, outside of the "right little, tight little island," will be inclined to look askance upon the conclusions of the Royal Commission, on the use of opium, just made public. We are told that the inquiry of the Commission was conducted on a wide scale and the decision was practically unanimous; that more than 720 witnesses were examined, including 152 called at the desire of the Anti-Opium Society; that every care was taken to obtain representative testimony, and that the Commission record their conviction that the evidence forms trustworthy ground for the conclusions reached.

And these conclusions are: "That the temperate use of opium in India should be viewed in the same light as the temperate use of alcohol in England. Opium is harmful, harmless, or even beneficial, according to the measure and discretion with which it is used."

Taken by itself, and with its qualifying phrases

"temperate use," "measure and discretion," this declaration might be regarded as harmless; it would mean much or little, more or less, to different individual judgments. Unfortunately, it does not stand alone; the drift of all the extracts of evidence published is in favor of the use of opium as a stimulant. "In the opinion of the great majority of native medical practitioners and representatives of large influential classes, this employment of the drug is attended by beneficial results. Opium eaters of fifteen to twenty years' standing appeared before the Commission. They believed the habit had done them good. Their appearance and vigor satisfied the Commissioners, at all events, that it had done them no perceptible harm. . . . The opium habit prevails among some of the most manly, hardworking, thrifty races of India. . . . Opium is consumed in the native army, and, the witnesses say, does no perceptible harm, and is often beneficial. . . . Opium does not appear to beget any specific disease. Opium eaters bear surgical operations as well as non-consumers, and the manager of a large insurance company said that after twenty years' experience, his company charged no extra premium on the lives of moderate opium eaters."

Exact figures as to the present value of the opium export from Bombay are not at hand; but it formerly amounted to some \$60,000,000 annually, of which about \$37,500,000 represented net profit to the government. Of late years there has been a relative if not absolute decline in the amount exported. But this of course has had nothing to do with this defense of opium for "moderate habitual use," by a Royal Commission.

#### "A STANDARD POPULATION."

The Registrar-General of England, according to *Public Health* for March, has recently emphasized the necessity, or desirability rather, of a standardizing of the population of the several European countries. By this is meant that, for international uses, there shall be population with fixed age and sex distribution so that the birth rates and those of deaths and marriages may be calculated by such a standard or "norm." It is pointed out by him that as the sex and age distribution of the population varies markedly in different nations, and as the rates largely depend upon such distributions, the rates in one country can not safely be compared with the rates in another, without correction for these differences in the constitution of the several compared populations.

A high birth rate, for a time at least, increases the death rate, but in ten or fifteen years, if there is no considerable emigration of young persons, the death rate will diminish, inasmuch as there will then be a large proportion of persons between the ages of 5 and 25 years during which age periods the incidence of mortality is at its lowest. Again, a population that has

a large proportion of elderly persons will, other conditions being equal, have a higher death rate than a population having fewer aged people.

"PRIVATE COLLEGES."—The dislike to give credit to a rival publication, which is an idiosyncrasy of some editors, occasionally causes a comical evasion. Thus, an English contemporary, using the JOURNAL's elaborate statistics of Medical Colleges and Medical College Attendance in the United States<sup>1</sup>, has the following item: "In 1892 there were 15,339 medical students in 98 public colleges in the United States, and nearly 18,000 in the 117 public and private colleges. In 1894 the number had risen to 17,701 in the public colleges and 21,186 in the public and private." The JOURNAL does not understand the distinction here made between "public" and "private" colleges. What the JOURNAL said—page 992, Dec. 29, 1894, was that, "Through the courtesy of the Deans and Registrars of 98 out of the 117 existing regular medical colleges in the United States and Canada," etc. The classification of these schools into "98 public colleges" and "19 private colleges" gives an air of originality to the item, to which the editor is entirely welcome.

## CORRESPONDENCE.

### Handwriting of the Insane.

PHILADELPHIA, Pa., April 18, 1895.

*To the Medical Profession:*—With a view to especially important scientific results, I am studying the handwriting of the insane; and request your aid by way of the loan of documents, letters or written memoranda, or information having bearing upon the subject.

My especial desire is to obtain a given form of letter from ten persons, suffering from different degrees of insanity, such as melancholia, hallucination, paresis, etc., any and all writing that will be of interest in the investigation.

In return for your kindness and help, I will forward to you, free of charge, a full and complete report, together with drawings, diagrams, etc., embracing a full description of my work, which will be of use, help and value to not only the medical fraternity, but to humanity in general.

Please note on each specimen of writing, the duration of the malady or disorder, together with any miscellaneous information which you feel will be of aid to the purpose in view.

All information sent will be held sacredly confidential.

Very respectfully yours,

RUFUS C. HARTRANFT.

### Fifty Years in one Place.

CLYDE, N. Y., April 30, 1895.

*To the Editor:*—As you seem to desire, for some purpose, the photographs of the members of the ASSOCIATION I send mine with the announcement that the past winter completes my fifty-first year in practice—fifty years of married life, and fifty years residence in the same house.

If any member of the ASSOCIATION can boast of as many semi-centennial anniversaries of a like character, I would like to see his name in print.

I also became a member of the ASSOCIATION at its meeting in New York City in 1864, the year of the election of its veteran founder, Dr. Davis, as President.

Yours truly,

D. COLVIN, M.D.

## SOCIETY NEWS.

**Ophthalmic Instruments.**—A table will be provided in the meeting room of the Section on Ophthalmology, for the purpose of exhibiting new instruments or preparations that have been invented or brought forward by members of the Section.  
H. V. WURDEMANN, Secretary.

**License to Practice in Pennsylvania.**—The State Board of Medical Examiners, representing the Medical Society of the State of Pennsylvania, will meet in Philadelphia, corner of Broad and Pine Streets, and in Pittsburg, Council Chambers, on Tuesday, June 18, 1895, at 2 P.M., to examine applicants for license to practice medicine in Pennsylvania. Blank applications and all necessary information can be obtained from the Secretary of Internal Affairs, Harrisburg, Pa.

H. G. McCORMICK, M.D., President of Board.

**Windham County (Conn.) Medical Society.**—Sixteen towns, representing the leading practitioners in each township, met in Windham, Tuesday, April 23, for the one hundred and second annual meeting of the Windham County Medical Society. The following officers were elected: President, F. A. Morrill, Putnam; Vice-President, F. E. Guild, Windham; Secretary, W. H. Judson, Wauregan; County Reporter, N. Hibbard, Danielsonville; Censors, Lowell Holbrook, Thompson, T. M. Hills, Willimantic; E. H. Davis, Plainfield, Fellows to Connecticut Medical Society meeting at Hartford, May 25: Chairman, C. J. Fox, Willimantic; J. Kent Putnam; S. B. Overlock, Pomfret; C. E. Hill, Killingly; L. Holbrook, Thompson; alternates, T. R. Parker, Willimantic; Omer LaRue, Putnam; J. H. Tanner, Brooklyn; W. A. Darling, Killingly; W. H. McIntosh, Thompson. Delegates to AMERICAN MEDICAL ASSOCIATION in 1896: T. M. Hills, Willimantic; E. A. Hill, Killingly; essayist, A. D. David, Willimantic; alternate, R. C. White, Willimantic. Delegates to various county medical associations in 1896: C. J. Fox, Hartford; J. B. Kent, New Haven; F. A. Morrill, New London; F. E. Guild, Litchfield; E. H. Davis, Tolland; W. H. Judson, Middlesex; T. R. Parker, Fairfield. The annual essay was read by Dr. W. H. Judson, on "Dosimetric Medication." It was a very interesting paper and called out general discussion. An obituary on the death of the late Dr. W. J. Lewis, of Moosup, was read by Dr. Davis, of Plainfield, and appropriate resolutions were passed. The following new members were elected: Dr. G. A. LeClarr, Danielsonville; Dr. W. J. McIntosh, Thompson; Dr. S. B. Oldershaw, Pomfret. Dr. J. A. Coogan, of Hartford, was present as delegate of the Hartford County Medical Society. It was voted to hold special meetings at Pomfret in June and at Danielsonville in September, and the next annual meeting at Putnam. The annual dinner, at the Hooker House, was an interesting feature of the meeting.

**An Appeal to the Medical Men of Illinois.**—The Executive Committee at a recent meeting decided to issue an appeal to the physicians of the State of Illinois, through their different medical societies and through individual members of the profession, urging upon them the necessity for prompt organization of the profession in the State. It is a fact that the State Medical Society of Illinois has fewer members than the State societies in other States, with perhaps two or three exceptions. This is due, no doubt, to the apathy of the profession in the matter of organization. The medical profession of this State can advance their interests in no surer way than by speedily forming themselves into compact societies, county, State and National, under the authority of the organizations already established; and the committee respectfully urge that every member of the regular profession in this State see to it that he is speedily enrolled as a member of the State Society. There are over seven thousand physicians in the State, and less than seven hundred members of our society. What wonder is it that a request of the

<sup>1</sup> JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Dec. 29, 1894; Jan. 12, 1895.

profession, as voiced through the State Society, receives so little attention at the hands of our Legislature? But let the Legislature once be apprised that the profession of our State are united, and that they request the passage of a certain measure in the interests of public health, of humanity, or of the profession, and it will be very speedily responsive to such request. Not only are these material interests best subserved by organization, but as well the science in which we are all working, which requires that those engaged in the same department of science shall frequently compare notes and transmit the result of their observations to their fellows through the regular channels of communication. Will you not, dear Doctor, aid in this great work of organization and become one in the active ranks of those who are enlisted in the cause of scientific advancement? The cost is but a trifle—the reward is great. *Send your name and formal application for membership to the Secretary of this Society, or to the Treasurer, as soon as possible.* It is not absolutely necessary that you shall attend the meeting. Your name, your influence, and your support, and such contributions as you may from time to time choose to publish in the Society Transactions, are necessary in order to give the medical profession of Illinois the same prominence, character and respect as is accorded to our profession in most of the other States in the Union. State pride as citizens, no less than professional pride as physicians, should induce all members of the regular profession to at once enroll themselves as members of the organized State Medical Society, and if need be to make some sacrifices to that end.

JOHN B. HAMILTON, Permanent Secretary.

**Association of Military Surgeons.**—The fifth annual meeting of this body will be held at Buffalo, N.Y., May 21 to 23, 1895. The general headquarters will be at the Iroquois Hotel, where provision will be made for registration. The Committee of Arrangements has provided for the entertainment of the members and their friends. On the evening of Tuesday, May 21st there will be a conversazione at headquarters; on Wednesday a reception; on Thursday a carriage drive to various points of interest in the city, a promenade concert and a review of the 65th Regiment N. G. N. Y. On Friday, leaving Buffalo at 9:30 A.M., there will be an excursion to Niagara Falls and probably on to Fort Niagara, to afford the members an opportunity of seeing the various points of interest at the great cataract, including the electric power plant, the battle grounds of Lundy's Lane, Queenstown Heights and other interesting places. Members are expected to be in undress uniform during the day and in fall dress, including side arms at evening entertainments. In connection with the meeting there will be an attractive exhibition of surgical instruments, dressings and appliances in which most of the leading houses of the United States will be represented. Addresses of welcome will be made by Hon. Edgar B. Jewett, Mayor of the city, Hon. Levi P. Morton, Governor and Commander-in-Chief of the National Guard of the State of New York, and by Dr. Roswell Park, President of the State Medical Society. Major Albert H. Briggs, N.Y. N.G., is Chairman of the Committee of Arrangements. The following papers have been promised for the meeting: The President's address, by George M. Sternberg, Surgeon-General, U. S. Army. Report on the Status of the National Guard, by Colonel Nelson H. Henry, Assistant Surgeon-General, N. Y. N.G. Experiments illustrating the degree of powder burn, as modified by the distance of the object, size and conformation of the bore, amount and standard of the powder and other practicable demonstrable causes, by Louis A. La Garde, Captain and Assistant Surgeon, U. S. Army. The location and removal of missiles from the cranial cavity, by George R. Fowler, Major and Surgeon, N. Y. N.G. On litters, by John Van R. Hoff, Major and Surgeon, U. S. Army and E. T. T. Marsh, Major and Surgeon, 71st Regiment, N. Y. N.G. Ambulance construction, by Dallas Bache, Colonel and Assistant Surgeon-General, U. S. Army and C. R. Greenleaf, Lieut.-Colonel and Deputy Surgeon-General, U. S. Army. Conservative surgery on the battle-field, by Colonel Nicholas Senn, Ill. N.G. The relation of concentrated food to active service demands, by Charles Smart, Major and Surgeon, U. S. Army. The location of sites for, and the construction of military posts in relation to proper sanitation, by Dallas Bache, Colonel and Assistant Surgeon-General,

U. S. Army. The relation of naval architecture to proper sanitation, by J. R. Tryon, Surgeon-General U. S. Navy. On the value of bromin in military surgery, by M. O. Terry, Surgeon-General, New York. The handling and care of wounded on shipboard, by A. C. H. Russell, E. R. Stitt and A. M. D. McCormick, Passed Assistant Surgeons, U. S. Navy. The post exchange from a medical standpoint, by Philip F. Harvey, Major and Surgeon, U. S. Army. Infected bullets, by Louis A. La Garde, Captain and Assistant Surgeon, U. S. Army. Fifty-two amputations of the thigh, by John D. McGill, Surgeon-General, New Jersey. Instruction of the Hospital Corps, by H. S. Turrill, Major and Surgeon, U. S. Army. The surgeons-general of the militia, by George Cook, ex-Surgeon-General, New Hampshire. Field hospital service, by Dallas Bache, Colonel and Assistant Surgeon-General, U. S. Army. Some experimental work with the new ball, J. D. Griffith, ex-Surgeon-General, Missouri. Gunshot wounds of the kidneys, by A. L. Wright, Lieut.-Colonel and Surgeon, Iowa N.G. On the travois litter, by Vladimir F. De Niedman, Major and Surgeon, Kan. N.G. Service of the National Guard of the State of New York during the Buffalo strikes of 1893, by Lewis Balch, Major and Surgeon N. Y. N.G. The National Guard of the State of New York during the recent Brooklyn strikes, by William E. Spencer, Major and Surgeon, N. Y. N.G. Service of the Illinois National Guard during the Chicago strike, by Charles Adams, Major and Surgeon, Ill. N.G. Method of caring for wounded on the field and in hospitals of Chinese and Japanese armies, by C. U. Gravatt, Surgeon U. S. Navy. Scorbatic manifestations in young subjects, by John C. Wise, Surgeon, U. S. Navy. Asepsis in military service, by Eduard Boeckmann, Assistant Surgeon-General Minn. N.G. A medical officer in the volunteer army, by F. W. Byers, Surgeon-General, Wisconsin. The Merriam pack, by Lewis Balch, Surgeon, N. Y. N.G. The prevention and suppression of dangerous contagious diseases in garrison and in the field, by H. Lincoln Chase, Assistant Surgeon, Mass. V. M. Heat and sunstroke at camps of instruction, by Orlando J. Brown, Mass. V. M. The mental evolution of the citizen soldier, by Charles W. Galloupe, Assistant Surgeon Battery A, Mass. V. M. A diagnosis tag for field use, by Wm. H. Forwood, Lieut.-Colonel and Deputy Surgeon-General U. S. Army. Some interesting papers also are expected from committees appointed at the meeting in Washington, D. C., last year.

**International Congress of Dermatology.**—The Third International Congress of Dermatology will be held in London, August 4 to 8, inclusive, 1896.

Officers: President, Jonathan Hutchinson. Vice-Presidents, (a) British: the President of the Royal College of Physicians; the President of the Royal College of Surgeons; the President of the Royal College of Physicians of Ireland; the Director-General of the Medical Department of the Navy; the Director-General of the Medical Department of the Army. Sir William H. Broadbent, Bart.; Sir Joseph Lister, Bart.; Sir James Paget, Bart.; Sir Richard Quain, Bart.; Sir Dyce Duckworth; Sir Douglas MacLagan; Sir Edward Sieveking; Mr. Alfred Cooper; Drs. G. F. Duffey, McCall Anderson, Hughlings Jackson, Allan Jamieson, Robert Liveing, Payne, Pye-Smith, Herman Weber, Wilks.

(b) Foreign: France, Dr. Besnier, Professor Fournier, Dr. Hallopeau, of Paris; Professor Leloir, of Lille.

Germany: Professor Köbner and Professor Lassar, of Berlin; Dr. Unna, of Hamburg; Professor Neisser, of Breslau; Dr. Viehl, of Cannstadt.

Austria: Professor Kaposi, Professor Neumann, Professor Lang, Professor Hans von Hebra, of Vienna; Professor Schwimmer, of Buda-Pesth; Professor Pick and Professor Janovsky, of Prague; Professor Jarisch, of Gratz.

Russia: Professor Petersen and Professor Tarnowski, of St. Petersburg; Professor Pospelow, of Moscow.

Italy: Professor de Amicis, of Naples; Professor Pellizari, of Florence; Professor Campana, of Rome.

Norway: Professor Boeck, of Christiania.

Denmark: Professor Haslund, of Copenhagen.

Professor Castello and Professor Olavide, of Madrid.

Balkan States: Professor Kalindero, of Bucharest.

Turkey: Zambaco Pacha.

Greece: Professor Joannu, of Athens.

United States: Dr. L. A. Duhring, of Philadelphia, Pa.; Dr. White, of Boston; Dr. J. Nevins Hyde, of Chicago; Dr. L. D. Bulkley, Dr. E. L. Keyes and Dr. Fox, of New York.

Canada: Dr. F. Shepherd, of Montreal; Dr. Graham, of Toronto.

Treasurer, Mr. Malcolm Morris. Executive Council: Chairman, Mr. Hutchison; Vice-Chairman, Dr. Colcott Fox.

Members: Drs. McCall Anderson, Brooke, Fitzgibbon, A. J. Harrison, Allan Jamieson, Payne, Perry, Sangster, Pye-Smith, Simon, Walter G. Smith, Stowers, Thin. Messrs. William Anderson, Alfred Cooper, Ernest Lane, Sheild, Shillito, Waren Tay. Ex-officio members: chairmen of committees, the Treasurer, the Secretary-General.

Committees: (a) Reception, Chairman, Dr. Radcliffe Crocker. Members, Drs. Brooke, Colcott Fox, Keser, Bowles. Mr. Lane, Mr. Sheild.

(b) Museum and Demonstration, Chairman, Dr. Stephen Mackenzie. Members, Dr. Abraham, Messrs. William Anderson, Hutchinson, Jr.; Drs. Perry, Stowers; Mr. Tay.

(c) Bacteriological, Chairman, Dr. Sims Woodhead. Members, Drs. Delépine, Galloway, Manson, Ruffer, Thin; Mr. Andrew Pringle.

Ex-officio members of all committees: the President, the Treasurer, the Secretary-General.

Secretary to Section for Syphilis, Mr. Ernest Lane.

Foreign Secretaries:

France, Dr. Feulard, of Paris.

Germany, Dr. Rosenthal, of Berlin; Dr. Taenzer, of Bremen.

Austria, Dr. Riehl, of Vienna.

Belgium, Dr. Dubois Havenith, of Brussels.

Denmark, Dr. Nielssen, of Copenhagen.

Hungary, Dr. Török, of Buda-Pesth.

Portugal, Dr. Zeferino, Falcão of Lisbon.

Holland, Dr. Van Haren Nomann, of Amsterdam.

Sweden, Dr. Welandar, of Stockholm.

Switzerland, Dr. Müller, of Zurich.

Italy, Professor Tommasoli, of Modena.

Spain, Dr. Padro, of Madrid.

Roumania, Dr. Petrini de Galatz, of Bucharest.

Argentina, Dr. Baldomero Sommer, of Buenos Ayres.

Australia, Dr. Finch Noyes, of Melbourne.

Egypt, Dr. Sandwich, of Cairo.

United States, Dr. George T. Jackson, of New York.

Brazil, Dr. Silva Araujo, of Rio de Janeiro.

Chili, Dr. Valdés Morel, of Santiago.

China, Dr. Neil Macleod, of Shanghai.

West Indies, —

Secretary-General, Dr. J. J. Pringle, 23 Lower Seymour Street, London, W.

#### REGULATIONS.

1. All duly qualified medical men, British or foreign, or others interested in science, invited by the Council, who shall have paid the fee of £1 sterling,<sup>1</sup> and who shall have enrolled themselves, shall be members of the Congress and entitled to the Volume of Transactions.

2. The official languages of the Congress shall be English, French and German, but with the permission of the President, members may express themselves in the language with which they are most familiar.

3. The proceedings of the Congress shall be embodied in a Volume of Transactions, edited by the Executive Council.

4. Communications relative to membership, papers, or other matters connected with the Congress, should be addressed to the Secretary-General, Dr. J. J. Pringle, 23 Lower Seymour Street, London, W., or to one of the Foreign Secretaries.

5. The fee for membership shall be payable in London, at or before the opening of the Congress.

It will greatly facilitate the work of the Executive if the fee is forwarded as soon as possible after May 1, 1896.

6. Members who are unable to attend the Congress shall receive the Volume of Transactions.

7. The subjects treated shall be of two orders: 1, those selected beforehand by the Executive Council and introduced by gentlemen chosen for that purpose by the Council; 2, those selected by individual members themselves.

8. Subjects selected for debate by the Council shall take precedence over those selected by the members.

9. The sittings of the Congress shall take place from 11 to 1 in the forenoon, and from 3 to 5 in the afternoon, of each day.

10. There shall be clinical demonstrations of patients every morning from 9 to 10:30, and every afternoon from 2 to 3.

11. Members contributing papers must submit an abstract of them to the Secretary-General on or before May 1, 1896, which will be printed either in full or in part, and embodied in the general program of the Congress which will be distributed at its opening.

12. At every debate, precedence will be given to gentle-

men who have communicated beforehand their intention to take part in it.

13. No papers lasting more than twenty minutes will be permitted. Speeches will be strictly limited to ten minutes each. MSS. of the papers read must be left with the Secretary-General before the end of the sitting. The Executive Council shall decide as to the entire or partial publication of such papers in the Transactions of the Congress.

J. J. PRINGLE, Secretary-General.

**Chicago Ophthalmological and Otological Society.**—Regular meeting held at Saratoga Hotel, March 12, 1895, Dr. Hotz in chair. There were sixteen members and visitors in attendance.

The minutes of the last meeting were read and approved.

Dr. GAMBLE showed a case of voluntary nystagmus. Patient was a man, 24 years old, always well. No eye trouble in family. Could voluntarily cause a marked lateral nystagmus by looking at an object about ten feet away. The movements are more rapid than in most cases of involuntary nystagmus. The movements last only about a minute and then another effort is necessary to call them forth. V. in each eye = 20-20; no asthenopia; never had headaches; fundi normal. The nystagmus is never involuntary.

Dr. COLEMAN showed a negro porter about 28 years old, first seen some months ago, with marked secondary syphilis and with papillomata on corneal limbus. All symptoms disappeared under mixed treatment, but patient left before cured. Now returns with another outbreak and papillomata on limbus and on upper lid. They are sharply defined, about 1 millimeter in diameter. Much photophobia and lachrymation.

Dr. DODD reported a case of corectopia and notching of both lenses. Mrs. S., age 35 years. Right pupil is displaced upward and inward; left is normal in position and reaction; both irides tremulous; both lenses displaced downward and backward and irregularly notched in upper part, this being due to lack of zonule at these points. Vision each eye = fingers at three feet; right with — 16. D = 20-200; left not improved with glasses because of choroidal atrophy. She has a brother with double corectopia.

Dr. HOTZ had seen a case where both lenses were dislocated upward and the lower border of each was notched.

Dr. PINCKARD had a case where both lenses were dislocated down and in, and the upper border of each had a smooth notch about 1 millimeter deep.

Dr. HOLMES had seen a case with Dr. Kipp, of Newark, where there was a notch both above and below.

Dr. CASEY WOOD read a paper on "Septic Embolism of the Retinal Arteries," and reported two cases. The first was puerperal, both eyes were lost by panophthalmitis but the patient did not die. In the second case only one eye was lost. As a rule where the general sepsis is marked, the trouble in the eye precedes death only a short time.

Dr. HOTZ thinks such cases must be rare because during service in a general hospital, he had seen a great deal of pyemia but never a case of septic embolism in the eye, except one case from puerperal cause.

Dr. COLEMAN had had two cases in both of which death had occurred shortly after panophthalmitis set in.

Dr. WESTCOTT had two cases in which death occurred and one where the eye trouble started while the patient was convalescing from pneumonia. The eye was enucleated and patient recovered.

Dr. COLBURN had a girl, 17 years old who in December, 1894 had tonsillitis with ulceration. During this time she became blind. First seen three weeks later. Marked neuroretinitis with hemorrhage which has slowly cleared and now V = 20-60. Dr. Colburn also showed a water color of an unusual form of albuminuric retinitis. He reported a case of girl injured two years ago; Now, O. S. V =  $\frac{1}{2}$ ; field about one-fourth size of normal; loss of sense of smell and taste; hearing about one-ninth; monocular diplopia. O. D. V = 20-20; field is normal. There is anesthesia of right arm and left leg.

Dr. COLEMAN thought there might be some organic lesion. Dr. GRADLE thought it was a typical case of hysterical amblyopia as described by Charcot. Prognosis is bad.

Dr. WOOD also thought it was hysteria and prognosis is bad.

Dr. HOTZ thought a normal fundus after two years was against an organic lesion.

Dr. WILLIAMS referred to a recent case in *New York Med-*

<sup>1</sup> The equivalent of £1 sterling is: French, 25 francs; German, 20 marks; Italian, 25 lire; American, 5 dollars.

*ical Record.* Boy, 11 years, had neuro-retinitis and at the time his color sense was much disturbed. After neuro-retinitis disappeared color sense became normal. Dr. Williams thought this suggested that the retina was the seat of change in abnormal color vision.

Dr. Hotz had a strong man, 28 years old, who on August 27, about 10 A.M. found right eye suddenly blind. About ten minutes later, could see light. Dr. Hotz examined him about 12 o'clock. Lower field gone and upper field contracted. Retina was hazy above macula, the haze having a sharp edge. Superior artery was large to first branch, from there on was empty. Next day marked edema of retina above and vessels very small. Third day, a hemorrhage in upper nasal part. Massage was employed every day. Patient disappeared but came under Dr. Wood's care some days later. Massage continued and an iridectomy done. Field increased in size and central vision = 20-20. Vessels continued thread-like.

Dr. PINCKARD had seen a case of embolism of the superior artery where the embolus did not entirely occlude the vessel and the blood moved slowly along in a broken column. On the third day the arterial circulation was completely restored. At no time was the blood column in the veins broken. There was marked edema of retina but no hemorrhages. The patient recovered entirely without treatment. On motion, Society adjourned.

C. P. PINCKARD, Secretary.

103 State Street.

## NECROLOGY.

JOHN P. WALL, M.D.—The Editor has received from a mutual friend, the following statement of the sudden death of the late Dr. John P. Wall, of Tampa, Fla., long a member of our Association, and a gentleman of high standing in his community and State. The record of his service during the Tampa yellow fever epidemic, in which he served faithfully as one of Surgeon-General Hamilton's assistants, having immediate charge of affairs in Hillsborough County, is a bright chapter in sanitary annals. As will be seen, his death occurred while reading a paper on hygiene before the Florida State Medical Association:

"Perhaps the electric spark has already conveyed to you the sad intelligence of Dr. Wall's sudden death. If it has, then I am late in my announcement but not late, I know, in giving you some of the details of the unhappy ending of one of Florida's brightest and most illustrious physicians. He truly died in harness and was at labor in his chosen and loved profession up to the very moment when the summons came. The Florida Medical Association was in annual session at Gainesville and it was the third day of the session. Dr. Wall had been announced in the Section of Hygiene to read a paper on "Public Health in the Light of Recent Observations and Experiments," and 9:30 A.M., the 18th instant had been made the special hour and order for its delivery. The Doctor was a little late getting to the hall, having been to see some patients with Dr. Lancaster of Gainesville, but he arrived before the appointed hour. He appeared in his usual health that morning and in fact said to some friends that he never felt better. He began reading, standing, but appeared much agitated and very nervous, as was manifested by a restless moving of his right hand, he holding his article—which was in printed proof-sheet in his left hand. He was pale and his voice trembled, which I in common with other members ascribed to a timidity (stage fright) which the Doctor always manifested when addressing an audience. He had read but a few sentences when he sipped water and then seemed to recover his self-possession, but the agitation returned soon again with increased pallor and he again drank water, remarking *sotto voce* to those near him that "high teas" and "tony" entertainments did not agree with him (alluding to the reception of the night before) but he did not complain otherwise, then, of feeling badly. It was soon apparent (in fact I noticed it as soon as he began his paper, and remarked the fact to Dr. Daniel sitting in front of me) that there was something wrong with the Doctor, and Dr. Caldwell called to him to take a seat. He seemed to understand and reached for a chair near by him, but sitting on the arm of the chair and slipping off, he fell on the floor. He gasped several times, had a convulsive twitching of the corner of his mouth, and hands, and was dead. As he fell the pallor was changed

to venous congestion of face and neck and a very few minutes after death was pronounced, his ears and back of neck were very decidedly blue. I judge he had been reading about eight or ten minutes when he died. There was no post-mortem, as but an hour or two remained to perfect arrangements to take the body home in time for the train.

"The shock was a great one to us all, and I think it is the first occasion (the first that I know of) where a medical man in a medical convention and reading a medical paper drops dead and, as I said at the beginning of my letter, he truly died in harness. He never spoke after he stopped reading and made an effort to be seated." Yours truly,

JOSEPH Y. PORTER, M.D.

JOHN BLACKMER, M.D., of Springfield, Mass., died April 15, aged 67 years. He was born in Plymouth, and was graduated in medicine at Harvard University in 1854. In the late war he served as surgeon with the Forty-seventh Massachusetts Volunteers, whence he was transferred to a position as assistant surgeon in the U. S. Navy. After the war he became superintendent of the New Hampshire Asylum for the Insane. He was prominent in prohibition politics, both in the State last named, and later in Massachusetts.

ELON J. LAWTON, M.D., of Rome, N. Y., died April 18, in his sixtieth year. He was a graduate from the Albany Medical College, in the class of 1858. For the past four or five years he had been a member of the common council of the city named, and formerly for the period of twelve years ending in 1882 he had been the coroner of Oneida County.

JOSEPH L. WADE, M.D., of Irvington, N. J., died April 20, aged 66 years. He was graduated in medicine at the New York University, when he was 21 years of age, and soon thereafter established himself in practice in his native town. He had been health officer of the village for ten years, and was one of the best known citizens, having been born in the township at the outskirts of the old village, and lived there constantly except during the four years he served as a surgeon in the Thirteenth New Jersey Volunteers at the front. He was a steady contributor to the Newark papers, and at one time published a paper called the *Irvingtonian*. He leaves a widow.

JOSEPH ROWLAND, M.D., the oldest practicing physician in Delaware County, died at his home on Front Street, Media Pa., April 29, with pneumonia. He was in the eighty-first year of his age and had been in active practice in this county for fifty-five years. He was a graduate of the University of Pennsylvania of the class of 1840. His entire life was given up to practice, and he leaves considerable property. He was a man wonderfully preserved for his years and was seen almost daily riding on horseback, his usual mode of travel. Dr. Rowland was twice married, his first wife, who died about twelve years ago, being Jane R. Eaves. Six children from this marriage are living, all married and heads of families. They are Dr. Frank Rowland, Dr. Beecher Rowland, Mrs. Mary Kater, Mrs. Charles Myles, all of whom reside in California, and William E. Rowland of Media, and Mrs. Sarah Garrett, of Westtown. Four years ago Dr. Rowland married his second wife, Anna Howard, of Media, who survives him. He had a wide acquaintance and many family connections in the county, and was held in high esteem, both as a citizen and a physician.

ISAAC WAYNE HUGHES, M.D., died at his home in Philadelphia, April 26. He was the second son of Benjamin B. Hughes, and was born in 1831, near Norristown, Pa., where he received his early education. He had among his school-mates and intimate friends of early youth the late Generals W. S. Hancock and John F. Hartranft. He entered the medical school of the University of Pennsylvania in 1849, and was graduated in 1852. He began the practice of his profession at Sunbury, Pa., where he married Alice, daughter of the late Judge Charles Donnel, and, after a short residence there, in the year 1851, he settled in West Philadelphia, then a scattered village, locating at Fortieth and Chestnut Streets, where he continued to reside, actively engaged in

the practice of his profession, until prostrated by his fatal illness, which confined him to his bed since about March 1. Dr. Hughes was not only a successful practitioner of medicine endeared to his large clientage, not only for his skill and experience, and also by a pleasing personality of manner, but he was likewise an enterprising business man, and assisted in the improvement of that part of the city by the erection of a number of dwelling houses. He also organized the West Philadelphia Bank in 1869, of which he was the first and only President, and was also the President of a recently organized incinerating company. He had been for many years a member of the Philadelphia County Medical Society, and had been for a period of forty years a vestryman of St. Mary's Protestant Episcopal Church.

He numbered among his personal friends such distinguished men as the late Anthony J. Drexel, Chief Justice Ellis Lewis, Admiral Porter and Hon. Richard Vaux. He leaves a widow, a son, Dr. Donnel Hughes, and three minor children.

J. M. PRICE, M.D., of Brazil, Ind., April 19.—Edward Shippen, M.D., of Baltimore, Md., April 22.—Russell Caulkins, M.D., of Cleveland, Ohio, April 21.—Francis A. Slater, M.D., of Chicago, April 24, aged 78.—J. C. Humphreys, M.D., of Greensburg, Ind., aged 79 years.—William A. Lewis, M.D., of Moosup, Conn., April 20, aged 66 years.—J. G. Schnebly, M.D., of Topeka, Kan., April 24, aged 65.—Moses R. Greeley, M.D., of South Weymouth, Mass., April 23, aged 68.—R. M. Lackey, M.D., of Oak Park, Ill., April 29, aged 59.—Frederick Andros, M.D., of Minneapolis, April 28, aged 92 years.—Ezra Stetson, M.D., of Princeton, Ill., April 28, aged 78.—F. Thomas, M.D., of Racine, Wis., April 23, aged 29.

## PUBLIC HEALTH.

**Typhoid in the Milk Can.**—Secretary Lindsley of the Connecticut State Board of Health has run down the origin of a series of 164 cases of typhoid fever, all occurring among the patrons of one milkman in the town of Stamford, Conn. Inspection of a number of dairies from which this milkman obtained his supply revealed nothing suspicious, but the water of the well on his own premises—used for cleansing his cans and possibly for increasing the volume of his supply—was found to contain 69,660 bacteria to the cubic centimeter. Examination of a number of other wells in the vicinity also showed gross contamination and these have all been ordered to be filled up, and the milkman was at once forbidden to furnish any more milk.

**Vaccination by Scratching.**—Dr. H. Masson, a French military surgeon, up to last November had always used scarification as a means of inoculation with vaccine virus. He then abandoned it for a scratching method. The lancet, charged with the vaccine matter, is held almost perpendicularly to the arm between the thumb and the index, so as to use the point only. Then at the site chosen he scrapes the skin many times and very superficially, giving the instrument a slight to-and-fro movement from left to right and from above down. By this means only the epidermic cells are taken away. The vaccinal matter is spread out over this area and the garments are not replaced for eight to ten minutes. The results have been very satisfactory. Like M. Raffinesque, the author speaks of the enormous volume of the pustules and the severity of the inflammatory phenomena. With a view to reducing these, Masson limits the surface to be inoculated to about 2 millimeters square, thus obtaining pustules averaging 6 to 7 millimeters.<sup>1</sup>

**School Hygiene.**—On account of the small size of the plot of ground on which a public school in New York City is to be built, the architect has been told to build an out-doors playground on the roof. Following are some of the novel features

in the Henry Street school, which will occupy a space of 190 by 100 feet: the playground will be on the roof. It will contain 10,000 square feet of space, equal to four city lots. On the south, east and west sides, the playground will be protected by the roof, which will extend fifteen feet above the level of the playground. To the south, the view will be unobstructed, and protected only by a wire netting. It will be covered with a wire netting to prevent children from throwing missiles into the street. The playground on the roof will only increase the cost of the structure about \$4,000. As the total cost is to be about \$200,000, the additional outlay is a mere trifle, when the benefit to the pupils is taken into consideration. The first floor will contain an indoor playground. The floor will be of asphalt. The second, third and fourth stories are to be devoted to class-rooms, with sixteen on each floor. On the fifth floor will be the manual training school. Here there will be a gymnasium and cooking rooms, with kitchen and ranges, for girl pupils, who will be inducted into the mysteries of culinary art. The most unique feature will be the location, in the basement, of thirty shower baths for the free use of pupils. The bath suggestion has not been fully decided upon, but the plan has been submitted to the Board of Education, with indications that it will be adopted. It is possible that shower baths may not be built and that a big plunge bath may be substituted.

**Illinois State Board of Health.**—This body held its regular quarterly meeting in Chicago, April 30 and May 1 and 2. A number of questions concerning the recognition of medical colleges were discussed, but final action is not yet announced. The Secretary's report on contagious diseases shows that there were 105 smallpox centers outside of Illinois during the quarter and 26 points in the State with 90 cases and 15 deaths. The close of the epidemic in Chicago is dwelt upon, as already noted in the JOURNAL of April 13. A resolution was unanimously adopted by the Board, indorsing the administration of Dr. Arthur R. Reynolds, Commissioner of Health of Chicago, in which it is recited that he found "a practically unvaccinated community, requiring within the two years a total of 1,119,320 public vaccinations, more than one-half of which were performed within a single month; the hospital facilities were disgracefully and dangerously inadequate; there was no ambulance service, nor corps of trained assistants, nor appropriations to secure any of the essentials necessary to deal with an outbreak of a highly contagious and malignant disease." These difficulties were overcome and the outbreak was suppressed with a mortality of about 60 per cent. of the epidemic of 1871-74, of less than 45 per cent. of that of 1862-64, and of 26 per cent. of the great epidemic of 1880-83. The Board characterizes this wholesale immunization and its results as "an unparalleled achievement of sanitary administration"—"a triumph of preventive medicine which fitly closes the first century of Jenner's discovery."

**Eucalyptus-Oil Disinfection in Scarlet Fever.**—In a paper read before the Epidemiological Society March 15, ult., Dr. Joseph Priestley, the well-known medical Officer of Health of the much-quoted town of Leicester, Eng., details the results of his investigation of the use of eucalyptus oil as a disinfectant in scarlet fever—a method of treatment originally proposed and enthusiastically advocated by J. Brendon Curren of Teddington, and indorsed *pro tanto*, by publication in the Transactions of the Society. The treatment, as detailed, consists in the use of eucalyptus oil in a compound known as "oleusaban," which appears to be a proprietary article said to be composed of the essential oil of eucalyptus globulus with thymol and other camphors and aromatic disinfectants in solution. This is used by careful rubbings with the oil over the whole body three times a day for three days, followed by one rubbing after a warm bath daily for seven days. The disinfectant is sprayed also into the patient's throat, mouth and nose and diffused into the air of the room. No eucalyptus is administered internally beyond what passes down into the stomach during the spraying process. In brief, Dr. Priestley's results with 120 patients thus treated—as compared with 161 cases treated in the usual

## ADDRESSES.

### A FEW LIVING ISSUES AFFECTING THE HISTORY OF MEDICINE, AND WHAT CAME OF THEM.

The President's Address, delivered at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7, 8, 9 and 10, 1895.

BY DONALD MACLEAN, M.D., LL.D.

DETROIT, MICH.

The patriot poet of Scotland, Robert Burns, recalling the aspirations of his ardent young manhood, immortalized one of them in these simple but eloquent lines:

"A wish (I mind its power),  
A wish that to my latest hour  
Shall strongly heave my breast;  
That I for poor auld Scotland's  
sake  
Some usefu' plan or book could  
make,  
Or sing a song at least."

By simply substituting the larger term, Humanity, for the poetical and romantic one, Scotland, in this stanza, we have a sentiment appropriately expressive of the motive which brings us together to-day.

The annual meeting of the AMERICAN MEDICAL ASSOCIATION occurs at the brightest and sweetest season of the year and in most congenial surroundings. It never, as far as my recollection of its meetings extends, has failed to prove an occasion of delightful interchange of fraternal relations between its members, as well as a season of practical advantage to all sorts and conditions of men; influencing as it does, for the highest ends, innumerable interests and shedding rich blessings upon humanity, wherever sickness is to be healed, vice to be cured, life to be saved, or good to be accomplished. If the present occasion proves any exception to its predecessors, you will readily believe that my most earnest ambition is that this may consist in the fact that its endeavors shall be greater and its results more valuable than those of any previous meeting. So far as the surroundings and associations of our present place of meeting are concerned, we are indeed highly favored.

The members of an ASSOCIATION, interested in matters medical, philosophical, humanitarian, that could fail of being uplifted and inspired by the atmosphere and genius of this beautiful classical city of Baltimore, with its more than imperial halls of learning, its ideal and palatial hospitals, and beautiful charities, its world-famed scholars, philosophers and leaders of thought, must have reached a stage of indifference and lethargy painfully suggestive of that hopeless form of degeneracy known as "paretic dementia."

In the presence of this great and learned ASSOCIATION and in the midst of such impressive scenes of scientific and professional suggestiveness, it is with no little hesitancy and timidity that I invite you to accompany me in a brief and inevitably imperfect retrospect, having reference to what I have designated as "A few living issues affecting the history of medicine, and what came of them."

My purpose is to recall briefly, certain questions which in their day received the active and interested attention of the profession, and of scientific and thoughtful people. In doing this, I shall confine myself to the period of my own professional cognizance, namely, the forty years last past or thereabouts.

For some years immediately preceding and immediately following the beginning of my professional life, the attention of science and of medical thought was directed toward that renowned center of medical and general learning, my own alma mater, Edinburgh. A glance at the names which at that time constituted its medical faculty will explain this. They were Syme, Simpson, John Hughes Bennett, John Goodsir, Robert Christison, Lyon Playfair, Mr., now Sir William Turner, who is the only one still remaining of that brilliant galaxy of teachers and philosophers. Playfair still survives, but many years ago he abandoned academic pursuits and devoted his life and great abilities to statesmanship, being now a member of the House of Lords, a distinction rarely attained by a member of the medical profession.

Such a faculty could not fail to attract interested attention. While it is well known that at Edinburgh a vast amount of extremely valuable work was, in these days, accomplished in all departments of medical science, still there was, in that far-famed school, one man and one question toward which, from every quarter of the civilized world, eager anticipations were directed. This man was James Young Simpson, and the question was, "The use of chloroform as an anesthetic." Having caught the essential idea of relieving pain by the inhalation of ethereal vapors, from this country, Simpson, with the energy and courage of his great nature, devoted all his eloquence, ingenuity and literary acumen to the development and final establishment of the new doctrine. How he succeeded we now know full well.

Simpson and his followers advocated the tremendous innovation of administering chloroform, not only in surgery, but to suffering woman in her time of sorest need. The proposition aroused a tempest of opposition from all sides, not excepting the pulpit. All the unreasoning conservatism, not only of Great Britain but of the civilized world, was concentrated and arrayed against Simpson and his allies in this movement. He was maligned by his professional brethren, discredited by the general public and anathematized by certain parties in the church. All experience was against him, all theory was adverse to the

proposed innovation in practice. The Bible even, that messenger of peace and goodwill, was hurled at his devoted head and he was advised to read the sixteenth verse of the third chapter of Genesis and ponder it in his heart:

"Unto the woman he said, I will greatly multiply thy sorrow and thy conception; in sorrow thou shalt bring forth children and thy desire shall be to thy husband and he shall rule over thee."

To all his antagonists Simpson presented a brave and undaunted front. To all their arguments he opposed counter arguments which eventually settled the dispute advantageously to humanity and creditably to him. Asked by a high dignitary of the National Church of England on what authority he presumed to contravene the original curse pronounced against the woman, he aptly replies by calling attention to the closing verses of the second chapter of Genesis, which he claimed to be the true and authentic record of the first instance of the use of anesthetics, by which a precedent was established for all similar emergencies:

"And the Lord caused a deep sleep to fall upon Adam and he slept, and he took one of his ribs and closed up the flesh instead thereof."

The propriety and wisdom of using chloroform in labor is happily not now regarded as a *questio vexata*, although my own belief is that it is not yet used as frequently or as generally as it ought to be. I heartily agree with those who administer it in the trying stages of every case of labor. Simpson contended for its judicious use in cases of *puerperal*, *infantile* and other convulsions. So far as my own observation and experience go in this class of cases, it stands to-day the most valuable and reliable means of immediate relief. On calm and deliberate reflection is it possible, I ask you, to over-estimate the courage, the determination and the fine scientific faith of him who, in the face of such tremendous odds, fought to a triumphant issue, this great battle for science and humanity. If the annals of medical history furnish an equally brilliant example of well earned and priceless victory, I am at a loss to know where it is to be found.

Before leaving this subject it seems no more than fair to prefer a claim for a considerable degree of honor for one of Simpson's patients who proved also to be a powerful ally. I allude to a certain illustrious lady who, reposing sublime confidence in her medical adviser, and influenced we doubt not, by the consideration that the weight of her example must forcibly affect the great question at issue, did not falter in her brave determination (although every conventional influence opposed, and the great ecclesiastical organization of which she was and is the temporal head, held up a warning finger to restrain and deter her) of becoming a party to so startling and revolutionary a proposition. Gently but firmly pushing aside these and other influences, she gave the whole world a lesson, in the exercise of a reasonable and well grounded confidence in "*her doctor*," by submitting herself to the new and as yet almost untried obstetrical expedient, thereby instantaneously determining once for all the happy and victorious solution of this great and burning scientific issue, upon the everlasting and invincible grounds of truth and righteousness. What reason and argument and strong contention well-nigh failed to accomplish, the brave action of a confiding and gentle woman made easy and certain. For this act of roy-

alty may we not in all sincerity exclaim, "God save the Queen!"

In the year 1859, while I was a second-year student in the Edinburgh Medical School, the controversy connected with the introduction of anesthetics had barely been concluded when the scenes shifted, and immediately the movement of another great act in the drama of scientific progress began. For the scenes and acts of this mighty drama are continuous and unceasing. In it there is neither interruption nor interlude; on it the curtain is never rung down. In this year, Darwin's work, entitled "*The Origin of Species*," appeared in London, and as we look back and contemplate the effect of this book we are forced to admit that it constituted a turning point in the history of science. It appears now as if by its means the spectators were permitted to behold a new and hitherto unimagined and unimaginable view of the long sought for secrets of nature, making many things intelligible which, previous to that time, had been wrapped and hidden in that impenetrable and sepulchral vestment, "*mystery*." Like the wand of the magician it shed new light and inspired fresh hope along every highway and byway of scientific endeavor. Slowly but surely, men have come to see that Darwinism and the allied theory of evolution constitute the greatest and most radical living issue affecting the scientific thought of the last forty years. It is but a modest and feeble statement of the nature and extent of its claims, to affirm that the fundamental and far-reaching conceptions of Darwinism have forcibly and permanently affected every department of medical thought. By their influence, every department and every fact of the marvelous and beautiful drama of scientific evolution has acquired a new and greater significance.

It would be impossible, within the limits of this review, to particularize the luminous influences which have proceeded to every department of science, all of which had their origin in Darwin's great generalization. Foremost among these was one of profound biologic significance affecting all our previous conceptions of heredity. Heredity must always remain a prime factor in the etiology of disease. A correct conception of that in which it consists would appear to be indispensable for the comprehension of pathologic processes. Manifestly, if Darwin's law were true and if the acquirement of variations by means of natural selection was the cause of modification in the organism, not only must heredity be the cause of permanence in organic types, but it must also be upon transmission of beneficial variations that racial development is dependent.

These conclusions gave rise to a renewed application of the laws of heredity to medical science. Embryology became a matter of deepest significance. Teratology took rank as a science. Reversions in type began to be intelligible, strange growths were no longer viewed with wonder as *luses naturæ*, as sportive attempts of nature to accomplish something strange, but were studied carefully with an eye to their comparative classification. The Cohnheim theory of tumors arose, attributing to residual fetal cells a malign potency even greater than the doctrine of pangenesis would justify. The influence of Darwin on medicine can scarcely be exaggerated. Where is a better pathology of hernia to be found than in the "*Descent of Man*?" Notice how fertilizing an influence it brings to the study of obscure diseases. Dr.

Hector McKenzie, in his recent studies of Graves' disease, finds the cardinal symptoms of this disease, "tachycardia," "exophthalmos," "enlarged thyroid" and "muscular tremor" to be those of extreme terror. Darwin's explanation of the symptoms of terror is very suggestive. Men, during numberless ages, have endeavored to escape from their enemies or danger by headlong flight and violent struggling. Such exertion will have caused the heart to beat rapidly, the nostrils to dilate, the breathing to be hurried and all other symptoms of extreme physical effort, the final result being prostration, pallor and relaxation of muscles. "And now, whenever the emotion of fear is strongly felt, though it may not tend to any exertion, the same results tend to reappear through force of inheritance and association." If we imagine this condition of terror to become prolonged by failure of the nervous system to regain its balance, we then have a more or less complete picture of Graves' disease. Thus Graves' disease may be the expression, by the unconscious memory of the individual, of some shock in an ancestor. Nature has indeed a long memory. When she remembers her past so well, are we not arrogant in calling expressions of it "unconscious?"

While alluding to the influence of Darwin, especially through the doctrine of heredity, it would be wrong not to call attention to another sweeping generalization which must profoundly influence medical thought. The theory of heredity propounded by Professor Weissman, of Freiburg, may be said to have arisen out of Darwin's work largely through being a negation of some of Darwin's conjectures. Weissman's theory seeks to explain what no doctrine of heredity has hitherto accounted for,—how a single microscopic cell can reproduce parental characteristics, and frequently characteristics of grand-parents or remote ancestors. Darwin's doctrine of pangenesis was never felt to be entirely satisfactory. Weissman's theory of the "continuity of the germ plasm,"—the inference of the practical immortality of the germ plasm, the explanation of variation by means of natural not acquired selection, and the admission that a man resembles his parents, not because he acquires by transmission their characteristics, but because *he* as well as *they* arise out of the same germ plasm, these are conclusions which, if ultimately substantiated are bound to influence and modify our conception of disease and its processes most profoundly.

Those of us who can recall the birth and growth of this new philosophy, those of us who have been privileged to note the ever increasing influence of its teachings and methods on all our modes of thought, not only in the fields of abstract science, but in physiology, pathology and practice of medicine, not to mention other fields of effort, are fully persuaded that whether or not this may be set down as a live issue which has been finally and definitely estimated and disposed of, no more vital and far-reaching one has ever affected our views of natural processes or our methods of reasoning, whether as philosophers, scientists or practitioners of the healing art than this one so modestly and withal fearlessly set forth in the unpretentious volume entitled, "The Origin of Species," published in London in 1859.

Contemporaneously or nearly so, with the important issues referred to, we find another which, involving interests of the utmost importance was, from its nature not so capable of prompt demonstration, thus

furnishing cause of argument and disagreement for a number of years. I refer to the striking revolution in the theory and practice of medicine which resulted in the abandonment of blood letting and all concomitant so-called antiphlogistic expedients on which the profession has so confidently and comfortably anchored its faith from time immemorial. The change came gradually but certainly. It was useless to deny the fact of the therapeutic reformation, and it was a fundamental and beneficent one. The discussion and the disagreement was as to the why and wherefore of the change. One explanation ingeniously asserted was that the type of disease had changed and that as a result the treatment had to be modified and made milder and more merciful in order to conform to the new and more innocent character of the attack. Other explanations have been given, but it would be a waste of time to recall them. The fact remains that about the time that I and others equally inexperienced were inhaling our earliest draughts of scientific inspiration under the guidance of the great authorities already mentioned, these eminent men themselves were passing through a radical and complete change of belief and of practice. Whatever obscurity may pertain to the various steps and moving causes of this reformation we, from the vantage ground of our present position, are able to look back and with calm judicial fairness recognize the actual truth as to how it was brought about. It was no mere chance, no experimental haphazard change of fashion, no mere product of climatic or meteorologic influences; on the contrary, it was the rich and well earned reward of intelligent, earnest and persistent study and observation, carried on in the spirit created and bequeathed to the scientific world by John Hunter and others of his type. Among the notable names associated with this issue, not one, in my opinion, stands higher than that of John Hughes Bennett who, studying and intelligently interpreting the fundamental and essential phenomena of irritation and inflammation as seen by the microscope in the web of the frog's foot, the bat's wing, and other translucent tissues, had the genius and courage to turn his knowledge thus acquired to practical uses and discarding the ancient and accepted sheet anchors of antiphlogistic treatment, blood letting, calomel, antimony and so forth, determined to give the *vis medicatrix nature* a fair chance. Supplementing nature's efforts by mild and supporting methods he succeeded in reducing the mortality of pneumonia from 20 per cent. to less than 3 per cent. in the worst class of *complicated* cases, while in plain uncomplicated cases the mortality was reduced by Bennett from about 20 per cent. to *nil* or thereabouts. These statistics are presented on the authority of my friend Prof. John A. Ouchterlong, of Louisville, Ky., and can not be questioned. And what was even more important he persuaded the whole professional world to pause and reflect. By imitating his methods of observation and reasoning, the profession, in the true spirit of scientific modesty yielded more implicit honor to nature and to nature's powers and methods of healing. In the accomplishment of this impressive transformation scene in the drama of scientific medical progress, the leaders of thought on this side of the Atlantic, to their honor be it said, furnished prompt, intelligent and effective assistance. This is one of those living issues, one of those stirring and inspiring acts in the drama of scientific

progress, the happy accomplishment of which I and my cotemporaries have been privileged to observe and take some part in. In close and rapid succession we encounter other issues to be enumerated in this review.

In the humble office of a poor and unknown physician in Alabama, and almost simultaneously in a small and comparatively limited and insignificant ward of the royal infirmary of Edinburgh, initial arrangements were wisely made in all scientific modesty and earnestness for the ultimate presentation of a marvelously important and beautiful scene in the great drama of practical medical science. In other words, by J. Marion Sims on this side of the Atlantic, and Simpson on the other, with the support and assistance of their immediate allies and associates, the science and art now known as gynecology was conceived and rapidly matured. From very insignificant and unpromising beginnings this science has certainly, as we all know, increased and grown and, in short, passed through an almost miraculous process of evolution. Although some of its claims may be extravagant and some of its methods objectionable, and its condition as a whole capable of improvement and refinement, we are bound to claim for it a most exalted and honorable position among the living and successful issues which have contributed to render memorable that portion of the great history of medical progress with which we are now concerned. For the vast amount of blessing it has afforded to suffering woman let us give sincere and heartfelt thanks. For any failures or blemishes with which this modern child of noble origin may be tainted, let us cherish the hope that these will at no distant date disappear by a gradual process of elimination and evolution.

In this retrospective view of living issues in medical thought, it would be impossible to overlook the important and inspiring one comprehended under the name of "the cellular pathology." With this page in the history of our science, the great name of Virchow will always be inseparably associated, as its founder and greatest advocate. Based on this great teacher's amazing and fascinating discoveries and deductions, a kind and degree of sanguine expectation was induced in the minds of many people, eager and perhaps too willing to believe that here at last the keynote of all pathologic speculation had been struck, that the solution of all the mysteries of the origin and nature of tissue degenerations was within their grasp, that in the tersely expressed principle "*Omnis cellula e cellula*" was comprehended the master key by which all the hitherto tightly locked avenues of pathologic truth were to be made an open sesame. It may be possible to look back and perceive that this confident expectation, was to a great or less extent, misplaced and doomed to disappointment. It can not be denied that there are even yet, in spite of the cellular pathology and all that has come after it and through it, a good many very deep and dark mysteries still unsolved in the domain of pathology. And yet is there an individual here present, is there a member of our profession anywhere who is not willing to pay sincere and loyal homage to the cellular pathology for its own sake, as well as to its immortal founder and his school for all that it made possible in the advancement of pathology, as well as biology generally?

My old friend and classmate, Mr. Lawson Tait (to

whom, in common with my professional brethren everywhere, I am always ready to acknowledge a vast debt of gratitude for the eminent services which he has rendered to our profession and to humanity) has ventured to speak in terms of sarcasm and contempt of the cellular pathology. He tells us that when he entered the profession everybody was "mad after a new cell," and he adds, "a cellular pathology grew up which was to explain everything." The implication is obvious that everybody *did not* succeed in finding a new cell and that the cellular pathology *did not* explain everything, all of which is no doubt only too true. It is incomprehensible (to me at least) that Mr. Tait can believe or that he can expect other intelligent students and thinkers to believe that the cellular pathology of Virchow and his school does not stand out to-day as one of the most inspiring and beautiful features in the history of medical effort and thought in this age.

To say the very least, it constituted in its day a stepping stone of the most vital and critical necessity, without which the onward and upward march of pathologic and biologic progress must inevitably have been grievously delayed and embarrassed. Mr. Tait or any one else who presumes to sneer at or belittle this product of Virchow's genius writes himself down in my opinion on a plane with the illiterate and unesthetic bucolic immortalized by Wordsworth in the well known lines:

"A primrose by the river's brim  
A yellow primrose was to him  
And it was nothing more."

Pasteur, Tyndall, Lister; the mention of these three names, familiar wherever the rays of modern civilization have penetrated is, I am sure, all that is necessary for the purpose of introducing here the ever fresh and all important "living issue" known as the "germ theory of disease."

It would be little short of impertinence for me to inflict upon you any extended dissertation on this great issue, in regard to which such ample facilities have been furnished for enabling every individual to obtain the fullest knowledge from which to form an intelligent opinion as to the precise value of this theory to practical medicine and surgery. This, at all events, will be freely conceded, that from the time of Hippocrates down to the present moment, the history of medicine will be searched in vain for another instance of the application of scientific facts and observations to medical theory and practice secured by patient untiring effort that can for a moment be compared with this one. Starting with Pasteur's abstract, and so far as practical medicine and surgery are concerned, we might almost say, aimless experiments and observations, like a photographic negative, gradually but beautifully it has developed and grown, until the whole theory of the healing art has come to be thoroughly modified and colored by its influences.

It was undoubtedly the inspiration derived from the Darwinian doctrine of the struggle for existence, ultimately securing the survival of the fittest, that gave new significance to the studies which had begun with Pasteur, and whose relation to surgery had been so splendidly demonstrated by Lister in a series of brilliant and conclusive experiments in 1865. If life from its abstract standpoint were a conflict in which the fittest survived, how much more so was the concrete and organic life the scene of a perpetual warfare with those insidious foes, the microbes. It

is not possible here to trace the growth and development of the new science of bacteriology which we know has revolutionized the science of surgery, modified the art of surgery and subverted our deepest, most fundamental pathologic beliefs. So essential has this science become that to-day we regard no young practitioner as thoroughly equipped for surgical work who is not something of an expert bacteriologist. It is out of the study of bacteriology and microbic pathology that modern medicine is slowly but certainly evolving one of her supreme triumphs. Hitherto the immunity to attacks of smallpox conferred by vaccination has been an isolated and incomprehensible fact. Jenner's discovery has been a witness to the value of empiricism in medicine. In harmony with no theory, explained by no logical device, vaccination has by its own inherent virtue proved the value of *undiscovered theories*. To-day a meaning is given to the word "immunity" such as was never before known. A great hope animates the noblest of professions, that in all the so-called zymotic diseases, immunity may eventually be conferred and the most disastrous agencies of human destruction may be deprived of their malignity through the sublime genius of man.

It would be impossible to discuss at length the various theories of immunity, nor can I venture to attribute the degree of truth pertaining to each. To designate the particular rôle of the phagocyte in the competitive struggle graphically described by Metschnikoff—to decide whether the organism generates its own bactericides, or whether the so-called antitoxins and alexines are the product of certain suicidal tendencies on the part of the bacteria themselves—these are secrets which the laboratory is effectually disclosing. Some one has said, a man confronts his own worst enemy as he looks in his mirror, and it may be that the bacteria themselves are their own worst enemies. That while they are causing commotion within our bodies, they are really engaged in the work of self-destruction. However this may be, the recent experience of the profession in the antitoxin treatment of diphtheria, a treatment the introduction of which the Health Officer of New York already admits has lessened the death rate from that fell disease 40 per cent., indicates that after the lapse of many years vaccination for smallpox is not to stand as an isolated fact in medicine. Every fact has some relation to all other facts. "For a blade of grass to grow all nature must coöperate," says Diderot. If immunity can be given in one disease it certainly can in others. If there be one event that can accentuate this meeting in the memory of those who honor it with their presence it will, I firmly believe, be due to the fact that to-day we, as a profession, stand on the threshold of one of the most beneficent discoveries medicine has ever made. A discovery whose consequences will transcend those of any other in the increase of happiness it will ultimately bring to mankind.

In any attempt to review the living medical issues of the last forty years, it would doubtless be expected that reference should be made to the all-important one of medical education, a subject in which my own humble endeavors have been intimately involved. My first course of lectures in a medical college was given at Queen's University, Kingston, Ontario, in the session of 1864-65, and from that time to the present the question of medical education has been a

theme of vital thought and earnest ambition. In this country, in Great Britain, on the continent of Europe, everywhere, there seems to have arisen about that time a wonderful awakening to a new and better dispensation in the methods and principles of medical teachings.

The Edinburgh school led by Syme, Bennett and Gairdner, profiting by lessons derived from the great French teachers of that day, and from Mott and his contemporaries in this country, inaugurated a reform which soon spread in every direction. This reform consisted mainly in abandoning the ancient and time-honored method of aiming to impart efficient medical and surgical training by that dreary and painful device "the didactic lecture," supplemented by text-books whose orthodoxy and reliability were estimated chiefly by their antiquity and exhaustiveness. Gradually methods have become more practical, clinical, demonstrative. Place side by side a medical college announcement of 1865 and one of 1895 and the contrast will be astonishing and commendable for the profound and radical improvement sustained. The mighty impetus given to medical pursuits which resulted from the experiences incidental to our great Civil War culminated in the establishment of medical schools in unnecessary profusion in nearly every State. The immediate effect on the requirements for graduation of this feverish activity with its concomitant rivalry constitutes, we must admit, a rather unpleasant subject of reflection. Time and force of circumstances have gradually tended to adjust this error, and the standard of medical graduation in the majority of our schools to-day is something of which we may all be reasonably proud. I should, however, be untrue to my oft-reiterated convictions if I hesitated to mention here one cause of complaint still justly chargeable to a considerable number of our American medical colleges. It is summed up briefly but truthfully as follows: some of these institutions claim to supply to their alumni complete courses and means of instruction; the fact is that one-half of them are shamefully deficient in clinical resources and facilities, while the other half are no less devoid of the men and the means necessary to do anything approaching to justice in teaching fundamental branches, without which a reliable and intelligent knowledge of surgery and practice of medicine is an impossibility. It has long been a settled doctrine with many people that the highest duty, as well as the material interest of these unilateral medical colleges, demand that they mutually agree that the efficient half of each shall be made more and more efficient and that the feeble and farcical one be suppressed or transferred to that institution which may be best able to do justice to the subjects under dispute. Some such mutual combination is essential if in the continued maintenance of these two classes of medical schools they are to be purged of the sin and shame of false pretenses.

In the rapid evolution and growth noted in medical education, it has seemed to those most closely concerned that the time has arrived when a united and determined effort might be made to establish a well-defined plan which would secure uniform coöperation in remodeling the whole system of medical graduation, thus securing for the various designations of "doctor," "surgeon," "physician" and so forth an intelligible and definite signification. This, in my opinion is "a consummation devoutly to be wished."

I have thus far aimed to recall briefly a few living issues in medical thought which have had the most far-reaching influence upon the practice of medicine and surgery during my career as an humble student and worker in that great and honorable army, whose duty and glory consist in its efforts to save life and relieve pain. If my presentation of these "issues" seem to you incomplete and imperfect, I ask you to consider the vastness of the subject and the impossibility of doing it more than partial justice in the time at our disposal. On every hand, issues of the most tempting and impressive attractiveness press forward in one's thoughts and demand at least honorable mention, but the limit must of necessity be drawn with arbitrary decisiveness in accordance with the inevitable and relentless rapidity of movement of the shadow on the sun-dial. That the few topics which our limited time has permitted us to pass in review have been essentially fundamental in their relations to all the others will be freely admitted. That these are sufficiently important to give honor and distinction to the epoch in which they occurred no one will deny. And during this epoch is it not true that in every civilized country under Heaven, vast legions of men have been constantly maintained for very different aims and purposes than those which have engaged our attention? Think for a moment of the incalculable expenditure of energy of every kind which has been devoted to the maintenance and equipment of those vast standing armies whose business it is to

"March to the drum beat's roll.  
The loud-mouthed clarion's bray,  
And bear upon their crimson scroll,  
Our glory is to slay!"

Turning from the contemplation of these "marshalled hosts" and the death and destruction for which they are maintained, is it not a pleasant relief to direct our attention to such a peaceful and beneficent retrospect as that furnished by the labors and achievements of our profession? Is it not more pleasing to recall the quiet sublime efforts of our own contingent in the great "unending column" of life, that army which

"Moves in silence by the stream,  
With sad yet watchful eyes,  
Calm as the patient planets' gleam  
That walks the clouded skies.

"Along its front no sabers shine,  
No blood-red pennons wave;  
Its banner bears the single line:  
'Our duty is to save.'"

To sustain and improve this practical and genuine army of salvation, ought to be the living and moving ambition of every individual and every association. The United States Government maintains a standing army of at least 20,000 men thoroughly equipped and trained, for the purpose of destroying the lives of persons who are supposed to be inimical to its welfare. It leaves to us the responsible and laborious duty of maintaining and equipping, to the best of our ability, a vastly larger and more expensive army of medical soldiers whose functions are infinitely more numerous, intricate and vital than those of any military organization. The functions of this army are not only to contend with the enemies of human life and happiness and in so doing to suffer, oftentimes, hardships and privations, but unlike the great army of contention and bloodshed, it is also our duty and pleasure to love, cherish, uplift and save.

Ours is an army which so far has had to be self-sustaining and independent; an army which, in respect to all the attributes and qualities of the soldier and philanthropist has no reason to shrink from comparison with any association of men in the world's history. To many persons, myself among them, it has for some time appeared that the recorded and recognized results of our achievements give us the right to insist that the peaceful but brave, resolute and progressive army, known as the medical profession, should receive from the people and the government of this country a practical and official recognition which would afford a fair opportunity for the adequate application of the principles of medical science to the needs of the community.

A National Bureau of Health, superintended by a competent medical authority who shall be a member of the Cabinet, could not fail to secure for the nation, benefits beyond the language of dollars and cents to express. A united and dignified effort on the part of this ASSOCIATION and its allies ought to secure this enactment. The vast importance of such an act is obvious to the members of this ASSOCIATION, and our imperative duty, as it seems to me, is to impress the active and public-spirited statesmen, who guide and control the affairs of the nation, with the essential truth and value of our views. The very respectable problems of foreign policy which have, in recent times, engaged the attention and elicited the energies of our law-makers seem to sink into insignificance in comparison with the great and benign proposition here presented.

It is my deliberate opinion that the establishment of a Bureau of Health, as an integral part of the nation's executive, will prove an effective instrument in promoting the public welfare. It will be the means of unifying efforts in the suppression of dangerous diseases. It will afford opportunity for restraining the effete despotisms of the old world from adulterating our population with the vicious and degenerate. It will be a means whereby this enlightened and progressive republic may exemplify, to the world, the true mission of medical science. It will offer another agency for disseminating the truths of scientific discovery; another means of discriminating between that which is transitory and accidental in medical achievement and that which is permanent and immutable; and will furnish another promise that medicine in the future shall in no wise be unworthy of her past traditions.

The party, professional or political, which shall succeed in consummating this wise measure will assuredly earn for itself the gratitude and applause of an appreciative nation. The individual citizen who shall materially contribute to the success of this noble "useful plan" will be justified in congratulating himself on having realized the lofty aspiration of the patriot, as well as the sublime and pathetic "wish" of the poet: "*Homines deos accedunt hominibus dando salutem.*"

**Buttersack's Vaccine Micro-organism.**—Dräer (*Centralblatt für Bakteriologie und Parasitenkunde*) found the forms observed by Buttersack in lymph and claimed by him as the germs of vaccinia, in the contents of pustules after first as well as later inoculations, also in human serum, obtained by aspiration in pleurisy, in normal saliva and in albumin of hen's eggs. The last results prove that these forms can not be the specific cause of the inoculation pustule and that Buttersack's hypothesis is untrustworthy.—*Centralblatt für innere Medicin.*

## LECTURES.

## LECTURES ON INTRACRANIAL SURGERY.

## VIII—SURGICAL TREATMENT OF EPILEPSY.

BY EMORY LANPHEAR, M.D., PH.D.

ST. LOUIS, MO.

In every case of epilepsy where an initial spasm of a segment or a part of the body, or a localizing aura can be detected, trephining is imperatively indicated; for epilepsy is a disease incurable by other than surgical measures, as a rule, while many cases can be benefited by operation when the site of focal disease can be determined and reached. This proposition has met, and still meets, with opposition, the reasons urged against it being three in number, viz., 1, in some cases subjected to operation, the convulsions have returned within a few months after removal of the apparent cause; 2, in a number of cases reported the paroxysms continued after operation, undiminished in number and intensity; 3, sometimes epilepsy is cured by a simple exploratory operation, no lesion being discovered—hence the conclusion that whatever good results from surgical treatment arises from the operation *per se* and not from relief of brain irritation. A general distrust of operative procedure, too, has sprung up, based upon the unfortunate fact that there has been undue haste in operating upon patients that mature deliberation has shown to be affected with incurable forms of the disease; and also because enthusiastic surgeons, not too familiar with the history of epilepsy, have published premature reports showing “cures,” whereas the convulsive seizures returned almost before the articles were printed. Temporary cessation of spasms does not mean a cure of epilepsy, since it is a well-established rule—too little observed—to pronounce no case well until at least three years have elapsed after the appearance of the last attack.

But there have been too many well-authenticated and truly brilliant cures following surgical treatment of severe epilepsy due to depressed bone, tumor and abscess, to allow the unprejudiced physician to question the propriety of operating in any case of focal epilepsy. Nor is it necessary to have evidence of disorganization of the cortex; and I may add that under certain circumstances it is not even necessary to have marked localizing symptoms. For Péan reports the history of a patient who had suffered for years from inherited epilepsy, not traumatic; internal medication of every description failed; there was no localizing symptom except *pain*, which is not generally regarded as a sign of any significance in deciding the location of an intracranial disease; but in this case it was trusted and exploratory craniotomy performed at the seat of the localized headache and an angioma removed from the meninges implicating the superior longitudinal sinus; cure was complete and unquestioned.<sup>1</sup> Results like this in the work of operators of world-wide reputation certainly justify the hope that much may yet be done for many cases of epilepsy, even some not accompanied by the usual symptoms of the Jacksonian variety. In the present state of our knowledge, however, we are compelled to limit operative work to cases in which we can find some gross lesion to account for the trouble and those peculiar cases preceded by an aura.

<sup>1</sup> One of my cases of tumor, reported in a previous lecture, was an angioma of the meninges which caused such severe epilepsy as to produce imbecility.

Sometimes the disease appears to be due to a scar upon the scalp, or cranial fracture without depression yet attended by irritation of the peripheral filaments of the trigeminus; these are the cases which recover from simple removal of nerve implication by what is designed as a merely exploratory operation—liberation of nerves from adhesions relieving the irritation which gave rise to the nerve storms.

Epilepsy due to old depressed fractures is not as promising as Jacksonian epilepsy, judged by results thus far recorded, yet in view of Laurient's statistics of 102 cases operated on with 54 per cent. cured, trephining is surely to be advised in every suspicious case. At this point I can not refrain from calling attention to the words of Agnew upon the subject of depressed fractures in their relation to epilepsy; he says—and too much emphasis can not be laid upon it—that it is not too much to assume that poor surgery is responsible for the great majority of traumatic epilepsies, because of bad treatment at the time of injury, the old doctrine that depressed fractures of the skull without symptoms of compression require no operative treatment, being responsible for the many unfortunate sequels. I quote his own language: “However small may be the depression which follows a fracture of the cranium, save in one or two locations, it will encroach enough upon the dural nerves to cause more or less irritation—which, though insignificant at first, and perhaps not at all recognizable to the consciousness of the patient, yet if unrelieved will be transmitted finally to the cortex and brain ganglia until at last the paroxysmal explosion will occur. . . . Whenever, therefore, in my judgment, the medical profession can accept the doctrine that *all depressed fractures of the cranium, however slight may be the depression, and entirely irrespective of pressure symptoms, are proper subjects for trephining*, then will traumatic epilepsy largely disappear.” To-day, people will readily consent, even in the country, to operation at the time of accident if informed that a fracture of the skull is present, and as they become more familiar with the triumphs of aseptic surgery the mild objections now sometimes raised will disappear, and then indeed will the development of epilepsy due to depressed fracture be dependent upon the timidity or ignorance of the attending physician.

An injury to the frontal region, as well as to the motor zone, it must be remembered, is a very serious condition, and just as positively indicates operation; for 50 per cent. of non-trephined serious injuries to the frontal bone are said, by Garmany, to be followed by epilepsy, mostly succeeded by insanity. It may be truthfully added that 40 per cent. could be saved by prompt operative measures.

## INDICATIONS FOR OPERATING.

Upon general principles it may be asserted that the sooner operation is made after the development of the epilepsy, the better the prospects of success; yet the lapse of a long time—even years—is not a strong contra-indication, as numerous cases have been reported where removal of the irritation cured the convulsions even many years after the irritation began.

The special indications for trephining in epilepsy are one or more of the following:

1. An intense headache, always located in the same limited area, either preceding or succeeding the epileptic seizure.

2. Well-defined Jacksonian epilepsy; where the attack invariably begins in the same group of muscles and then involves the whole body.

3. The existence of a pronounced and constant aura that may act as a localizing guide; as a numbness in one extremity, etc.

4. Traumatic injury to the cerebral cortex; as depressed fracture, etc.

5. Semi-paresis or paralysis of any group of muscles not definitely shown to be of peripheral origin.

6. Direct evidence of removable lesion in or near the motor area; tumor, abscess, etc.

7. Hemi-epilepsy, even of unknown cause.

8. Even in cerebral atrophies of childhood, according to Starr, the frequency of the attacks may often be greatly diminished, though not cured—being due to organic changes.

#### PRELIMINARY TREATMENT.

Before resorting to operation (except in cases so plainly indicating surgical measures as to be beyond question) the patient should be subjected to the proper medicinal treatment; at the same time be put under careful observation of attendants thoroughly instructed as to the points to be noted; and repeated personal examinations be made to determine the exact seat of the source of the epileptogenic disturbance. Unless the history of the case is perfect as to the part of the body first involved in the attack, the determination of this is the first object to be noted; not at all infrequently the patient feels the spasm beginning in the hand or the foot, or has a sensation of numbness or tingling in some particular part before unconsciousness begins, but in others no such premonition exists, yet the spasm uniformly begins in a certain group of muscles and then gradually spreads until a general convulsion is on; as in one of my cases, the paroxysm consisted only of a convulsive movement beginning in the right hand, extending until the whole upper extremity and face were involved, with loss of consciousness, but no general convulsion. To carefully note these details is the object of the observation which may have to be continued for several weeks before the necessary data can be obtained. A study of the subject of cerebral localization must coincidentally be made if not *thoroughly* understood, or the services of a skillful neurologist engaged to assist in the case.

The medicinal treatment should consist of the administration of arsenic and the compound syrup of hypophosphites (National Formulary to be preferred), or other tonics which may be peculiarly indicated in any particular case. Bromids must be suspended for some weeks, so that the patient may be freed from their depressing effects. The patient is prepared for operation in the same manner as for any other trephining.

#### OPERATION.

After a large area of skull has been exposed over the proper region, search is made for external trouble and for fractures—as fissure of the skull so often occurs in apparently trivial injuries that there may be no history of an accident. Care must be exercised not to mistake a suture for the line of an old fracture as has sometimes been done. If any superficial source of irritation be found it is corrected in the special manner demanded by each individual case; excision of a scar in the scalp, liberation of nerves from adhesions, elevation of depressed fragments of bone, etc. Usually it is necessary to open the cranium.

If the skull be not too hard, the most speedy and satisfactory method of reaching the dura is by use of the gouge, but if it does not readily cut, the trephine is employed and a "button" removed somewhere near the affected region—*exact* location is not essential as the opening is to be freely enlarged; in fact, a large opening is generally preferable in nearly all cranial surgery, since simple relief from compression is almost invariably of benefit, even though no operation on the brain be made. Great care is taken in the use of the trephine in epileptic cases because the skull is likely to vary in thickness to a remarkable degree, even in the space of a half inch, as shown in this specimen mentioned in my last lecture as having been removed for the relief of epilepsy (case of osteoma). From this it will be seen how easily the trephine might injure the brain if applied near the end of the bony tumor.

Section of osteoma; actual thickness.

As soon as the dura is exposed the Keen's forceps are applied and the opening enlarged to at least one and a half by two inches. When sufficient bone is removed the dura is inspected. It may be that a depressed fracture has been relieved by removal of the bone—if so the impression in the dura shows it. There may have been a fragment of the inner table driven through the dura—if so, it is now visible. Osteophytes may have formed—if so, their presence is now discovered. Tumor of the meninges or cortex may be the cause of the convulsions—if so, the abnormal tenseness of the dura, or even its protrusion into the opening, is an indication for further exploration. The examination being completed, a large flap of the dura is now turned back, unless an extra-dural cause has been found and removed; and attention paid to intracranial abnormal conditions.

When it is evident that a depressed fracture has been corrected by removal of bone in the act of trephining, it may be taken for granted that the cause of epilepsy has been removed and no further procedure is permissible, unless some special reason exist for opening the dura—a step which adds greatly to the danger. So if the operator is satisfied, the scalp is closed with catgut drainage. But if spicula have been found projecting through the dura, the membranes are opened and fragments of bone extracted; it is not good practice to seize them and extract them by force, without first making a free opening in the dura; which is afterward sewed up.

Quite often osteophytes are found irritating the dura or the brain; in such case the dura is incised and the offending foreign bodies carefully extracted. Bleeding which oftentimes follows is quite copious and hard to control; a compress of gauze wrung from water at 105 to 110 degrees is applied with firm pressure for three or four minutes and usually is sufficient. In some instances it may be necessary to tie some vessel. If all other means fail, the tip of the Paquelin cautery may be applied, but it is objectionable and not to be recommended except as a *dernier ressort*; when used free drainage is always provided.

Tumors are excised in the manner described in the last lecture, the greatest care being taken to do as little damage as possible to the contiguous brain matter. Abscesses are evacuated, irrigated and drained.

Pachymeningitis, perhaps of many years ago, may be met with localized adhesions or effusion. If adhesions, they are gently broken up with much care not to injure the underlying brain; frequently, however, the cortex is very firmly attached to the membranes so that separation is impossible; when so, the particular part of the cortex involved is excised to the depth of a quarter of an inch by means of a very sharp knife or scissors. Iodoform is dusted in very freely after removal of the affected parts or separation of adhesions and the wound closed in such a manner as to secure primary union everywhere. If old meningitis with localized effusion be found, evacuation with irrigation, breaking up any adhesions present, and application of catgut drainage is all that can be done.

Sometimes—and this is occasionally true of very marked Jacksonian epilepsy—the most careful examination fails to show any focal lesion discernible by the eye or the finger; in such instances, Sachs asserts that excision of the affected area is the only rational treatment of the disease, and may prove wholly successful if long-continued irritation has not permanently injured other centers; and even if a complete cure is not effected, the frequency of the attacks may be diminished to the great comfort of the patient. The method is this: the motor area is stimulated by the application of electricity (an induced current from a Du Bois-Reymond coil furnished with one Daniell cell, or the Barrett chlorid of zinc battery) by means of two aseptic electrodes of platinum 2 millimeters apart. In handling these, the operator must envelop his hands in sterilized towels to prevent contamination; or better still they may be manipulated by an assistant who takes no other part in the operation, and who carefully protects the points from coming in contact with anything beside the brain after they are sterilized. As these electrodes are changed from one part of the motor area to another, careful observation will show response in each segment; when the particular spot is reached which causes motion in that part of the body first affected in the attack of epilepsy, the cortical and subcortical substance is excised. Bleeding is checked by gauze pressure or hot water—if not, the tip of the Paquelin cautery is applied sufficiently red to stop hemorrhage; the objections to the use of the cautery are that it requires drainage for some days, it causes a scar in the brain tissue much more marked than that following simple excision, and epilepsy may return as a result of excessive scar contraction. The wound is well covered with iodoform, closed with a few strands of catgut for drainage, and the usual dressings of sublimate gauze and cotton applied.

Following such an operation, paralysis of the extremity will occur; if a large area is cut away the paralysis will be permanent; if a small one, restoration of function may eventually be secured. There is considerable danger of death when a large amount of brain tissue is excised—much more than in removal of abnormal growths or deposits.

#### CASES.

In regard to Jacksonian epilepsy, one of my cases corroborates the assertion of Lucas Champonierre that the symptoms do not always coincide with the

location of the lesion. Briefly stated, the facts are these:

J. B., aged 13 years, when 5 years of age, fell and fractured his skull at the junction of the parietal and occipital bones. In spite of great depression of the fragment and long continued unconsciousness, the attending physician did nothing except to adopt the "expectant plan" of treatment. The child, however, made a rapid recovery from the accident and seemed in excellent health for some months. Then spasmodic movements were noticed from time to time in the hand and arm of the side opposite the head injury. These convulsive attacks increased in severity and extent until the whole side became involved and finally general epilepsy supervened. The epilepsy continued for years, the intellect finally becoming so impaired that the parents decided to consent to operation.

Upon reflecting the scalp I found a marked depression, which upon opening the skull was seen to affect the inner table much more than the outer, quite a fragment having been driven through the dura; this was found lying in a depression in the brain itself. After correcting this trouble, I extended the opening in the skull forward so as to permit examination of the Rolandic region. I could find no evidence of trouble here, so completed my work without further exploration. One severe general convulsion was noted on the third day, but though all antispasmodic remedies have been prohibited since there has been no further epileptic manifestation in a period of more than two years. I am therefore compelled to believe that the irritation was transmitted from the posterior parietal and upper occipital convolutions to the motor area.

Figure showing known areas in the brain and position of tumor—purely diagrammatic.

The local irritation in this case was in the angular gyrus, the supramarginal convolution and the first occipital. Whether there was "word-blindness" or not I could not determine, as the boy had never learned to read, though he has since done so. There was no hemiopia.

Upon the other hand, one may *exactly* locate the disturbing lesion and come within a fraction of an inch of its center in opening the skull. Thus in the case of tumor, reported in my lecture upon that subject:

P. P. B., of Norris, Mo., 28 years of age, presented the history of rapidly developing epilepsy, due to brain tumor. The only localizing symptoms were: epileptic seizures beginning in the thumb and index finger of the left hand, the muscles of the eyelid and the angle of the mouth—these followed by the typical symptoms of *grand mal*. Upon these "pointers" then a trephine was applied; the center pin of the trephine could not be removed and so penetrated the inner table; when the button of bone was removed, revealing a sarcoma of the dura, the center-pin was found to have pierced the exact middle of the tumor as shown in the specimen here exhibited!

How was such accuracy possible? Or was it mere chance? Here was a case presenting symptoms in different parts of the body anatomically quite remote from each other. Why should they indicate with any degree of precision the location of the tumor?

Examination of the diagram which shows the exact situation of the malignant growth, reveals the fact that the centers which preside over these widely separated sections of the body lie in contiguous fields of the motor region; and as our methods of external measurements are almost as exact as our knowledge of cerebral topography it was an easy matter to decide where to reach the causative agent in this particular epilepsy.

A number of other interesting cases of epilepsy have been operated on by me, two of which I mentioned in speaking of brain tumor, but none of the others, I believe, have passed three years since this treatment was instituted—so the time has not yet come for making positive deductions from my own work. Yet the results as thus far seen are satisfactory in all but one case—a most dismal failure—and encourage me in the belief that I have done right in operating in every instance; for the amount of benefit already given in the brief interval of three years or less is enough to repay for the time and trouble even though a return of the convulsions should yet occur. But I am satisfied a number of the cases will terminate in cure and I certainly shall continue to practice surgical treatment in every appropriate case, unless I meet with more evidences of failure than I have in the past.

In conclusion, I offer the following brief synopsis of our present ideas of what should constitute the

#### RULES FOR TREPHINING.

*When to Operate.*—1. An epileptic seizure invariably affecting a single group of muscles, or a general convulsion which always begins in a definite region may be regarded as sufficient guide to trephine over the area of the brain presiding over that particular part.

2. An intense *localized* headache preceding or succeeding each epileptic attack is sufficient to warrant exploratory trephining.

3. If a general epilepsy follow a depressed fracture the trephine should be advised—though results have not been, upon the whole, particularly brilliant.

4. In general convulsive epilepsy if paresis or paralysis of any group of muscles follows (even temporarily) an attack, trephining is admissible at the point indicated by cerebral localization.

5. Perversions of hearing preceding a convulsion (auditory auræ) point to trouble in the temporal lobe; exploratory trephining may have to be done upon both sides of the head.

6. Hallucinations of vision (visual auræ) strongly indicate lesion in the occipital convolutions.

7. An aura consisting of a disturbance of taste or smell justifies inspection of the temporo-sphenoidal lobes of both sides.

8. Aphasia (which may persist but for a moment or continue for several hours) sometimes is met as a symptom, and imperatively demands exposure of the left third frontal convolution.

*When not to Operate.*—1. No operation is justifiable in general epilepsy without some localizing sign and not dependent upon discoverable injury to bone.

2. Operation should not be performed in epilepsy which is clearly due to old pachymeningitis—the risks are too great in proportion to the good results to be anticipated.

3. Operation is not to be advised when there is a history of a previous lepto-meningitis (either traumatic, syphilitic or tubercular).

## ORIGINAL ARTICLES.

### CLINICAL NOTES ON PSORIASIS, WITH ESPECIAL REFERENCE TO ITS PROGNOSIS AND TREATMENT.

Read before the Medical Society of the State of New York, Feb. 7, 1895.

BY L. DUNCAN BULKLEY, A.M., M.D.

PHYSICIAN TO THE NEW YORK SKIN AND CANCER HOSPITAL, ETC.  
NEW YORK.

In his recent work upon the treatment of syphilis, Professor Fournier makes the remark; that too little attention is often paid to the real treatment and cure of the disease, and that too many physicians and patients are content with only the removal of the symptoms as they arise; it thus happens that in relatively few instances is the treatment of syphilis carried out in a patient and thorough manner to a cure. It is within the memory of quite young men when that disease was regarded as incurable, and it is only within the last decade that definite rules have been established (largely through the work of Fournier) which, if accurately carried out, will commonly result in the radical cure of syphilis.

Much the same may be said in regard to psoriasis; for, thus far, physicians and patients have been far too often satisfied with attempting to remove the eruption as it recurs, again and again, and commonly far too little study and attention has been given to the underlying cause and its removal. And yet I believe that the time has come when the treatment of psoriasis should be placed on a much more certain and definite basis than is now generally accepted, and the influence of diet and hygiene in its production recognized and when, consequently, we can offer to our patients much more encouragement as to a real cure of the trouble.

To the end of understanding better the clinical relations of psoriasis, and therefore its treatment and prognosis, I have made a study of my recorded notes of 366 cases in private practice, which have been under my personal observation and care. These cases occurred among 9,483 miscellaneous cases of skin disease, making it to form almost 4 per cent; it thus comes fourth on the list as to frequency, after eczema, acne and syphilis.

In a recent clinical study of 1,000 cases of psoriasis occurring among 25,443 cases of miscellaneous skin diseases in my public and private practice together, the proportion in public practice was found to be 3.69 per cent.

The ages of these 366 patients at the time of applying for treatment is shown in the following table:

TABLE I.—AGES OF 366 PATIENTS WITH PSORIASIS.

<sup>1</sup> Trans. Congr. Internat. de Dermat. etc., Paris, 1889, p 878; also Maryland Medical Journal September and October 1891.

It is here seen that males are affected with psoriasis more frequently than females, there being 212 males to 154 females, respectively 57.92 and 42.07 per cent.

The youngest patient seen with the disease was a male nearly 5 years of age, the oldest also a male just 75 years old. The largest number of patients applied for treatment between the ages of 25 and 30, when there were 63 patients or nearly 18 per cent of all the cases; but there were also almost as many cases during the five years of life before and after this period. Thus, together, during the fifteen years between 20 and 35 years of age there were 183 cases, or exactly one-half of the entire number.

It is impossible, however, to draw from this table any exact conclusion in regard to the age of the patient at which psoriasis is most likely to develop for the first time, for in many instances the disease had lasted for many years before coming under treatment, as will be seen in a later table. In the next table, II, is given the age at which the eruption first appeared, according to the statements recorded in the notes of the cases:

TABLE II.—AGES OF 366 PRIVATE PATIENTS WITH PSORIASIS, AT WHICH THE ERUPTION FIRST APPEARED.

	M	F	T
During infancy . . . . .	5	0	5
1 year to 2 years . . . . .	1	1	2
2 to 3 years . . . . .	2	2	4

60 to 65 years . . . . .	1	2	3
Not stated . . . . .	2	1	3
Total . . . . .	212	154	366

These cases are, perhaps too few to permit any very definite conclusions to be drawn from them, as to the first development of the disease, but a little study of the table develops many items of interest.

The disease belongs principally, to the early formative period of life. Thus, it is seen that in the largest number of instances, namely 76, or over 20 per cent. the eruption was first observed in the period between 15 and 20 years of age, and in a very large number, 63, between the ages of 10 and 15, while, the eruption first appeared in 197 cases, or almost 55 per cent. of the whole, between 10 and 25 years of age. After this period the number of cases diminishes very rapidly, there being only twelve patients in whom the eruption first appeared after 50 years of age. It is seen, however, that there are relatively few cases during very early life, there being only twenty-two instances in which it appeared before the age of 5 years. These facts appear quite opposed to the statement of Neumann<sup>2</sup> who asserts that the eruption generally appears about the sixth year of life.

It is a little curious to note that while the fe-

males are largely in excess between the ages of 10 and 15, in the next period of five years the number of males is nearly double that of the females; while, between 20 and 25 the males present nearly three times the number of cases found in females. The question arises whether the great difference relates in any way to the effect of the later development of the sexual function in males than in females.

Psoriasis is known to be one of the most rebellious of all skin diseases; beginning often quite early in life it may persist indefinitely, even in spite of active treatment, and often wears out the patience both of the physician and patient. In a certain small proportion of cases it will seem to disappear even without treatment, and to remain absent for varying periods, perhaps entirely. Such cases are, however, very rare, and the disappearance of the eruption seems to depend on some radical change in the mode of life, or sometimes follows a change of abode. A prolonged residence in a warm climate will occasionally arrest the disease, but it is liable to recur on return to a colder or more changeable climate. In some cases it becomes less pronounced after middle life and may become confined to a few lesions, giving little annoyance.

The duration of the eruption at the time of applying for treatment is shown in the next table, III:

TABLE III.—DURATION OF PSORIASIS IN 366 CASES AT THE TIME OF APPLYING FOR TREATMENT.

	M	F	T
Under 1 month . . . . .	7	8	12
1 to 3 months . . . . .	0	0	0
3 to 6 months . . . . .	7	5	12
6 months to 1 year . . . . .	20	15	35
1 to 2 years . . . . .	10	14	24
2 to 3 years . . . . .	9	8	17
3 to 4 years . . . . .	15	9	24
4 to 5 years . . . . .	12	9	21
5 to 10 years . . . . .	42	42	84
10 to 15 years . . . . .	25	22	47
15 to 20 years . . . . .	23	15	38
20 to 25 years . . . . .	19	3	22
25 to 30 years . . . . .	10	2	12
30 to 40 years . . . . .	8	2	10
40 to 50 years . . . . .	2	1	3
50 to 60 years . . . . .	0	1	1
Not stated . . . . .	3	1	4
Total . . . . .	212	154	366

This table fully bears out the chronic character of the disease, for there appear cases in it which had lasted thirty years or more at the time of first observation; in a very large number of instances eighty-four or nearly one-quarter of the entire number, the eruption had existed from five to ten years previous to the first visit.

The natural history of psoriasis is therefore to be reckoned by years rather than by days and months. Thus, of these 366 cases, no less than 221, or over 60 per cent. had lasted for five years or over.

Comparatively few cases were observed at or soon after the first appearance of the eruption, only twelve cases during the first three months, and only twenty-four cases in all during the first six months of the existence of the eruption. It will be seen later, that this is a fact of no little importance in connection with the proper treatment of the disease and its prognosis. Something more can be learned in regard to the obstinacy of the complaint by a consideration of the periods of time during which these patients were under observation. These are shown in the following table, IV:

<sup>2</sup> Neumann Lehrbuch der Hautkrankheiten, Wein, 1873, p 259.

TABLE IV.—DURATION OF OBSERVATION OF 366 PATIENTS WITH PSORIASIS.

	M	F	T
1 month or less (74 seen but once) . . . . .	95	45	140
1 to 3 months . . . . .	6	15	21
3 to 6 months . . . . .	14	16	30
6 months to 1 year . . . . .	32	28	60
1 to 2 years . . . . .	18	12	30
2 to 3 years . . . . .	7	8	15
3 to 4 years . . . . .	8	3	11
4 to 5 years . . . . .	5	4	9
5 to 10 years . . . . .	16	13	29
10 to 15 years . . . . .	6	7	13
15 to 20 years . . . . .	4	2	6
20 to 30 years . . . . .	1	1	2
Total . . . . .	212	154	366

Here it will be seen that a large number of the cases were seen but for a short time, 191, or over one-half, for a period less than six months, and of these, 74 were seen but once, and many others but two or three times. In looking over the notes of these cases, we find that some of them yielded to treatment and were apparently cured even in a short time, while many were lost sight of before any conclusions could be reached as to the value of treatment. In many of the cases which were for a longer time under observation, the notes show it was often for recurrences of the eruption, for these patients are commonly satisfied with its disappearance, and are seldom willing to undergo prolonged medical supervision with a view to the cure of the disease. In studying the records of these cases we find that in proportion to the length of time the disease has already continued, either before or while under observation, in about the same degree will the eruption resist treatment; in other words, as the disease becomes engrafted on the individual, the results are less satisfactory, much as is observed in connection with gout, with which, as we shall see, this eruption is frequently closely allied and, indeed, often closely connected.

This brings us to a brief consideration of the nature of psoriasis. Any one who has followed out cases of the disease during a period of years must be convinced that it is not a local affection, in the sense in which we speak of epithelioma, verruca, the parasitic eruptions, etc., and it is certain that it is not due to any specific poison introduced from without, as in the case of syphilis and leprosy, nor is there any definite evidence that it is of malarial origin.

Every evidence points to the fact that it must depend upon some internal cause, which at one time or another produces the changes in the skin. Unless, therefore, measures are taken looking toward the alteration or removal of the internal or general condition underlying the disease, we can not hope for a permanent cure. All have been disappointed again and again by the recurrence of the eruption, even after its complete disappearance under local treatment, and all acknowledge the futility of local measures to prevent its appearance or development.

What the exact underlying cause of psoriasis is, we are not yet prepared to say, but advances are being slowly made in this direction.

Heredity has been commonly supposed to have a very great influence in its production, and many writers state this with considerable positiveness. But as far as I can learn by a study of the cases here analyzed, as well as also from the much larger number seen in public practice, this element is of relatively little importance. Notes have been taken of all my private cases, and in most instances the pa-

tients have been carefully interrogated, both as to the positive and negative aspects of this question. The results are tabulated in the following table, v:

TABLE V.—HEREDITY OF PSORIASIS.

	M	F	T
Cases with anterior heredity . . . . .	28	16	44
Cases with posterior heredity . . . . .	6	6	12
Cases with no history of heredity . . . . .	131	111	242
Unknown or unrecorded . . . . .	47	21	68
Total . . . . .	212	154	366
ANTERIOR HEREDITY.			
Parents affected . . . . .	22	15	37
Grand-parents affected . . . . .	3	0	3
Parents and grand-parents affected . . . . .	3	1	4
Total . . . . .	28	16	44
POSTERIOR HEREDITY.			
Children affected . . . . .	6	6	12
Grand-children affected . . . . .	0	0	0
Total . . . . .	6	6	12
COLLATERAL HEREDITY.			
Cases with brothers affected . . . . .	23	13	36
Cases with sisters affected . . . . .	25	12	37
Cases with collateral relatives affected . . . . .	3	6	9
Total . . . . .	51	31	82

Here we see that of 366 cases only 56 showed any anterior or posterior heredity; in 68 cases there was no definite record, while in 242 cases, or over 66 per cent., there was no history of heredity, either in immediate ancestors or children, and in only 15 per cent was there any assurance that this had occurred. This certainly is not any greater proportion of concurrence than could be traced in many diseases, and bears no comparison with that found in eczema. In regard to collateral heredity we find 82 cases in which this was recognized, a no larger proportion than might be expected among brothers and sisters brought up under similar conditions as to diet, hygiene, etc.

As remarked before, it is often very difficult to determine with certainty the underlying causes which operate to produce the eruption, for it is observed in those presenting such widely diverse conditions of life, and under the greatest variety of circumstances. It develops with about equal frequency among the poor and the rich. Not only will it appear after exhaustive diseases, after pregnancy, and in those debilitated by various excesses, but it comes also in subjects who are apparently in the best of health and enjoying the surroundings of a healthy and apparently proper life. No single cause or element, or any combination of causes or elements can be traced in every case. The evidence increases, however, that it is more or less closely allied to the blood states which are known as the gouty and rheumatic; and we can often clinically identify the cases belonging to one or the other of these classes. Upon our recognition of the base upon which the disease rests will depend necessarily our success in treatment and consequently our prognosis.

Undoubtedly the most common systematic condition found is that associated with the still little understood suboxidation process, which underlies or is akin to that found in gout.

Sir Henry Holland<sup>3</sup> says: "I can not doubt from my own observations that certain of these (skin)

<sup>3</sup> Holland, Medical Notes and Reflexions, Philadelphia, 1857, p. 212.

disorders often occur as the result of the habit in question (gout). I have so often seen psoriasis, for example, occurring in gouty families—sometimes alternating with acute attacks of that disease, sometimes suspended by them, sometimes seeming to prevent them in persons thus disposed, that it is difficult not to assign the same morbid cause to these results."

Dr. Garrod<sup>4</sup> believes that psoriasis is, perhaps, the most frequent form in which the cutaneous (gouty) disease manifests itself, and that there are many cases in which the skin and joint affection are alternated.

Sir Thomas Watson<sup>5</sup> speaking of psoriasis and lepra says: "I believe that they sometimes depend upon the presence, or the generation of an excess of acid in the system; and that they are often cured by alkalin remedies, I am sure."

Prout<sup>6</sup> mentions the alternation of leprosy and scaly skin diseases with deposits of phosphate of lime in the urine, in patients who have been subject to gout and rheumatism, the urinary affection becoming better as the cutaneous affection has become worse, and vice versa.

I have purposely quoted from these older writers, rather than from those of recent date, better known in connection with diseases of the skin, because the tendency of modern specialism has been rather in the direction of the minute study of local lesions, and of the local causes of diseases of the skin and away from constitutional conditions, and consequently the so-called humoral views of older writers have been rather overlooked of late.

These who have been quoted, (and the number could be greatly increased if desired) were general practitioners and teachers of prominence, and all were experienced and accurate observers, and their opinions should have weight in this, as they have in other matters.

These observations, and others made by equally careful and acute observers I can, to a good measure, indorse by my own experience, and many cases in my own practice abundantly confirm their truth. As yet, however, no perfectly well-defined statements can be made as to the precise condition which may be looked for in all cases, even in those which present symptoms which may be looked upon as gouty; but I believe that real advances will be made in proportion as they are recognized and treated.

The urine is often a most valuable guide in the recognition and treatment of the acid state which underlies many cases of psoriasis, and should receive more attention than is commonly the case in the management of this disease. In my recorded observations of the urine of patients with psoriasis, this excretion was seldom such as could be regarded as that of health, and although an analysis of the data does not show any very great uniformity in the deviations from the normal, the changes found were such as one should expect in those functional derangements of the liver and other organs which have to do with the metabolic processes in the system. The specific gravity in them varied greatly, ranging from 1008 to 1040; in relatively few instances was it below normal, and very generally it was much above the normal point, a gravity from 1030 to 1035 being not infrequent; it was common to find a very great difference

between various specimens from the same patient. Albumin was found but once; sugar was not found at all, even in specimens with the highest specific gravities, the increased weight being due to urea and organic salts.

In most of the examinations I have found very decided hyper-acidity, with crystalline deposits of uric acid, urates, oxalate of lime, and occasionally stellar phosphates. The cases which present this acid state of the system well marked are commonly characterized by a congested state of the eruption, often attended with burning or itching, and present a marked contrast to the sluggish and indolent eruption shown by those exhibiting simple debility or the strumous state. It is not possible, as yet, to determine and express the differences presented by those in whom the acidity takes the rheumatic form; clinically they resemble the gouty cases, but often the rheumatic element will be manifested more or less acutely in the joints or otherwise, of which I have known some striking examples.

Whether there is really any difference in psoriasis found in these three commonly recognized states, is difficult to determine. I myself am inclined to think that there is but one cause for the eruption, the acid blood state belonging or leading up to gout; this may be developed more or less in the rheumatic and strumous, as well as in those where its fuller development ends in gouty deposit in, or inflammation of the small joints.

As may be supposed, the treatment of psoriasis will depend very largely upon the recognition of the blood state, or condition upon which the disease depends. While most persons with this eruption will appear to be in perfect health, I believe that there is always some departure from the normal which can and should be discovered and reached if the disease is really to be cured. In many instances the eruption depends wholly upon pure debility, and a prolonged and most careful tonic course will ultimately overcome the difficulty. In the gouty and rheumatic class of cases, undoubted benefit results from a prolonged and faithful alkalin course of treatment, with such remedies as meet the underlying blood state. In many cases a strumous habit will be at the bottom of the trouble, the faulty metabolism being dependent on this, and cod-liver oil, phosphates, etc., will be needed, alternated occasionally with alterative doses of mercury. I do not allude to cases of syphilitic skin lesions, which often closely resemble the eruption in question, for these have nothing to do with it and should never be spoken of as syphilitic psoriasis. A number of writers have reported the cure of psoriasis with full and prolonged doses of iodid of potassium, others have praised antimony, while the number and variety of remedies which have been advocated in this disease are so great that the mere enumeration of them would occupy and waste much time and space; their very number and variety indicate the difficulties attending the treatment of psoriasis, and that there must be causes which are not yet fully understood.

There is certainly no single specific for psoriasis, although arsenic seems to come nearer to this than any one remedy; when given in full and persistent doses it often serves to remove the eruption, and to keep it in abeyance. Arsenic is a very safe remedy, as the drug is eliminated almost immediately from the system, largely by the urine and, as far as I can

<sup>4</sup> Garrod, Reynolds' System of Medicine, Philadelphia, 1868, vol. i. p. 824.

<sup>5</sup> Watson, Practice of Physic, Philadelphia, 1858, p. 1295.

<sup>6</sup> Prout, Stomach and Renal Diseases, Philadelphia, 1843, p. 221.

learn, no ultimately toxic effects occur even from its free and prolonged use. In one instance a patient of mine, a gentleman in whom the eruption began at 22 years of age, took nearly eight ounces of the pure Fowler's solution in a single year; and some time ago he calculated that he had taken over half a gallon of pure Fowler's solution in the course of fourteen years.

But arsenic constantly fails either to remove the eruption or to prevent relapses, nor could we expect it so to do, for the most that arsenic can do is to so control the nerve elements that they shall not be irritated by the acid condition of the blood; when its use is suspended or when it loses its controlling effect, the same condition returns as before. In cases where arsenic has seemed to cure the eruption, the blood state which called forth the skin lesions had probably been of but brief duration, and the arsenic had aided the tissue in returning to the normal.

In psoriasis, therefore, the patient should be studied, rather than the eruption; his diet, habits of life, the state of the emunctories, the condition of the nutrition, and many features which a careful physician notes and takes into consideration in connection with other complaints. My plea is, that one who approaches a case of psoriasis should by no means be content with alone recognizing the local conditions of the skin, and prescribing local measures to benefit them, but that, with broad medical knowledge, he should study the patient and seek to rectify the causes back of the local manifestation on the skin.

Time and space fail to fully develop here the details of this interesting and most important part of our subject, but a few of the most practical matters may be considered.

As may be judged from what has preceded, alkalies should never be neglected in psoriasis. They should not be used sparingly but, taking the urine as a guide, they should be pushed with judgment, and be continued long enough to effect the desired result. Potash, lithia, soda, in various forms and combinations, are remedies of incalculable value in this disease.

But it would hardly be expected that any one remedy or group of remedies would cure a disease which has been such a *bête noire* to the profession; alkalies alone will not accomplish this, but their free use is only urged in connection with other measures. While we know that alkalies are of benefit in gout and rheumatism, we know also that their simple exhibition, without due reference to other remedies, and dietetic and hygienic regulations, will never permanently cure either of these complaints.

In psoriasis, therefore, they must also be given in combination with and alternated with other remedies. Colchicum is often a great aid, and in sthenic cases aconite often assists greatly; prolonged alkaline treatment will often result in more or less anemia, and iron and manganese will also come in as adjuncts, while strychnia, phosphates, cod-liver oil, and many tonics and reconstructives may be needed in fully overcoming the disease.

The proper use of water will also aid in the treatment. The acidity of the urine, as is known, is modified by free dilution, and the changes of assimilation and disassimilation which are at fault in psoriasis, are hastened and improved by the free passage of water through the system. Treatment by means of mineral springs has long been a favorite

one in psoriasis, and undoubtedly many cases have been greatly benefited by the use of medicinal waters of many and various kinds.

One objection to the treatment of psoriasis by means of visits to mineral springs is that, as a rule, these visits must necessarily be short, and while they may possibly be of service at the time, it is impossible in this brief period to so modify the system that the eruption shall not return when the active treatment is omitted; the patient is often thus misled into a neglect of the proper protracted course of treatment which can alone be of permanent benefit. After many visits to many mineral springs, in this country and Europe, I have become more and more convinced that the single element which is of value is the water common to them all. I, therefore, advocate the free use of common water to psoriasis patients taken, as at the springs, hot, and on an empty stomach, a half to an hour before meals. When very convenient to the patient, I also advise visits to mineral springs as an adjuvant, during the summer months, when the regular treatment is apt to be neglected, owing to absence from personal supervision.

But, as in pronounced gout, simple medication will not remove and keep away the disease without aid from diet and hygiene, so in psoriasis these aids are necessary. The effect of a full and stimulating diet is often shown in psoriasis by a rapid increase in the eruption, in its congested and irritable character, and in the freer production of scales; whereas a light and unstimulating diet, with total abstinence from alcohol, will often be followed by an improvement in the eruption. Everything which contributes to the production of an acid state of the system also tends to increase the skin difficulty, and every indulgence in sweets, pastry, fermented wines and beer or spirits may precipitate an attack and will always aggravate the existing eruption.

Excessive meat eating will also increase the disease which, however, will frequently improve with much greater rapidity under the same treatment as before, when the quantity of meat taken is greatly lessened or when it is entirely cut off. I have a considerable number of psoriatic patients who have taken no meat, or only very little fish and white meat of poultry, with the result of being free from the eruption for a long period of time. Fatty matter, however, if properly digested, will aid in removing the diseased state.

Hygiene is also often of importance in psoriasis. This includes proper attention to the clothing worn, to exercise, and to the mode of life. Pure wool should be worn next to the skin, to prevent all chilling of the surface and check of perspiration, which I have repeatedly seen followed by outbreaks of the eruption. Exercise should be moderate, but sufficient to keep the circulation active, and this will often need to be inquired into and directed by the physician, as also the general mode of life, hours of eating and sleeping, etc.; for few patients fully understand or carry out the rules conducive to a perfectly healthy life. A warm and equable climate undoubtedly conduces to the cure of the disease, and raw and damp cold climates, and sudden changes of season, tend to develop and perpetuate the disease. I have known patients to remain quite free from the eruption as long as they resided in the tropics.

The local treatment of psoriasis is undoubtedly very

important; very much can be done by it in the way of more rapid removal of the eruption present, and their use should never be neglected. Many remedies, including chrysarobin, pyrogallie acid, salicylic acid, naphthalin, gallaceto-phenon, aristol and others, all are of great value, and by means of one or the other of them the eruption may often be promptly removed. Bathing of various kinds, including sea bathing, is also of much assistance. But it would lead beyond the limits intended, to consider these in this paper, which is intended to show the importance of constitutional rather than local measures in obtaining the really best results in psoriasis.

The prognosis of psoriasis has always been most unsatisfactory. While all recognize that the eruption may be removed again and again by local treatment, the majority of writers imply, if they do not assert, that the disease is very uncertain of cure; and I find that this view of the case is taken more or less strongly in proportion as the writer emphasized more or less strongly the value of local treatment.

But to return to the remarks made at the opening of this paper: as in the case of syphilis the ultimate cure depends largely upon the intelligence, faithfulness and persistence put into the treatment by both the physician and patient, so in the case of psoriasis, its cure depends upon the same elements.

I believe that psoriasis can and should be cured; but, as in the case of syphilis, relatively few cases are cured so as to never give further manifestations, so in psoriasis it is often extremely hard for the patient and physician to patiently persist in the plan of treatment which will end in a permanent cure.

It is very difficult, indeed next to impossible, to give any statistical presentation in regard to the cure of the cases which have been here analyzed, for in a consultation practice, drawn from many quarters, the patients are so commonly lost sight of and so rarely seen when freed from this trouble, even as in olden time only one of the ten lepers returned to give thanks for his cure. But from a considerable number of cases with whose later history I am acquainted, I feel positive that sufficient knowledge, care and patience on the part of the physician and patient will result in the real cure of this complaint, which has too often been relegated to the now lessening category of incurable diseases.

## PHENACETIN AS A TOXIC AGENT.

Read before the Section on General Medicine of the Texas State Medical Association at Dallas, April, 1895.

BY DAVID CERNA, M.D., Ph.D.

DEMONSTRATOR OF PHYSIOLOGY AND LECTURER ON THE HISTORY OF MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF TEXAS, ETC.

Phenacetin has such a wide range of usefulness as a remedial agent, that it may not be uninteresting to bear in mind some of the toxic effects which the drug is liable to produce. Notwithstanding the fact that phenacetin (with the exception, perhaps of phenocoll) seems to be the least poisonous of the coal-tar derivatives, yet in sufficiently large amounts it may cause serious after effects and undoubtedly, death.

With the collaboration of Dr. William S. Carter, I have carefully studied the physiologic actions of phenacetin in an extended series of experiments upon the lower animals.<sup>1</sup> Dr. Carter and myself did not

notice marked untoward symptoms, even when the remedy was administered in comparatively large doses, nor did we observe any particular changes in the character of the blood itself, changes which, according to other investigators are sometimes produced. Later observations, however, lead me to the belief that phenacetin, especially in large quantities does cause alarming symptoms, chief among which may be mentioned a markedly disordered circulation accompanied with symptoms of collapse. These symptoms have been noticed both in the lower animals and in man.

The fact must not be lost sight of that phenacetin may be adulterated with acetanilid, and other substances, and it is possible that to this adulteration may be due some of the poisonous effects attributed to the drug in question, as reported by various writers. Thus in a case published not very long ago,<sup>2</sup> in which serious symptoms of poisoning were observed, it was found that the powder given as pure phenacetin consisted really of equal parts of this remedy and of acetanilid. Again, Reuter<sup>3</sup> has called attention to the fact that phenacetin contains at times some unconverted parphenetidin, this latter substance producing, even in small doses, toxic effects, especially nephritis with albuminuria.

But be all this as it may, experimental investigation and clinical evidence have shown that phenacetin *per se* exercises a toxic action, particularly when it is ingested in excessive quantities.

Kingsberg and Kast<sup>4</sup> found that large amounts of phenacetin produced in dogs an irregular gait, rapid respiration, vomiting, somnolence, cyanosis and discoloration of the blood, asserting that this latter phenomenon was due to the conversion of hemoglobin into methemoglobin. The same opinion is entertained by Hare<sup>5</sup> in his able essay. Muscular weakness under the influence of phenacetin, probably due to a spinal action, has been observed by Mahnert.<sup>6</sup> Hoppe<sup>7</sup> has reported a case, that of a student, in whom two grammes (30 grs.) of the drug caused insomnia, weakness, inability to stand, and a slight typhalism. Holloper<sup>8</sup> records the case of a woman, who, having taken about a gramme and a half (22 grains) in the course of six hours, showed the following symptoms: great dyspnea, general marked lividity, restlessness, precordial pain, inability to stand, involuntary defecation, dilated pupils, cold perspiration. She finally recovered under the use of ammonia and alcohol. The blueness of the surface of the body, however, lasted for more than three days. For over a week the patient was unable to be around the room, convalescence being very slow. Mahnert<sup>9</sup> has observed urticaria, and Hare<sup>10</sup> has seen large wheals, following the use of phenacetin.

Through the courtesy of a brother practitioner (whose name I have been requested to withhold), residing in a prominent city of the State of New York, I am enabled to report the following highly interesting case of phenacetin poisoning, which seems to corroborate much of what has already been stated in regard to the matter:

A healthy mother who had given birth to two

healthy children, which had thriven and are now living, was delivered early in the year (1895) of a child weighing six and one-half pounds, after a two and a half hours labor. The presentation was R. S. P., the legs extended against the front of the body, the placental insertion low and posterior, as diagnosed before labor by the location of the round ligaments and confirmed by the clean cut hole in the membrane close to the placenta found after delivery. A large amount of liquor amnii was present. The child was very rapidly expelled by pressure on the fundus; the delivered parts were enveloped at once in flannel, without traction; the flexed arms were slipped out readily; complete flexion of the head was maintained by pressure through the abdomen and on the face, so that no traction was made on the neck (Wigand-Martin method) and the funic pulse was certainly not arrested two minutes up to the time when the mouth was brought up to the vulva, swept clean, and the child began to breathe. Then the head was very slowly shelled out. At no time was much force required, at no time was the child cyanotic, and at no time was there any indication of convulsive movement or attempt at respiration before birth. A good pink color, regular respiration and heart action, were present from the first, so that it is not in the least likely that cerebral or spinal injury, or inhalation pneumonia, could have accounted for the subsequent cyanosis. The child did well until its fifth day, losing less than half a pound. On the fifth day a slight diarrhea developed, without temperature and without sepsis from the navel, which sloughed off that day. Three grain bismuth powders three or four times a day were ordered for the diarrhea. They were in a pink box which had been used for the other child, about a year old at this time. On the sixth day, four of the powders were given, making seven in all, the diarrhea ceasing. On the night of the sixth day the baby was very fretful and somewhat weak, and purplish in color. On the seventh day the eyeballs were jaundiced, color dusky, and the child restless, but otherwise her actions were entirely normal except for some hebetude. The digestion was good, the pulse of fair quality—130 to 140—the temperature in the rectum, respiration, and pupils normal; but on the seventh and eighth days the lips and finger nails were black and the extremest cyanosis was present. On the eighth day, Prof. Charles Jewett went over the case carefully, confirmed the statement that the lungs were entirely clear, and found nothing whatever to account for the condition. On this day bloody urine in large quantity was passed. The prognosis was very bad and the child looked as if it could live but two or three hours at most when seen by Professor Jewett. Without much hope, oxygen was ordered. On the ninth day it was seen that during the night, after about the fourth application of oxygen (ten minutes out of each half hour) that the color had somewhat improved with each administration, and the action was distinctly soothing. The stools on this day became of a coffee color, the temperature  $100\frac{1}{2}$  degrees F., and the baby, as always nursed well.

From this time on the baby had ups and downs, the cyanosis continuing but never as grave in degree. The case had practically no history except the cyanosis of varying intensity. The oxygen was efficient for only two days. On the eleventh day the promise was brighter, the child not pink, but the duski-

ness distinctly less, though from this time on marked jaundice was present, with less color in the urine, anemia of a very high degree, and pronounced weight-loss. The pulse about this time was weak for a couple of days, at no time above 150, and the temperature never above  $100\frac{1}{2}$  degrees F. Before the thirtieth, the original weight was regained, and by the fiftieth the anemia was nearly gone.

Just after the consultation, the physician, author of the foregoing report, found two powder boxes of exactly the same appearance; one labelled, "for baby's diarrhea, three or four times a day," and the other labelled, "For the other child's fever and pain—not over three a day." The nurse then found that she had given seven 2 grain doses of phenacetin, instead of seven 3 grain doses of bismuth; on the first day, 6 grains, on the third day 8 grains, and that it was on the night subsequent to the last dose in the evening, that the cyanosis began.

Somewhat elaborate details concerning the delivery, etc., have been given in order to show that no injury during delivery, or other cause, could explain the condition of the little patient adequately. It was, undoubtedly, a pure case of phenacetin poisoning.

No comments seem necessary on the above report. It may not be out of place in this instance, however, to recall the observations of Reuter<sup>11</sup> regarding parphenetidin which phenacetin sometimes contains as an impurity, and which, it is believed, causes toxic effects even in small quantities. The author just referred to gives the following method for the detection of parphenetidin in phenacetin; "2.5 grammes ( $38\frac{3}{4}$  grains) of chloral hydrate are melted in a small test-tube on a water-bath, and 0.5 gramme ( $7\frac{3}{4}$  grains) of phenacetin added. Upon shaking, a solution will be formed, and if the phenacetin be absolutely pure the solution will remain colorless for at least five minutes, but after that time will assume a rose-red color. If, however, the parphenetidin be present, and it be exposed to the same temperature on a water-bath for not more than two or three minutes, the solution becomes colored, according to the quantity of contamination present, into more or less intensely violet, varying from a red violet to a blue violet."

In conclusion, I may be allowed to remark that in cases of poisoning by phenacetin, cardiac and, more especially, respiratory stimulation by drugs would be useful. The results obtained in the case herein reported, in which oxygen inhalations seemed to do well, and in that reported by Hollopter, in which stimulation by ammonia and alcohol acted efficiently also, are self-explanatory. In a given case, prolonged artificial respiration as a last resort would seem to be particularly indicated.

#### AN AURAL MASSEUR.

BY CHEVALIER JACKSON, M.D.

PITTSBURG, PA.

The accompanying illustration shows an instrument which has yielded me splendid results in the treatment of non-purulent middle-ear disease during almost three years. Until I devised it, I scarcely knew what to do with the class of cases that come with a story something like this: "Doctor, I came to see if you could do anything for me. I am hard of

<sup>11</sup> Loc. citat.; also *Annual of the Universal Medical Sciences*, 1892.

hearing and have annoying noises in my ears. I am told that both my throat catarrh and Eustachian catarrh have been cured. My general health is good. Yet my trouble is growing worse. I have a bag and have Politzerized myself until I am sick of it. I seem to have gotten all the benefit that it will yield me. Can you do anything for me, Doctor?"

I had often been at "my wits' end" trying to suggest or do something that had not already been suggested or done in such cases. But for nearly three years past I have been able, with the aid of the instrument illustrated, to get results that seemed marvelous considering the obstinacy and chronicity of this class of cases.

The action of the instrument is practically on the principle of pneumatic massage. I used to apply pneumatic massage by means of either a Sieglé speculum or a bit of rubber tubing—in either case operated by the mouth; rather an indelicate procedure. Then I tried operating them with a syringe. I have also used the Delstanche. But with none of these did I get anything like the results that I have since obtained from the use of this masseur.

Its construction and operation will be readily understood from the following description, by reference to the cut: it consists essentially of a cylinder oscillating on a central pivot, and within this cylinder a piston moved up and down, by being connected with a revolving crank disk. Motion is imparted to the masseur by a small electric motor run by a battery, storage cell, lighting circuit or other source of electricity. It might be operated by a crank arrangement. A rubber tube leads from the bottom of the cylinder and ends in an ear piece to be inserted in the external auditory meatus of the patient. When the instrument is set in motion, the moving up and down of the piston within the cylinder causes a to-and-fro motion of the column of air confined in the tube and meatus, resulting in a to-and-fro motion of the membrana tympani and ossicula. And if we start on the exhaust stroke, with the plunger down, the first half of each revolution of the crank disk will draw the membrana tympani outward, and the second half of each revolution will release it and allow it to resume its former position. When operated in this way, by starting on the exhaust stroke, the result is not simply the to-and-fro motion of the membrana tympani, but is an alternate withdrawal and release. Considering the pathologic conditions present, to this may be attributed the very much better results from this instrument than are obtained from the Delstanche or Sieglé. However, be the true reason what it may, there can be no question as to the fact that the results are better. The ear piece is placed at an airtight fit into the meatus, and the energy of action regulated by placing the crank pin in one or another of the holes in the crank disk. These holes vary in the distance of their location from the axis of the shaft;

the farther the crank pin from the axis, the longer (therefore the more energetic) the stroke. The energy of action could be regulated by making a more or less tight fit of the ear piece in the meatus, but if this is resorted to the exhausting action is lost and this I think, is a disadvantage. A very mild action has given me the best results.

It has seemed most advantageous to apply the masseur every alternate day, sittings of thirty seconds to a minute duration, the masseur making from one hundred to one hundred and fifty revolutions to the minute. Knowing well how treacherous is enthusiasm I have refrained from publication until the instrument had been fairly and faithfully tried and the permanency of the results observed. As this has covered a period of two years and ten months, the present writing will seem not unduly hasty and the results entitled to be considered mature.

The word "benefited" is meant to include both relief of tinnitus and increase of hearing distance. In many cases the relief of both these symptoms was so marked and so immediate from a single sitting that the patient was greatly delighted. In some cases the results were but slight at first and increased at each subsequent sitting, while in other cases the benefit only appeared after a number of applications. Psychic effect was marked; patients were fascinated. But great care was taken to eliminate error from this in the records, which are of the cases of my own and those of Shirls Jackson.

Here is a resumé of my results:

Total number of ears treated . . . . .	100
Number of ears treated that were better than c.34 . . . . .	61
Number of the latter benefited . . . . .	46
Number that could only hear watch on contact . . . . .	39
Number of the latter benefited . . . . .	19
Percentage of benefit in cases better than contact . . . . .	.75
Percentage of benefit in cases not better than contact . . . . .	.48
Percentage of benefit in all the cases . . . . .	.65

Cases that could only hear on pressure, not on mere contact, were not isolated in the records.

Unlike Politzerization the application is not disagreeable to the patient and is readily applied to any one, regardless of the ability to swallow water at command. Children do not object to its repetition, and it has yielded good results in a few cases when promptly used in ear trouble following acute diseases.

Taking it all in all, my results have been much better since adding this instrument to my armamentarium.

## EXPERIENCE OF AN AMERICAN PHYSICIAN IN MEXICO.

BY D. H. GALLOWAY, M.D.  
CHICAGO.

*A Case of Cancrum Oris.*—One day happening to be in the dispensary conducted by Dr. Salmans, in Silao, I saw a child brought in which the Doctor had no sooner seen than he exclaimed: "Take it away! It will die!" Although I had never seen a case of cancrum oris, it was scarcely necessary for him to name the disease. The appearance and odor were something frightful, and death was then but a question of a few hours. When the Doctor had finished prescribing for the thirty or forty patients waiting, I asked him about the disease. He told me that in some two years' practice in that state, he had seen eight or ten cases of this dreadful malady; that he did nothing more than tell the people that the disease would be fatal, and dismissed them. He also

informed me that the Mexican doctors pursued the same course. This was not so much from a belief that the disease was incurable, as from the fact that the people among whom it occurred were too poor to pay for treatment, and too indifferent and ignorant to coöperate energetically or intelligently with the physician in its treatment. My duties in the medical service of the railroad company were sufficiently light to leave considerable time at my disposal. I requested the Doctor to turn the next case over to me, and if much deformity had not already been caused, I would attempt its cure. In most cases a large amount of tissue had been destroyed before the doctor was consulted. In such cases the chances that any treatment would stop the course of the disease are very slight; moreover, when such deformity had already been produced it would seem inhuman to try to save the child's life, for such a child would be a constant source of misery to itself and all about it as long as it lived; where the over-production of babies is so great that even the vigorous and healthy can not get enough to eat, the maimed will fare badly indeed.

September 6 I was again in the dispensary, when a woman brought in a child, a glance at whose face and a whiff of the horrible stench which preceded it, being sufficient to identify it as a case of cancrum oris. The Doctor told her to take the child out of the room, that it would die. Tears filled the mother's eyes as she left the room; this unusual exhibition of feeling reminded the Doctor of my offer, and he suggested that this would be a good case to begin on. I followed the woman outside and told her that if she would do exactly as I should direct, that I would undertake to cure the child. To this she readily agreed. The boy's name was Juan Sanchez, and he was 2½ years old. Like all of this class he was fearfully filthy, and I instructed the mother to take him home, give him a thorough scrubbing, from head to foot, and bring him to my office. This would not only make him a little less loathsome to handle, but would also be an earnest of her desire to have him live. In a short time she appeared at my office with the boy cleaner, probably, than he had ever been before or would ever be again. I placed two chairs facing each other, outside of the door, gave her one and I took the other. I had the mother hold the child on its back in her lap, in such manner that she could perfectly control its hands and feet. I then took its head between my knees, as in a vise, first covering my knees with a newspaper that I might be less likely to infection by pediculus capitis.

The disease had started around the upper central incisors. The upper lip was edematous, so that it projected beyond the point of the nose; the swelling extending to the cheeks. The blackening had not involved the lips, but extended for a considerable distance on both sides of the teeth. With a pair of dissecting forceps I removed the two teeth and scraped away the blackened portion. As I did so the connective tissue strung out like hair. Then I took an absorbent cotton wad on a toothpick, dipped it in strong nitric acid, canterized the discolored surface, and in a few minutes washed it with water. I then dismissed her with instructions to come to the office every morning. The next morning, Sept. 7, I treated it with a saturated solution of copper sulphate in water. Blackened spots had reappeared, and these I picked out with forceps before using the wash.

September 8 I removed the rudiments of the secondary set of teeth and a portion of the alveolar process, used strong nitric acid and followed with the copper solution. On the 9th I repeated the copper sulphate treatment. Pus was coming from the nose in great abundance. September 10 the child first began to show signs of improvement, and from this time on it slowly became better, under the use of the sulphate of copper every day. The edema gradually lessened and some effort toward repair of the damage was apparent. Nearly every morning I found one or more black spots, like pin heads, and this treatment was continued twenty-two days. For several days no blackening was to be seen and the wound was covered with healthy granulations.

I did not see the case for four days, and then found the cavity almost completely filled up, mucous membrane had formed over it all, and the only mark left by the disease was a cleft through the alveolar ridge, probably one-sixteenth of an inch wide, having something the appearance of a cleft palate. To me, the most remarkable thing about the case was the filling-in of the dental arch as perfectly, excepting the slight cleft, as it had been before the teeth had first made their appearance. I was absent from the city for a month, and on my return was unable to find the patient. I was anxious to know whether the cleft became smaller. I do not believe it would ever entirely close up. The boy would never have any upper central incisors.

#### ECTOPIA TESTICULI.

BY JNO. MADDEN, M.D.

MILWAUKEE, WIS.

The drawings herewith submitted are to illustrate a case of, and an operation for the excision of an ectopic testicle, made by the author on March 4 of the present year. The patient is a young man, 22 years old. Four or five years ago he first noticed a bulging at the left external abdominal ring which was accompanied by a dull pain extending to the loins and back. For one, two or three weeks the bulging would disappear, during which time he felt no discomfort.

An examination of the part while the tumor was present, disclosed only the presence of a mass of soft tissue in the inguinal canal, in the midst of which could be felt a cord which was taken to be the spermatic cord. The conclusion was therefore reached that the testicle was within the abdomen, its descent prevented by the smallness of the internal abdominal ring, and that the cord felt was the spermatic cord bent upon itself, the testicle presenting head foremost at the internal ring. An operation was advised, either to bring down the displaced organ and secure it within the scrotum, or, in case this was found impossible or impracticable, to remove it altogether.

On cutting down into the inguinal canal some difficulty was experienced in getting hold of the "cord," for the tumor was not then presenting. It was finally reached, however, and drawn down, when a small testicle appeared just without the internal ring, firmly held by a cord behind it. It was then discovered that the supposed cord in the inguinal canal was the epididymus, which, with one end attached to the testicle, trailed down the inguinal canal (see Fig. 1). The real cord of the testicle proved to be so short that it could not be pulled far out of the internal ring. It was therefore ligated with

double ligature and cut off close to the testicle. Fig. 2 is a drawing made from the object and very accurately represents the parts removed.

The wound was closed with the continued (etage) catgut suture (Fig. 3), embracing all of which were five stout interrupted silk sutures. (Fig. 4). Nothing disturbed the patient's convalescence.

It should be remarked that the right testicle of this subject is in the normal position, and seems to have reached a development compensating for the lack of development in the displaced organ.

In 1887 the author removed a very large testicle from the inguinal canal of a young man 19 years of age. This was also on the left side. A microscopic examination showed the organ to be the seat of very extensive sarcomatous degeneration. This patient

FIG. 1—1. Internal ring. 2. Testicle. 3. Epididymus. 4. Prolongation of abdominal peritoneum making "tunica vaginalis."

died of exhaustion about six weeks after the operation, and a post-mortem revealed enormous sarcomata of the supra-renal capsules.

In recent years the literature of this subject has become quite extensive; but still there is not enough material at hand to establish any well-defined rules of surgical procedure. Indeed, it is more probable that each case will continue to present a distinct problem, to be solved according to the nature of the

FIG. 2—A. Testicle. B. Cut surface where end was severed. C. Tunica slipped back. D. Epididymus (natural size).

surrounding conditions. If, as some operators seem to think, the atrophied ectopic testicle would develop after being brought into a normal position within the scrotum, a good deal of effort should be made to accomplish this object. The most favorable report I have been able to find, in which the object of the operation was to replace (or rather transplant) the ectopic organ in the scrotum is that of Jalaguier (*Le Bulletin Medical*, Paris, March 5, 1894). He reports fifteen cases in thirteen subjects. Herniæ co-existed in six cases. In two "the testicles became normal in size in from thirty to thirty-six months." In twelve others, at the end of three to fifteen months, the organs were "movable, sensitive, of normal consistency, and showed no disposition to retract." This

author is of opinion that, in retained testicle, there exists a fibrous band connecting the testicle with the cribriform fascia and confining it. He advises operation in all cases where the subject is over 5 years of age, and in cases connected with troublesome herniæ.

Terillon (*Le Bulletin Medical*, March 8, 1894) reported six cases, congenital hernia in four, operated on by himself. In three cases "result was satisfactory." In one, the testicle retracted to its former site, and in two atrophy took place.

FIG. 3—Etage Suture for obliterating Inguinal Canal. A. Closing wound.

W. Von Schuttler, of Finland, (*Lyons Medical*, Lyons July 16, 1894) reported two cases operated on by him, one and a half years ago, in which the result was good. In two other cases (date of operation not given) he performed castration because the displaced testicle could not be fastened in the scrotum. In all of his cases hernia existed, and, in one of them, the hernia was strangulated.

FIG. 4—Sectional view Etage and Interrupted Sutures.

Guibert of Reims (*Annales des Maladies des Organes Genitourinaires*, March, 1894) reported a case of abdominal ectopia of both testicles in a boy of 18, upon whom he operated a year before, bringing one of the displaced organs into the scrotum. At the time the report was made, the subject was said to have "one good testicle in the normal position, normal erections and emissions in which there were some good sper-

matozoa, while others were deformed and broken." As the condition of the subject in respect to erections and the nature of the semen before the operation is not given, this evidence of improvement is not very valuable.

Felizet (*Le Bulletin Medical*, March 12, 1894) makes the observation that "when the organ is movable, it is generally normal in form, volume, and consistency and will descend if enlargement of the inguinal canal takes place; but when fixed is usually altered in size and texture and is painful." My own recent case contradicts this statement; for this testicle was freely movable but very much atrophied and painful.

At a meeting of the London Medical Society (*Lancet*, April 16, 1894) Mr. C. B. Keetley reported two cases upon which he operated to bring the testicle within the scrotum. In one of these cases he was unable to bring the organ down far enough to fasten it in the scrotum. He had therefore made an incision in the thigh, opposite a corresponding incision in the upper part of the scrotum where the testicle was fastened and covered by uniting the scrotum with the thigh. In this position it was allowed to remain five months. It was then brought down and fastened in the scrotum where it remained. A discussion arose as to whether an atrophied ectopic testicle would grow when artificially transplanted in the normal position. Mr. Keetley replied that the organ had "already grown."

In 1890 (*Lancet* February 1), Mr. Watson Cheyne reported two cases in the same subject. In this case the testicles were lying in the inguinal canal, "but could be made to come down through the external ring." The right side was operated on a year before by suturing the testicle to the bottom of the scrotum and closing the external abdominal ring, passing some of the sutures, used to close the ring, through the cord and skin. The result was fairly satisfactory. Ten months after, the left side was operated on. In this case, the surgeon passed a silk ligature through the cord above the testicle, brought it through the bottom of the scrotum, and tied it to a bar of wire projecting from a frame made fast to the perineum. The stitch was removed on the eleventh day and the testicle remained in the scrotum.

Of the American cases we find one reported by E. A. Balloch, of Washington, D. C., *Medical Record*, August 6, 1892). In this patient who was 47 years old, one organ was removed in 1889 and the other in 1891 for "painful orchitis."

Dr. O. L. Bartlett of Rockland, Me., operated successfully in 1892 on a subject in which the left testicle was invisible and the right in the inguinal canal. The right gland was put in its proper locality and "sexual power was perfect." Hamilton Williams, M.D., of Brooklyn, reported (*Medical Record*, Dec. 7, 1889) a case of sexual hypochondria in a subject, in which there was an absence of the right testis, while the left was in the inguinal canal. An operation upon the left was attended by success in all respects. Dr. Gerster, of New York, reported a case in 1886, in which ectopic testicle was a complication of hernia; castration was performed and the testicle was found to be sarcomatous.

Two considerations must influence our judgment in deciding what is best to be done in dealing with this class of cases. Investigation has shown (see article of H. Royes Bell in "Int. Ency. of Surgery") that the ectopic testicle is not productive of virile

spermatozoa. To this rule there seems to be but few exceptions. The second consideration is the liability of the retained organ to undergo destructive inflammation or malignant change. Of the thirty-six cases mentioned in this paper, two were removed because of long standing orchitis, and two were the seat of sarcomatous degeneration. Thus 11 per cent. of the ectopic organs were the seat of destructive disease. It would seem, then, that in subjects possessing one healthy gland normally situated, the atrophied and useless testicle should be promptly sacrificed.

In case, however, both testicles are retained, the justice of adopting measures for their preservation is apparent. Should it finally be demonstrated that an ectopic aspermatozoic testis may become virile when put in its normal place, there will exist sufficient reason for making every attempt to do so.

## ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 669.)

### CHAPTER X.

*Case 2.*—Yellow fever, black vomit, death. John Sullivan entered Charity Hospital Oct. 8, 1873, about fourth day of disease, great congestion of capillaries of face, neck and extremities, jaundice, hiccough, nausea, pain in head especially in frontal region. Pulse 82, respiration 28, temperature of axilla 98.2. October 9, 8 A.M., pulse 72, respiration 28, temperature 97.1; black vomit. The liquid ejected in abundance is of low specific gravity and strong acid reaction and contains numerous dark specks and flakes resembling coffee grounds. Hands feel cold. Great congestion of peripheral capillaries. Jaundice; conjunctiva of eyes congested and yellow; tongue red at tip and edges. Gums very red with some oozing of blood. Patient says that he has pain everywhere. Urinary excretion suppressed. 8 P.M., pulse 80, respiration 30, temperature 99.2. Spits up black vomit all over the bed.

October 10, 8 A.M., pulseless, respiration 40; temperature 92.2. Suppression of urine. Patient restless and delirious. Spits up black vomit which resembles black liquid blood. Died at 10 A.M. Temperature of axilla at moment of death 99.2. There was no rise of temperature after death. Examination of black vomit; clear straw-colored liquid, holding in suspension dark coffee-ground-looking flocculi and flakes resembling coffee grounds, which settled to the bottom of the vessel, when the liquid was allowed to remain at rest. Reaction strongly acid. The reaction was found upon analysis to be due to acetic and hydrochloric acids. Under the microscope, I observed broken capillaries, cells of mucous membrane of stomach, blood corpuscles and angular masses of hematin and cells of the gastric mucous membrane stained with hematin. Numerous bacteria and retating animalculæ, about one ten-thousandth of an inch in diameter rapidly appeared and increased in numbers. Specific gravity of black vomit 1004. When filtered, the colored blood corpuscles, masses of hematin, and mucous cells remained on the filter, and a clear, light, straw-colored liquid passed through. The filtered liquid gave a heavy precipitate with nitrate of silver, and a mere turbidness with the chlorid of barium. Nitric acid produced no precipitate in the filtered liquid. The graded solution of the nitrate of the per- (red) oxid of mercury used in the analysis of the urine after the method of Liebig produced a heavy white precipitate from the presence of urea. The usual process for urea in the blood and organic liquids revealed the presence of urea. This specimen of black vomit was collected October 9 at 10 A.M. Upon carefully tasting the black vomit I found it to be decidedly bitter like bile, although I was unable by chemic tests to detect either the coloring matter or the acids of bile. The black vomit be-

came thicker toward the close of life, and more nearly resembled dark grumous blood. During the last thirty-six hours of life, this patient emitted a foul stench, and presented a horrible appearance, with the dark filthy stains of black vomit on the bed-clothes, and even the sides of the walls; streams of black vomit running from the corners of his mouth, and immense swarms of flies hovering over and around his bed.

Post-mortem examination: results similar to those recorded in many other cases of yellow fever already presented in detail.

*Case 3.*—Yellow fever, black vomit, death. Daniel McMonagale, age 18, native of Ohio, left his native State two years previous to the present attack; resided in Memphis and Vicksburg, and has been in New Orleans two weeks. Has had chills and fever at various times during the past two months. Entered Charity Hospital evening of Oct. 11, 1873. I saw this patient for the first time on the morning of October 12, 8 A.M. At this time, although not actually delirious, is unable to give a full and accurate account of his present attack. Surface of body covered with petechiæ. Gums red. Tongue very red at tip and edges. Body of tongue coated with light yellow fur. Tenderness on pressure of epigastrium. Conjunctiva of eyes injected. Center of tongue cracked, with dark blood oozing from the denuded surface. Conjunctiva of eyes and surface of body present a distinct yellow color. Nausea; pulse 110, respiration 22, temperature of axilla 104.6. 8 P.M., pulse 113, respiration 26, temperature of axilla 105.5. The pulse has increased two beats, the respiration four, and the temperature of the axilla, 0.9 F. Has ejected the matters contained in the stomach, with some flakes and streaks of dark blood. A small amount of urine was collected during the day which contained bile, albumin and urinary casts. The urinary secretion is scant and evidently diminished in amount. Injection of ice-cold water into the rectum was ordered; ice bag to epigastrium, and water charged with carbonic acid, iced milk and fragments of ice internally.

October 13, 8 A.M., pulse 110, respiration 29, temperature 104.5. Dull and stupid. Has thrown up black vomit in considerable quantity. The injection of the ice-cold water appeared to be beneficial and to increase the flow of urine. 8 P.M., pulse 112, respiration 34, temperature of axilla 104.7. Continue ice-cold injections to rectum and treatment. October 14, 8 A.M., pulse 116, respiration 35, temperature 103.3. Delirious; jaundice; great capillary congestion; urine scant. During the night the patient discharged black vomit over his bed and against the sides of the wall. At the present time, spits up black vomit against the wall, like tobacco juice. The black vomit appears to come up without any effort. The nurse found it almost impossible to collect the black vomit for microscopic and chemic analysis. No urine has been collected since the first day, although the nurse states that the patient has passed it in bed. The injection of the rectum with cold water appeared to produce beneficial effects upon the congested and embarrassed kidneys. 8 P.M., pulse 130, respiration 38, temperature of axilla 103.3. Great capillary congestion, conjunctiva and surface of a yellow mottled appearance. Petechiæ have continued upon the surface. Notwithstanding the increase in the rapidity of the pulse and respiration, the temperature has fallen 2.2 F. since October 12. Died October 15 at 6 A.M. This patient was delirious for thirty-six hours before death.

Autopsy three hours after death: exterior of body of a golden jaundiced color; lower portions of a deep purplish mottled appearance. Black vomit issuing from corners of mouth and streaming down the neck. Limbs, trunk and face full and plump. Blood issuing from both ears. Thorax: lower portions of lungs congested, otherwise normal. Heart: muscular fibers presented a yellow appearance and were much softer than in healthy hearts, and in the heart of malarial fever. Under a magnifying power of 450 diameters the transverse striæ of the muscular fibers were found to be indistinct, and to be filled with granular matter and small oil globules. The granular matter and small oil globules appeared to be deposited around as well as within the muscular fibrillæ. The blood from the cavities of the heart was carefully collected; it was still warm, and fluid. Upon standing a few min-

utes in the glass vessel it coagulated. Under the microscope the vast majority of the colored blood corpuscles presented a normal appearance; a few presented a crenated stellate appearance. The blood corpuscles ran together, forming rouleaux as in the blood of inflammation. The fibrin was diminished in amount—the clot was voluminous and soft, but the fibrin was in larger amount, and the clot was more firm than in those cases in which there had been complete suppression of the urine. Upon careful examination, with a high power, 1-18 of inch, I discovered no bacteria, animalculæ nor fungi in the blood. The blood, however, contained numerous oil globules. Reaction of blood neutral or very slightly alkaline. Upon standing for a few hours, golden-colored serum was pressed out of the clot, which also contained colored corpuscles. At the end of three days the clot still remained undissolved. The serum was less deeply colored than in those cases in which there was complete suppression of urine. The liver upon the exterior presented a yellowish mottled appearance. This appearance was also observed when sections of the organ were made, and appeared to be due to the congestion of the hepatic capillaries within each lobule. The periphery of each lobule, including the portal system of capillaries, was of the usual yellow color, and the oil appeared to be accumulated in largest amount in this portion of the lobuli. Some portions of the liver were without any marked capillary congestion of the hepatic venous capillaries, and presented a uniform yellow appearance. This liver in a general view, presented more nearly the Spanish brown color of the liver of health than in many cases of yellow fever; and this depth of color was due to two causes: 1, to the great congestion of the central capillary (hepatic capillaries) of each lobulus; and 2, to the presence of dark granular masses of hematin, scattered chiefly through the portal system of capillaries, and which had evidently been deposited during the preceding attack of malarial fever. The blood was much brighter in color in the capillaries of the liver than in malarial fever. The blood from the cavities of the heart and from the blood vessels of the liver also changed to a bright arterial hue. The voluntary muscles, as those of the thorax, presented a brilliant hue when exposed to the atmosphere. The muscular fibers of the heart on the contrary presented a distinct yellow color like that of the liver. The gall bladder was entirely empty, kidneys of a yellowish color and congested. Sections of the kidneys with Valentin's knife were carefully examined with magnifying powers ranging from 1-2 to 1-18 inch objective. The Malpighian corpuscles and tubuli uriniferi contained detached cells, oil globules and yellow granular matter. These matters have accumulated to a much less extent, however, than in the kidneys of those cases of yellow fever in which there had been complete suppression of urine. Urinary bladder distended with golden orange-colored urine. Specific gravity 1012; reaction acid; urine contained albumin in considerable amount with detached cells and casts; no grape sugar. Alimentary canal, mucous membrane of stomach congested, with denuded patches, in which the ends of broken vessels filled with dark liquid blood were plainly seen, especially when low magnifying powers were employed. The stomach contained eight fluid ounces of thick, grumous, almost black liquid blood or black vomit. Under the microscope, the contents of the stomach

contained numerous blood corpuscles variously altered in their forms, masses of hematin, mucus corpuscles, broken capillaries, detached epithelium from mucous membrane and granular casts of the glands of the mucous membrane of the stomach. No animalculæ or vegetable organisms were observed in the black vomit. Some oil globules were observed, which were referred to the milk which the patient had taken before death. The black vomit emitted a foul putrid odor as of decomposed blood. Reaction of black vomit slightly acid. Spleen, enlarged, softened and exhibited the marks of preceding malarial fever.

The foregoing investigations occupied my time fully for twelve hours without intermission. I determined to institute a series of experiments with black vomit upon living animals, and at 6 P.M., Oct. 15, 1873, I instituted the following experiments:

EXPERIMENTS UPON LIVING ANIMALS WITH THE BLOOD FROM THE HEART, AND THE BLACK VOMIT FROM THE STOMACH, OF YELLOW FEVER CASES.

Experiment 305.—With a small "subcutaneous" syringe, I injected beneath the skin of a healthy puppy, about thirty drops of blood taken from the heart of a yellow fever patient three hours after death. No ill effects were observed.

Experiment 306.—In like manner I injected beneath the skin of an active guinea pig about the same quantity of blood from the yellow fever heart. The next day, Oct. 16, 1873, the guinea pig appeared lively and ate its food. October 17, the animal appears sluggish and refuses food. October 18 animal feeble; moves with difficulty, and is evidently ill from the effects of the injection. October 19, 5 A.M., I found the guinea pig dead, cold and stiff.

Post-mortem examination.—Body emits a disagreeable odor; cellular tissue of skin and surface discolored and greatly congested around the point of the injection of the yellow fever blood. Cellular tissue and skin softened in those portions around the area of injection. Under the microscope the fluid from these portions of the cellular tissue was found to contain bacteria and revolving animalculæ. Cavities of the heart distended with dark, almost black, loosely coagulated blood. Blood changed rapidly to the arterial hue upon exposure to the atmosphere. Under the microscope the blood corpuscles presented no peculiar alteration. Liver congested. The microscope revealed no accumulation of oil in the textures of the liver. Liver cells distinct but pale. No bacteria, or animal or vegetable organisms were observed in the blood of the heart, or in the blood and structures of the liver.

Experiment 307.—Into the subcutaneous tissue of a large, healthy and active male guinea pig, I injected about thirty drops of black vomit, taken from the stomach of the yellow fever patient three hours after death. The black vomit thus carefully injected into the cellular tissue caused the death of this animal in six hours.

Post-mortem examination.—Diffused redness, and great capillary congestion of cellular tissue beneath the skin. Congestion greatest in the immediate vicinity of the injection. Body emits a foul putrid odor. Immediately around the point where the black vomit had been injected dark blood had been effused, and the textures presented precisely the appearance of those wounded and poisoned by the fangs of the rattlesnake or copperhead. The cavities of the heart

were distended with dark loosely coagulated blood. No animalculæ, bacteria or fungi, or algæ discovered in the blood. Decomposition rapid; and although the animal was examined almost immediately after death, the odor was disagreeable and resembled that of the black vomit.

Experiment 308.—I injected into the subcutaneous tissue of a large healthy guinea pig, about thirty drops of black vomit which I had preserved from a case of yellow fever, ejected shortly before death on Oct. 9, 1873, six days before the present experiment. Death caused by the black vomit in six hours.

Post-mortem examination.—Results similar in all respects to those recorded in the preceding experiment; intense congestion of cellular tissue around locality of injection of black vomit; no animalculæ or vegetable organisms in blood; putrefaction rapid and marked by foul odor.

Experiment 309.—I injected into the subcutaneous tissue of a guinea pig about thirty drops of putrid blood, which I had extracted from the cavities of the heart of a subject who had died six days before, on October 9, in a "congestive" malarial chill. Death caused by the putrid malarial blood in eight hours.

Post-mortem changes similar to those recorded in experiments third and fourth.

The preceding experiments are of importance in establishing the fact that black vomit, taken from the stomach immediately after death, or ejected during life in yellow fever, will, when injected into the subcutaneous tissue, produce as deadly and as rapidly fatal results as putrid blood.

We deduce the following practical conclusions:

1. Black vomit, when absorbed into the circulatory system, may act as a deadly septic poison.
2. As the capillaries of the stomach in yellow fever are often ruptured, and the epithelium of the mucous membrane denuded, it is possible that in some cases the absorption of black vomit, especially after it has undergone putrefactive changes in the stomach, may be an important cause of the fatal issue.
3. If remedies could be used which would prevent putrefactive changes in the black vomit and render it comparatively inert, a certain proportion of cases might be rescued, after the appearance of black vomit.

The preceding experiments and reasoning led me to employ the sulpho-carbolate of sodium, in doses of 20 grains, every four or six hours in the treatment of yellow fever. I have used the sulpho-carbolate of sodium in about forty cases of yellow fever, with satisfactory results. I find that it is readily borne by the stomach at all stages of the disease; that so far from exciting nausea or vomiting, it often modifies and arrests these distressing symptoms. It appeared in some cases to arrest the decomposition of the black vomit. One case accompanied by a temperature of 107.1 degrees, and attended with black vomit recovered under its use, combined with ice-water injections into the rectum. At some future time we hope to present statements of these cases.

Davaine claims to have made the following discoveries: after injecting beneath the skin of an animal's neck a single drop of putrid blood, the surrounding tissue became extensively infiltrated, and death soon followed with symptoms of septicemia. The blood of this animal was then employed to inject other animals in a similar way, and was found to be more poisonous than the original putrid blood. A

third and fourth animal was then injected, each with the blood of the preceding one, and in this way twenty-four in all were experimented on. The results seemed to show that the toxic power of the septic material increases by dilution.

Stricker, in a series of experiments undertaken to test these statements, inoculated 25 animals with healthy, 23 with putrid, and 73 with blood diluted by transmission. Of the first series, 4 died. Of the second series 11 died. In experiments with diluted blood, when it had passed through 13 different animals, 53 of the 73 died. From this it appears that even the very small amount of 1-1250 of a cubic centimeter of poisonous material could cause death when injected hypodermically. Davaine's statement that organisms form in the blood and increase by every transmission, was not sustained by investigation. Stricker found numerous colorless bodies in the blood of these animals, but he did not regard them as organisms, but rather as protoplasmic bodies. The following facts he regards as ascertained:

1. That transmission greatly increases the injurious and fatal action of the putrid matter.
2. That the original disease was infectious, but that through inoculation it became contagious.
3. That though it be not proved yet it is probable that the special poison is a living contagion (*contagium animatum*) for such rapid proliferation is only possible in organized material.
4. That the poison is diffusible and is not destroyed by boiling (*Allg. Wein Med. Zeitung*, 20, 1873; *New York Medical Record*, July 1, 1873, p. 311).

If it be true that the poison of yellow fever may be generated in human beings under certain conditions of the constitution, and more especially of the chemical and physical constitution of the blood and of the nervous and muscular structures, when subjected to the combined influences of heat and crowding in an impure atmosphere; if it be still further true that decomposition, both before and after death, is more rapid than in any other form of disease, and if this decomposition forms the most favorable condition for the rapid multiplication of bacteria and fungi, and other simple organisms; it is reasonable, in the light of the preceding experiments of Davaine and Stricker, to suppose that these organisms may become carriers of the poison, and may constitute an important medium of its dissemination from the original foci.

Magendie has shown by actual experiments on living animals that an excess of alkalinity in the blood, interferes not only with the freedom of the passage of this liquid through the capillary vessels and diminishes the property of coagulation, but also, when thus modified, the blood tends to penetrate the walls of the capillaries by imbibition, and to produce those disorders in the mucous membrane, which have long been known under the name of inflammation.

Magendie by injecting carbonate of soda into the veins of animals, produced edema of the lungs, with its pathognomonic signs at the outset, and cadaveric lesions when it causes death. Thus proving that when the blood becomes surcharged with an alkalin principle its serous matter increases in quantity, escapes from its vessels among the lobular ramifications of the lungs, distends and bursts them, and carrying with it the coagulable part, in a semi-liquid state, collects in irregular masses, which appear to be formed in large measure of fibrinate of soda and potassa.

On comparing the disorders caused by spontaneous excess of alkalinity in the blood, with those produced by injecting carbonate of soda into the veins, or by a frequent repetition of blood-letting, Magendie found the same symptoms and similar results.

If any substance possessing the property of combining chemically and of forming salts with the fibrin, such as fibrinate of soda, potassa, or ammonia, be injected into the veins of a living animal, the fibrin will lose its coagulability, and this change affects the blood generally, and although it may contain the usual proportion of fibrin, it becomes unfit for circulation, and stagnates in the capillaries and especially in the pulmonary vessels, and local lesions, as apoplexy, hemorrhage, or hepatization follow.

Magendie has in like manner, tested the effects of defibrinization upon the process of inflammation during the reparation of wounds. He selected a dog from whom he had successively removed several portions of fibrin. A longitudinal incision was made through the skin, and some depth of muscle in the anterior and middle part of the neck. The blood that escaped from the divided vessels appeared more liquid than usual; it did not coagulate on the blade of the bistoury. The lips of the wound were united by the twisted suture, and the animal left to himself. The animal survived the operation a few days only. An examination of the wound after death revealed the absence of any real adhesion by coagulable lymph, and the divided tissues were discolored, dry and hardly at all swollen.

The older writers were acquainted with the fact that alkalin salts prevented the coagulation of the blood, and John Huxham in his "Essay of Fevers," uses this fact to explain the changes of the blood in scurvy and putrid petechial fevers:

"It is well known that volatile alkali salts mixed with the blood, when just drawn, or rather after it runs from the vein, keep it from coagulating and hinder it from separating into crasamentum and serum, as usual. The experiment is easy, and every one will find it true on trial. This very adequately resembles the blood drawn from the bleeding scorbutics, and also from most persons that labor under putrid petechial fevers, when the blood is drawn very early in the disease.

"All humors of the body, actually putrefied, become a strong alkali, and putrid blood loses its consistency, and soon after its color, running into a yellowish dark-colored sanies. The blood drawn in some greatly putrid petechial fevers, hath had this appearance, and been observed actually to stink as soon as drawn, as well as the urine, as soon as made; so far was the putrefaction advanced, while even life was still subsiding. The surprisingly great and speedy corruption of bodies dying of pestilential fevers with spots, shows this likewise; I have known such a corpse air as much, as they call it, in seven or eight hours, as dead bodies commonly do in seven or eight days, and to leak out a most putrid sanies, from all the outlets of the body; which by-the-by, is a reason why persons dying of such fevers should be buried very soon."—"An Essay on Fevers," etc., by John Huxham, M.D., 1757, pp. 50, 51.

Andral has shown that in the diminution of the fibrin, relatively to the globules, we must recognize the grand condition of the blood favorable to the production of hemorrhages; and in his investigations he found the relations of these two factors so constant that he found it impossible not to regard the one as the cause of the other. In scurvy the proportion of globules is natural, or varies within narrow limits, while the quantity of the fibrin is diminished, and its coagulative quality is at the same time altered; and this condition is most favorable to the production of repeated and profuse hemorrhages.

The tendency of the formation of petechial and

livid spots, during the progress of malignant fevers, in the Middle Ages, is referable chiefly to the scorbutic condition of most patients, at those times, when salt meat constituted the chief nutriment during a large portion of the year, and fresh vegetables were almost unknown. In this connection it should be remembered, that authors have declared that they have found an excess of alkaline matters in the imperfectly coagulated blood of persons who have died of low fevers or scurvy, attended with livid petechiæ and spots. An analogous result was announced by M. Frémy and Andral.

Without doubt the supposition is correct that the peculiar hygienic condition of the people of Europe, before the eighteenth century, caused them to be frequently attacked with diseases, one of whose principal elements, if not their starting point, was a state of dissolution of the blood. The dissolved and incoagulable blood, petechial and passive hemorrhages, so constantly described by authors, in their histories of epidemic fevers, in the Middle Ages, are most philosophically referred in a measure at least, to the scorbutic state of the blood of the patients, and to the bad ventilation and filthy habits of the times. In the epidemics which prevailed in Europe during the Middle Ages, it was common to observe gangrene, hemorrhage from various parts, extensive ecchymosis, or thousands of petechiæ covering the skin, while the symptoms of typhoid fever, and of the various contagious eruptive fevers, developed themselves with a high degree of intensity, and the greatest rapidity. These affections were the external manifestation of an internal condition of the blood.

Erasmus, the philosopher, who flourished toward the close of the sixteenth century, wrote that in his day, the inhabitants of London, were every year, from spring to harvest, attacked by a malignant fever, which committed the greatest ravages in that city, and especially among the poorer classes. "The supply of water," Erasmus says; "fails the inhabitants; they have to seek it at a great distance from the city; the river water is carried on their backs, and is so dear that the poor can not procure enough of it to wash themselves, and keep their houses clean. These houses are of wood, and very cold in winter, which makes it necessary to fill the rooms with straw. But as this can not be often renewed, it becomes spoiled and very injurious."

Grant who practiced medicine, and wrote toward the close of the last century, suggested the inquiry, whether the peculiar hygienic condition of the people of Europe before the eighteenth century, must not have caused them to be frequently attacked with diseases, one of whose principal elements, if not their starting point, was a state of dissolution of the blood. It is certainly remarkable that the observers of preceding ages, constantly speak of dissolved and incoagulable blood in their histories of epidemics.

Huxham in his "Essay on Fevers," has given a large number of observations, illustrating the great tendency to petechiæ and passive hemorrhages in the fevers of those times.

Andral in treating of the changes of the blood in scurvy, records the disappearance of this disease, and of the great febrile epidemics of the Middle Ages, and says:

"We must therefore admit, that in consequence of the change in the nature of the influences which necessarily act upon men, the blood which receives before the solids the

impression of the greater part of these influences, must present changes in its constitution proportioned to those undergone by the agents which operate upon it. It would appear then, that there must have been a time, when a very peculiar constitution of the blood engendered maladies, which in certain respects, may have differed from those now observed, and may not have required the same treatment. And thus it is that at different periods of the existence of our race, and the diversity of influences to which it may be subjected, diseases of very different types may arise, and undergo changes in their essential nature, which are revealed to us by the specific character of their symptoms."

The changes of the blood in certain cases of yellow fever, may have been the *result* and not the *cause* of the aberrated nervous actions. If this be true, the petechiæ and spots, observed in a certain proportion of cases, should not be regarded as true cutaneous affections characteristic of the exanthemata.

It has been said that extreme agitation of the nervous system may deprive the blood of its power to coagulate. According to several observers, a similar effect may be produced by a strong moral emotion, a concussion of the brain, the destruction of a certain portion of the spinal marrow or a violent blow upon the pit of the stomach, affecting the nervous plexus of that region. If facts of this class were appropriately verified, they would doubtless be of the highest importance; for they would show that the nervous system exerts a powerful influence over the constitution of the blood, and that consequently a lesion of innervation may deteriorate the blood, just as an alteration of the blood may modify the nervous action. Professor Dupuy announced that by dividing the pneumogastric nerves in horses, the blood of these animals lost its property of coagulating; Dr. Mayer, on the other hand, having tied the pneumogastric nerves in living animals, found that uniformly the blood had coagulated throughout the entire pulmonary circulation. These facts, as well as those relating to the effects of lightning, excessive heat and excessive exercise in warm weather, require additional proof. If it be true that the changes of the blood may be in accordance with the portion of the nervous system affected, as in section of the pneumogastric and sympathetic, it may be inferred that the changes of the blood in yellow fever may vary within certain limits with the portion of the nervous system chiefly involved.

#### EXPERIMENTS ON THE EFFECTS OF PUTRID ANIMAL MATTERS.

One of the most remarkable phenomenon presented by animals into whose veins Magendie more than thirty years ago, injected putrid substances was what is termed inflammation of the intestines; that is to say, exhalation of a matter having the color of washings of flesh.

Various observers have pointed out the effects of certain animal substances in raising the temperature when injected into the circulation. Billroth and Hufschmidt, found that in all the cases in which putrid solutions or recent pus were injected into the subcutaneous tissue or into the blood, there was a rise of temperature in the rectum, which was considerable even within two hours after the injection, and reached its maximum in from two to twenty-eight hours; that the minimum exceeded the normal temperature by 1.6 C. (2.88 F.), and the maximum, 2.2 C., (3.96 F.), and that if the injection was only done once, a rapid defervescence generally

set in, shortly after the acme had been reached; while on the other hand, after repeated injections death constantly occurred, generally with very high temperatures.

C. Weber has determined by similar experiments, the heat producing and inflammatory effects of pus, of fluids from inflamed tissues, and of pyemic and septicemic blood, and even of the blood of an animal merely suffering from simple inflammatory fever, when injected subcutaneously or into serous cavities.

Frese by numerous experiments, showed that the blood of animals suffering from any kind of fever, induced a rise of temperature, when introduced into the circulation of a healthy animal of the same species.

(To be continued.)

## PRE-COLUMBIAN LEPROSY.

BY ALBERT S. ASHMEAD, M.D.

LATE FOREIGN MEDICAL DIRECTOR, TOKIO HOSPITAL, JAPAN.  
NEW YORK.

(Continued from page 672.)

Professor Putnam, of Peabody Museum, Cambridge, Mass., with whom I discussed this subject at some length, is not of opinion that a horror of leprosy in ancient Peru would stand in the way of the burial of leprous representations with their dead. "For," says he, "whatever custom has been transmitted from generations to generations is, in Peru, always kept up, whatever might have been the events and circumstances which might deprive the custom of all meaning. Even if they do not understand the meaning of a rite, they will perform it because their fathers did." Mummies are now found in that country, tied up in sacks, the false head sticking out, tied up separately, just as they were in the distant past. The custom was, and is still, to bury with the dead such objects as might indicate his condition of life, or any peculiarity belonging to him as an individual, even some circumstance peculiar to the time in which he lived. There is a mummy in the Peabody Museum which was buried with a decree of the sovereign Pontiff which was published at the time when the man was living, and which, so far as we can see, had nothing to do with him as an individual.

Professor Putnam tells of his discovery of a corpse in one of the many stone graves scattered over Tennessee, Arkansas and Missouri, which presented a curvature of the spine, and buried with the same he found a piece of pottery representing that identical curvature. Therefore we may expect, even if only one such is found, that some relation existed between deformities of deceased persons and the objects which were buried with them. In Professor Putnam's museum, he informs me there is a piece of *huacos* pottery, showing the side of the nose and the side of the upper lip and part of the cheek eaten away. The pathologists of Harvard University, who examined this specimen, are of the opinion that these deformities might represent lupus. The same pathologists are not able to affirm that the so-called evidences of syphilis, in ancient bones of America, which are so plentiful in the Peabody Museum, are of any value to prove the disease. They question whether syphilitic disease could produce effects which could not be mistaken for the effects of some other diseases, as tuberculosis, rheumatism, etc. Professor Putnam personally has gone over the same ground as Professor Joseph Jones. The latter thought he had

found unmistakable evidences of pre-Columbian syphilis. Putnam found no evidences of the Tennessee mounds, which he could swear to as being certainly syphilitic.

I called Professor Putnam's attention to a Peruvian skull in the American Museum, of the Bandelier collection, which was being classified. It was an Inca skull, and showed evidence of disease at the junction of the parietal and frontal bones in the supratemporal region; a diseased spot of an inch and a half in diameter. The bone was cancellated and eburnated, with deep corrugations as if eaten by disease; the tissue was almost eaten through. But what was more peculiar was that a knife mark so fine that it could only be seen clearly with a glass, passed around the diseased spot. When held to the light and examined from the inside, through the foramen magnum, this part of the skull appeared almost entirely eaten through. No evidence of disease except by this transmission of light could be observed on the internal surface of the skull. Evidently an operation had been made on a tumor or ulcer of the scalp, and the instrument had left its mark on the bone beneath the periosteum. This looks very much like syphilis.

Professor Putnam showed me a trephined Inca skull which evidently had not been fractured. It was evident in this specimen that a round flap of scalp had been removed before the operation. This evidence consisted in a whitening and a smoother appearance of the bone. Putnam thinks that if this operation was really performed without any fracture to warrant it, it may have been done to release some evil spirit, which their superstition led them to suspect was in the skull. My own opinion is that we have here an exostosis, and one that might well have been syphilitic.

According to Professor Putnam, there are numerous evidences of intercourse between America and Asia in very ancient times. "There were," says he, "probably two routes from India to this country; one through the Malay archipelago and thence from island to island, and slowly through numerous generations, up to the Aleutian Islands, where Behring's Strait alone separated the slow invasion from the great continent." Putnam supposes that when this slow emigration had reached this extreme point, the commercial population of America went to meet them. I may here say that it would be just as probable that the people who could creep from island to island for centuries might have themselves made that last step, and crossing the strait, entered in relation with the population of the continent. The other route is across the South Pacific Islands.

"If leprosy inoculated America before Columbus, it must have occurred," says Professor Putnam, "very early in the history of this continent. It must have long antedated the earliest period at which it could have inoculated Japan, 660 B. C. For the disease must have come with that East Indian current, if there was such current, when it touched South America; and this was certainly long before 660 B. C."

Dr. Augustus Le Plongeon, whose explorations in Yucatan have already been referred to, has kindly given me the following facts about his experiences in Peru and Yucatan, as far as they relate to my subject:

"First as regards Peru. You may not be aware that I have practiced medicine in Lima from 1862 to

NOTE.—If leprosy had come to America from East Asia by this route, we should have some indications of it, by traces left in the South Pacific Islands. But there was never leprosy in those islands.

1870, studying meanwhile ancient Inca civilization. My collection of ceramics, dug up under my supervision from the *huacos*, was one of the most complete in Lima when I left the city. My practice was very extensive among all classes of society and I must say that, at this moment, I do not recall having seen cases of leprosy among the Indians. The cases I recollect having seen were among the negroes particularly and the white descendants of Europeans,<sup>5</sup> that is the Creoles. Of course syphilis was, and is still common among the Indians. Anciently, throughout America, it was for some reason unknown to me, regarded as a "sacred disease." I have not used the Quichua language for so many years that I have wellnigh forgotten it. I do not remember if it contained a word for leprosy. . . . Professor Bandelier, who is now delving in the tombs of the ancient Peruvians has sent some of his finds to the Museum of Natural History in Central Park. Among other things a curious skull, with a deep hollow, caused I should judge by syphilis, and a lot of curious jars, etc. . . . I have never heard that those affected with leprosy in Peru were kept apart from other people. I suppose that the cases were too few to attract the attention of the authorities. As to Yucatan, where I have resided during eleven years, mostly among the aborigines, I do not recollect having met with a single leprosy case among them. There were a few cases of syphilis, where they have had contact with the whites. To-day the Indian population of Yucatan seems to be a particularly healthy vigorous race. I have seen cases of leprosy, but they were confined to the Creoles. Two of the principal families of Merida, the capital, are known to be leprosy. Juan Peon Contreras, a member of said families who generally intermarry among themselves, although very wealthy, was at one time director of the Yucatan Museum, and a disgusting object to look at, literally falling to pieces. Still he was commingling with other people without hindrance. Another such case I saw at the Island of Cozumel. I repeat, the cases are rare. I have no doubt that the disease was known in the country ages before the advent of the Spaniards. The Maya word for leprosy is *naycan*, from the verb *nay*, to corrode, to eat up. This is not a name of modern invention; it is found in the dictionaries and vocabularies of the language made by the Franciscans in the sixteenth century. I have a small medical book written in Maya language by a native, one hundred years ago, but I do not find in it any mention of leprosy.

"My study of the mural paintings in the funeral chamber of Prince Coh, at Chichen, also of the bas-reliefs that adorn the walls of the public monuments in that ancient city, proves to me that in remote ages the inhabitants of Yucatan, in fact of all Central America, had as close communication with those of all other civilized countries as they have to-day. They had close relations with India and Indo-China, where they introduced their civilization, as I show in my book 'Queen Moo and the Egyptian Sphinx,' that will be given publicity in two or three months. I discovered portraits of Carthagenians sculptured on the walls; representations of negroes from Africa, Mongolians from East Asia, Burmese from Indo-China, etc., painted and carved on pillars and walls. In fact the Nagas, the serpent worshippers, who developed such high civilization in the

south of India and the Indian peninsula were immigrants from *Pátala* (America), who reached Asia in times anterior to the invasion of India by the Aryans.

"I do not suppose that sailors in those times were more careful than sailors in our days, and I have no doubt that they spread diseases among the inhabitants of the countries they visited, just as the crews of Captain Cook spread syphilis among those of the islands in the Pacific. The communication between Asia and America being then frequent there can be no doubt that such contagious diseases as syphilis and leprosy were disseminated throughout the earth's inhabitants as they are to-day, and it seems to me impossible to determine where such a peculiar disease originated. We know that at one time syphilis was as common in America, as leprosy in East India, and it is most probable that the inhabitants of these countries interchanged compliments; those of America introducing syphilis into Asia, those of Asia importing leprosy in America."

Diego de Landa, in a manuscript written in 1566 and entitled "*Relacion de las Cosas de Yucatan*," in a chapter entitled, "*Varias Calamidades experimentadas en Yucatan en el siglo anterior á la conquista, huracanes, pestilencias guerras*, etc." says, that "those who escaped took heart of grace to build houses, and cultivated the land, and multiplied themselves, being much aided by fifteen years of good and healthy weather, and that the last year was the most fertile of all; as they began to reap their harvest there broke out in the whole country some pestilential fevers, which lasted twenty-four hours. After these diseases abated, there came a stream of gnats. From this pestilence many people died, and a great part of the harvest remained ungathered. These miseries were succeeded by a pestilence of large pimples which rotted the body with great stench, so that their limbs fell off in four or five days."

This is the only passage of the "*Relacion*" which mentions anything having the least resemblance to leprosy. There is falling off of the limbs, but they fall off in four or five days, and it is almost evident that the rottenness belonged to the soft tissues, and not to the bone. It may have been smallpox.

In Cogolludo's "*Historia de Yucatan*" (Diego Lopez Cogolludo, Madrid, 1688) where he gives a description of all the calamities, diseases especially, which afflicted the peninsula, there is not one line that can be interpreted as a reference to leprosy.

NOTE.—*Milagrosa, que no fe, sabe su origen, etc.* Miracles of all kinds due to an image of the Holy Mother. Cures an apostema on the sole of the foot, a tumor in the face, and in the throat. Fevers of every description cured. Sick stomachs cured by the Holy Image, etc.—(Lib. xii, Cap. xix.)

*De otros milagros.*—An Indian woman, having given birth to a child, could not for a whole hour eject the natural superfluity, etc. Another feels sudden pains in the stomach, etc. Another woman feels a pain in the temples, which extends presently to the whole face; Holy Image brought, and patient cured. Fever of a youth cured. Other fever. During five months a boy 14 years old had had fever, and after a while his face and his legs swelled. Cured.—(Lib. xii, Cap. xx.)

The conquerors and original colonists seeing the continual sufferings from diseases, of the poor, strangers as well as aborigines, founded a hospital, which has now existed for eighty years and more, at the date of this writing. How they founded it, the King being patron, how it was administered at the expense of the city and intrusted to the monks of St. Juan de Dios, is stated in this book, etc.—(Lib. i, Cap. xiv, p. 216.)

Death of Landa. The time came which the Divine Majesty

<sup>5</sup> They suffered from elephantiasis.

had appointed for giving to the blessed Bishop Don Fr. Diego de Landa, the reward which his many services and virtues merited; he died in consequence of a bad cold which he took while preaching on the passion and death of Christ. He became feverish, and felt a puncture in the side. He sent for counsel to our hospital and our physician considering the pain accompanying the fever, judged that it was a pain of the side and bled him. The Bishop said at once that he believed himself to be dying and prepared for his last hour. Lot of absurd details.—(Lib. vi, Cap. xviii.)

*Enfermedad peligrosa en Merida, año de 1609, etc.*—In that same year 1609, in the month of September, the inhabitants of Merida were much troubled by a disease; the Spaniards had had little experience of it in this country, and it was very dangerous. It consisted in hot fever with measles and pustules. Processions resorted to. At the end of that year the disease passed away.—(Lib. ix, Cap. i.)

*Don Gaspar Nunez de Leon mourat de melarchia*, a word which is not in the dictionary, and has some relation with honey.—(Lib. xii, Cap. i.)

*Milagro Notabilissime con unos Indios, etc.* The miracles with Indians is this, in two words: they were deeply buried while digging, and by the intercession of San Diego, dug out again. (No leprosy.) Divers other accidents are reported. There was also a dying priest whom prayers recalled to life.—(Lib. xii, Cap. x, p. 709.)

*Desgracias procedentes a la peste, etc.* A number of ships taken and burned at sea. In June the pestilence began in Campeche, and soon the city was said to be entirely deserted. Orations, processions, etc. At the end of July the disease began in Merida, where many persons perished in a few days. (No leprosy.)—(Lib. xii, Cap. xii.)

*Varios accidentes con que morian los enfermos, etc.* Symptoms—Various accidents. Terrible headache and pains in all the bones, which seemed to go to pieces, or to be pressed as in a vise. After a short time violent fever sometimes, but not always with delirium. *Vomissements de sang corrompu*, and after this symptom few recovered; others had a flux of the belly, of choleraic humors. (Yellow fever?)—(Lib. xii, Cap. xiv.)

*De algunos senalados religiosos que, etc.* Some distinguished ecclesiastics who died of the pestilence. One mounts into the pulpit all right, and comes down with the symptoms of pestilence. Dies the eighth day. Another is infected while taking care of the sick. Other cases of the same kind. (Yellow fever?)—(Lib. xii, Cap. xv.)

(To be continued.)

## SOCIETY PROCEEDINGS.

### National Association of Railway Surgeons.

*Abstract of the Proceedings of the Eighth Annual Meeting, held in Chicago, Ill., May 1, 2 and 3, 1895.*

#### FIRST DAY—MORNING SESSION.

The Association convened in the hall of the Young Men's Christian Association, and was called together by the Chairman of the Committee of Arrangements, Dr. A. I. Bouffleur, of Chicago.

Prayer was offered by Rev. Dr. Thomas.

Dr. BOUFFLEUR introduced Hon. A. F. Walker, of Chicago, who delivered an "Address of Welcome." Dr. W. B. Outten, of St. Louis, responded on behalf of the Association.

PRESIDENT THORN was then introduced by Dr. Bouffleur, and delivered the

#### PRESIDENTIAL ADDRESS,

In which he reviewed the foundation and growth of the Association, which in 1888 had 181 members, and now has over 1800. A tender tribute was paid to the late Dr. A. W. Ridenour, of Massillon, Ohio, the inspirer and progenitor of the Association.

The reports of the Secretary and Treasurer were then read, and on motion, adopted.

Dr. WOOSTER, of Grand Rapids, Mich., offered a resolution pledging support to *The Railway Surgeon*.

On motion, the Association adjourned till 2 P.M.

#### FIRST DAY—AFTERNOON SESSION.

After some routine business was transacted, the reading of papers was proceeded with.

Dr. J. B. MURDOCH, of Pittsburg, Pa., read a paper entitled AMPUTATIONS CONSECUTIVE TO TRAUMATISMS.

In brief, Dr. Murdoch said: Amputations are performed consecutive to traumatism for the following reasons:

1. To save life, because of the fact that nature, unassisted, would succumb before the patient could recover from the injury; and 2, because the limb has been so destroyed by the injury that nature, even when assisted, is unable to restore it sufficiently so as to be useful to its possessor.

When should amputation be performed? The answer to this question is plain. If the amputation is inevitable it should be done at the time when it can be done with the least risk to life.

In coming to a conclusion whether we shall amputate or not, we must consider the age of the patient, his habits, the condition of his health, his environment, and the care he will receive while under treatment. We must also consider whether, in case the limb can be restored, it will be more useful and less painful than a mechanical appliance. When the surgeon is in doubt he should give the patient the benefit of it and withhold the knife.

A spirited discussion followed this paper, in which Drs. Thos. H. Manley, W. P. King, Emory Lanphear, W. B. Outten, E. W. Lee, P. H. Hoy and J. L. Eddy participated.

Dr. JOHN E. SYLVESTER, of McArthur, Ohio, narrated an interesting case of bloodless amputation at the hip joint, the patient being a 16-year old boy who took 164 grains of morphia in twenty-four hours, and is to-day alive and well.

Dr. W. H. BUECHNER, of Cleveland, Ohio, contributed a paper on "Pirogoff's Amputation," strongly favoring it.

"Silicate of Soda in Surgical Dressings," was the subject discussed by Dr. S. R. Wooster, of Grand Rapids, Mich., in which he highly recommended it in preference to other material.

A paper by Dr. Thomas H. Manley, of New York, was read by title, at the request of the author. It was entitled "Traumatic Arthroses."

The Association, on motion, then adjourned till 9 A.M., Thursday.

#### SECOND DAY—MORNING SESSION.

Dr. B. MERRILL RICKETTS, of Cincinnati, Ohio, read a paper entitled

#### EMERGENCY SURGERY IN THE ABDOMINAL CAVITY.

Pain is not always indicative of a large amount of exudation.

The presence of a large amount of fluid is not always accompanied by a rise in temperature.

There is no means of determining the character of the fluid without exploration.

The use of an exploring needle is the only means of positively determining the presence of fluid.

The temperature is sometimes subnormal.

The fluid should not be allowed to reach above normal in quantity.

It should be removed as often as necessary to keep it within the normal amount.

Open drainage should be made in all cases of tubercular fluid, even though it be within the spinal canal, by means of the lumbar puncture.

Surgical anesthesia is not necessary in case of cerebral meningitis.

The probabilities are that the irrigation of serous cavities by some pus destroyer may aid much in effecting a permanent cure.

Narcotics in any form are contra-indicated; absorption is less likely to occur with than without them.

Antithecine may prove itself one of the most valuable means in treating tubercular serous cavities without mixed infection.

HON. R. C. BELL, of Fort Wayne, Ind., was then introduced, and addressed the Association on the subject of

#### AN EXPERT WITNESS.

In beginning his address Mr. Bell said:

I am not presumptuous enough to think for a moment that I can instruct you in any of your duties as expert witnesses. Railway surgeons are very frequently called to the stand to testify, growing out of their employment by railroads. It must be so, and railways must employ surgeons. There are several reasons, a few of which I will mention. First, it is the requirement and dictate of humanity. As long as railways are operated, as long as we are to fly, as it were, upon wings from one side of the continent to the other, day and night, accidents will occur. Human suffering follows and that suffering must be alleviated by the best means that are attainable.

When you are called to the stand as expert witnesses you are placed in an exceedingly delicate position. You are known to be in the employment of a railway company, and

they ignore too often the fact that you are not employed as witnesses. You have been employed for other services. But you are required to give your opinion upon subjects in a manner which may militate for or against the respective litigants. I wish to add my testimony to the fact that after an experience of a quarter of a century I can not recall a single instance when the honest judgment and opinion of its railway surgeon has swerved a hair's breadth because of his employment by a railway company. I was witness as a lawyer to the fact of the elevation of the standard of experts and their testimony by the system of medical ethics that has been adopted and become general throughout our country. Railway surgeons because of their employment are not expected to become claim adjusters or detectives for railway companies. And nothing can be more embarrassing to a railway attorney in trying a case than to find the attending railway surgeon has made himself a partisan on the company's side.

Let me give you a little pointer. Don't know too much. It is the way to avoid a good deal of trouble on the witness stand. A man can tell what he knows, but, in the language of the old schoolmaster, "It is exceedingly difficult for an individual to communicate to others that which he does not himself possess."

DR. MILTON JAY, of Chicago, followed with a paper entitled "Thoracic and Pulmonary Injuries."

DR. ARTHUR D. BEVAN, of Chicago, read a paper entitled REAL AND ALLEGED INJURIES OF THE SPINE, which was freely discussed. The more important points made by Dr. Bevan were:

The subject of injuries of the spine has received in the last thirty years more attention from medico-legal experts than possibly any other subject.

Real injuries of the spine present positive and immediate symptoms.

Alleged injuries of the spinal cord without positive and immediate evidence of gross lesion are either cases of malingering or abnormal cerebral conditions, psychoses, or a combination of the two.

These psychoses are the results of two factors: first, a brain readily affected by suggestion; or, second, suggestions furnished by an accident with or without injury to the individual, or by suggestions furnished by the hope of pecuniary gain; and lastly, and of greater importance, suggestions furnished by medical attendants.

These cases all recover when the exciting causes are removed, rapidly under proper surroundings and advice, but recovery may be indefinitely postponed by improper surroundings and improper advice.

These psychoses will not receive their proper medico-legal position until the medical profession has been generally educated in the subject, and until legal means are provided for the punishment of malingerers and their alleged medico-legal experts.

In the afternoon the Association attended a surgical clinic given by Dr. N. Senn in the upper amphitheater of Rush Medical College. Dr. Senn showed several cases upon which he had previously operated, and also operated on several.

#### THIRD DAY—MORNING SESSION.

DR. W. B. OUTTEN, of St. Louis, read the report of the Committee on Necrology, which, on motion, was referred for publication.

The election of officers was proceeded with, the result being as follows:

President—Dr. J. B. Murphy, of Chicago.  
 Secretary—Dr. D. Emmet Welch, of Grand Rapids, Mich.  
 Treasurer—Dr. E. R. Lewis, Kansas City, Mo.  
 Vice-Presidents—Drs. W. B. Rogers, of Memphis; A. D. Bevan, Chicago; E. F. Beasley, Lafayette, Ind.; H. Logan, The Dells, Ore.; Geo. Graves, Herkimer, N. Y.; P. F. Vassering, St. Louis, Mo.; A. C. Scott, Temple, Texas.  
 Executive Committee—Drs. S. S. Thorn, Toledo, Ohio; J. A. Barr, McKee's Rock, Pa.; A. I. Bouffleur, Chicago.  
 Assistant Secretary—Dr. S. P. Wooster, Grand Rapids, Mich.

Chairman Committee of Arrangements—Dr. B. M. Ricketts, of Cincinnati, Ohio.

Chairman of Committee on Transportation—Dr. W. B. Outten, of St. Louis, Mo.

Place of next meeting—Cincinnati, Ohio.

Following the election of officers, the reading of papers was again taken up.

DR. W. R. HAMILTON, of Pittsburg, read a paper entitled "Syme's Amputation."

DR. C. D. WESCOTT, of Chicago, read a paper entitled

#### THE EYE IN RAILWAY SURGERY.

He said: An injury to the eye is the most common accident in the whole list. Hot cinders and molten metal frequently burn quite deeply into the conjunctiva. After they have been removed under cocain and thoroughly cleaned with a bland antiseptic, a small quantity of sterilized vaselin or olive oil dropped into the eye is very soothing and grateful. It is usually best not to bandage an eye thus injured, but the lid should be frequently bathed with warm borax water and the eye flushed with a saturated solution of boracic acid every three hours. Cocain should not be prescribed as an anodyne. Iced compresses will usually relieve the pain if so applied when the pain is continuous. In our shops and factories all over the world employes are daily jabbing at the cornea with sharpened sticks, pocket knives, horseshoe nails, and other improvised instruments, in attempting to remove pieces of stone, steel, emery, etc., which are innocent as compared with the instruments and methods employed. If these offending particles are not deeply imbedded in the cornea they may usually be removed without the slightest trouble by simply wiping them away with a little swab made by twisting some cotton on the end of a toothpick or something like it.

#### IS THERE ANY SPECIAL FORM OF DISEASE PECULIAR TO THE RAILWAY SERVICE?

This paper was read by DR. OUTTEN, of St. Louis. His remarks were founded on the cases occurring in the past eight years among the employes of the Missouri Pacific Railway system. Dr. Outten said in substance: It may be a surprising fact to some that the most sickness comparatively, exists among the section hands, and the next highest is the clerical force. A compilation shows the proportion of illness in different occupations as follows: Section men, 28,687; clerks, 16,269; engineers, 6,369; firemen, 8,024; brakemen, 11,390. In proportion to their number the most healthy classes are the engineers and brakemen. An analysis of 170,570 cases treated in the hospitals of the Missouri Pacific system shows that 64 per cent. of the total number of cases were rectal diseases. This certainly proves that rectal disease is peculiar to the railway service and due to the enforced irregular habits of railway employes. Other statistics gleaned from the reports show diseases ranking next highest are malarial fever, rheumatism, lumbago, diseases of the respiratory and digestive organs, and nervous diseases. I want to especially mention the fact that in over 170,000 cases among our employes, only thirty-five were to be classed under the head of alcoholism.

#### DR. J. A. BARR, of McKees Rock, Pa., read a paper entitled THE CARE OF THE INJURED FROM THE PLACE WHERE INJURED TO THE HOME OR THE HOSPITAL.

He said: The first step in the care of the injured should be taken by the railway company in the providing every engine with a box containing a rubber compress, absorbent cotton, bandages, etc., with instructions how to use in case of accident until the surgeon arrives; with caution against the too free use of stimulants in the shape of whiskies, wines and brandies, for we have seen much harm result from their use by persons not knowing the true nature of the injury; also caution against the use of dirty waste, dirty handkerchiefs, black oil and other lubricants being applied to the wounds; for we take it that every railroad injury, from the very nature of the case, is septic, and these things only add fuel to the fire. The surgeon should keep on hand at all times an emergency bag containing anesthetics, antiseptic dressings, bandages, tourniquet, stimulants, and instruments for all emergencies. When an injured person is liable to be some time in transit, the wound should be thoroughly cleansed by washing it in hot water, carbolyzed water, or better still, a solution of antipyrin. For the relief of pain, morphin, administered hypodermically, and cocain, applied locally, are the best remedies. When there is shock get the patient away from the crowd, cover him with blankets, and use in addition hot water bottles, hot irons or anything else that can be had, placing them under the body, but taking care not to burn an unconscious patient. Then give stimulants of alcohol in small, oft-repeated doses. In cases of severe burns or scalds apply common baking powder, mixed with water to the consistency of cream to the burnt surface. Another very good thing is simple petroleum spread thickly on cotton, cotton batten or old linen and applied to the surface. To transport a patient place him on a cushion, cover him with clothing or anything to keep him warm, place him on the floor of the car with the head toward the front end of the train, guard against draughts of air, and observe the caution against the too free use of stimulants.

HON. CLARK BELL, of New York, spoke briefly on the topic PERSONAL EXAMINATION OF PLAINTIFF IN PERSONAL INJURY CASES.

He stated that after a long legal strife it was now the law in all States that a plaintiff in a suit for damages for personal injury must submit to an order of the court to a personal examination by experts as to the real nature and extent of the injuries. He urged the Association to labor for the adoption of similar laws in every State, the law to contain provisions in cases where the plaintiff is a woman.

COLOR PERCEPTION IN RAILWAY EMPLOYEES—DO THE ACCEPTED METHODS OF TESTING MEET THE REQUIREMENTS?

Was the subject discussed by DR. LE ROY DIBBLE, of Kansas City. He said: Gross injustice has been done many faithful employees by Holmgran's tests. I think we should pay more attention to a man's mental acuteness than to the acuteness of his vision and color sense, or the cast-iron rules laid down for our guidance. I do not believe it is the intention of the managers of our roads to do any man injustice, but the oculists employed should be men of wide experience, and if they find a man deficient in color sense and yet by actual practical test, he can overcome this defect, he should be retained. It is impossible to measure one man's capacity by another's, mentally or physically. Our rules smack too much of trades-unionism, *i. e.*, measuring every man's capacity not by the highest standards but by the lowest, a common dead level of mediocrity. They should not be like a chain, just as strong as the weakest link, but be put on the basis of common sense, experience and mental capacity of the individual.

DR. OUTTEN indorsed the views of DR. DIBBLE.

DR. C. H. WILLIAMS, of Chicago, showed the tests used in examining employes of the Chicago, Burlington & Quincy Railroad.

Some unfinished routine business was then taken up and disposed of quickly, after which the newly elected President, DR. MURPHY, was installed.

Several papers on the program were read by title in the absence of the authors, and owing to lack of time.

It was ordered that no abstract or report of the proceedings should appear in any medical journal except the *Railway Surgeon*, as the doors had not been closed, the JOURNAL takes pleasure in rescuing from oblivion the very excellent papers that otherwise would have been buried in the pages of an exclusive periodical.

On motion, the Association adjourned to hold its next meeting in Cincinnati, Ohio.

### American Electro-Therapeutic Association.

Fourth Annual Meeting held in New York Academy of Medicine, New York, Sept. 25, 26, and 27, 1894.

WILLIAM J. HERDMAN, M.D., President.

(Continued from page 682.)

MONSIEUR GAUTIER'S paper was read by DR. A. LAPHORN SMITH.

### ELECTROLYSIS IN URETHRAL STRICTURE—A NEW ELECTRODE.

BY GEORGE GAUTIER, M.D., PARIS, FRANCE.

Rigid electrodes with long and thread-like conductor are generally difficult to handle and dangerous for reaching urethral strictures. They get spoiled at each application and are very expensive. For a year past I have employed a new instrument that will supplant them with advantage in all cases and which is easy and harmless to apply. This instrument is composed of a urethral bougie made of gum, the diameter of which varies with the cases to be treated, because we can have them made of all shapes in order to treat accessible strictures; those of the esophagus, urethra, lacrymal canal or rectum. This bougie is cut off at 6 centimeters from its conical end and a platinum tip is screwed on to it  $1\frac{1}{2}$  centimeters in length and of the same diameter as the bougie. This metal end is connected with the negative pole of the battery by a flexible wire which is fixed in the bougie during its manufacture. The introduction of the electrode is easy and made without violence or pain; it follows all the curves of the canal, does not irritate, and permits us to make a slow gradual dilatation which by degrees changes and modifies the nutrition of the parts and surely saves the patient from false passages, retention, and ruptures of the urethra.

The mode of operating: 1, find out beforehand with the

measuring bougie the situation of the stricture, its nature and especially its caliber; 2, inject into the bladder half a pint or more of boracic acid solution; 3, make use of an electrode of the same diameter as the exploring bougie.

Duration, intensity and nature of the operation. The electrode is connected with the negative pole of the battery, the positive pole being attached to a belt 18 centimeters long by 12 wide, covered with amedo or chamois skin, and which is applied to the abdomen or thigh. At the moment when the metallic end of the bougie reaches the strictured part of the urethra we turn on the current until 10, 15 or 20 milliamperes at the most are reached. At this moment we push in the instrument without any violence until it reaches the bladder. If the stricture is long and hard, it requires ten minutes or a quarter of an hour with an intensity of 12 or 15 milliamperes. If the strictures are short and are of unequal dimensions it will be necessary first to treat the longest strictures and to put off for a week the treatment of the other ones. Before withdrawing the electrode we turn off the current and the patient empties his bladder, thus securing the antisepsis of the latter. It is not advisable to employ too large a bougie at first, but the next day and each day following to introduce a catheter, which will also serve to fill the bladder with boracic acid solution.

A second and even a third electrolytic application will be necessary if the strictures are near together and numerous, because with the electrode the dilatation is gradual. We should always allow an interval of ten days to elapse between each application.

Results: I have by this means treated six urethral strictures; the results were in the six cases excellent. I did not notice any complication. I can not say that the cures are definite, because they are of too recent date, but I recommend this proceeding to my brethren, because of its efficacy, its painlessness and harmlessness.

MARGARET A. CLEAVES, M.D., New York City, read the following paper:

### A MEANS OF CONTROLLING AND REGULATING THE STATIC INDUCED CURRENT.

The so-called "static induced," whether developed from a frictional or an influence machine, is a current of an alternating discontinuity, whereby currents of alternating directions commence and cease intermittently.<sup>1</sup>

It is characterized by a series of oscillations, and these may vary, according to the size of the condenser from a minimum of less than 1,600 periods per second (or within the limits of audition) to 1,000,000 or more periods per second.

The therapeutic value of this current is thoroughly recognized, but the difficulty of controlling and regulating it has no doubt militated against its usefulness. In fact the only method of control heretofore in use has been that of separating the discharging rods as slowly and gently as possible. This has effected an adjustment of the frequency, but has not provided for the regulation of the other important factor, namely the quantity or amperage which might be desired with a given number of periods.

When this separation is performed with the greatest care it is still impossible to do away entirely with sudden shocks and jars which are painful to all in varying degrees but especially to nervous sensitive patients.

A certain amount of experimental work in conditions where a profound massage effect was desired, especially in pelvic conditions, convinced me that to obtain its full measure of usefulness and thus to insure its highest therapeutic success, it was necessary to be able to regulate and control the volume or amperage of this current with the same nicety that is possible with the constant, induced or sinusoidal current.

Despite the difficulty encountered in securing this control of the static induced on account of its immense E. M. F., the writer undertook in the early part of 1894 to make some experiments with various patterns of water rheostats, to see if by any possibility a regulator could be constructed on this principle through which this current could be passed without the danger of spark leakage. The first experiments were made with the Bailey water rheostat, and I found that so long as I kept my spark gap as short as the distance between the two milled screw heads, I could perfectly control it.

The same thing was proved with other water rheostats, and the fact established that all that was necessary was to keep conducting material at the maximum sparking distance apart.

Finally, the instrument shown in the cut was constructed for me by the Galvano-Faradic Mfg. Co., of New York City.

<sup>1</sup> Professor Houston.

Inclosed in the glass tube *A* is a cup of pure carbon *B*. This cup is secured at the bottom and forms one of the terminals, the other terminal a tapering carbon rod *C* fastened to a metal rod *D* and wrapped with a sponge at the apex *E*.

On the top of the rheostat connected with a coarse double thread screw (a continuation of the metallic rod *D*) is a metal bar *F*, ending in a large milled screw head *G*. By turning this screw head the carbon point is raised and lowered at will.

The glass is filled with water until it touches the sponge on the end of the carbon rod.

The rheostat is wired on the principle of a shunt circuit and has double binding posts; one to receive the wires from the Leyden jars, the other for the conducting cords distributed to the patient.

The rheostat may be connected directly with the machine in the room in which it is placed, or heavy well insulated wires may be connected with the static induced binding posts and carried through apertures in the wall to an appropriate place at a distance, keeping them at all times the maximum sparking distance apart. It may then be placed at a convenient point for daily use, by the right hand of

one's operating table, for instance, and connections made in that position with the wires from the machine.

It is possible to use it with any size of the Leyden jars and a spark gap of from one to four or five inches. The latter is only desirable with the smallest jars, but with the longer spark gap the current loses the rapidity of its oscillations but gains in E. M. F.

When the rheostat is permanently connected with the machine, as I have indicated, the first thing to do is to arrange the spark gap of the size desired and set the machine in motion, then connect the conducting cords from the rheostat to the electrodes through which the current is delivered to the patient. When all the connections are made for the administration of treatment, the tapering carbon fastened to the metal rod is gradually raised by turning the screw until the current strength desired for the particular application is reached. This can be done to such an extent as to produce the most violent muscular contractions without the patient suffering from any pain, jars or shocks. With appropriate connections every voluntary muscle of the body can be put into a state of activity, with the exception of a few muscles of the head and face, and the temperature raised from a

fraction of a degree to 2 degrees. It accomplishes, in common with the usual administration by means of sparks, a marked nutritional gain. By its use all metabolic processes are encouraged. In vagino-abdominal applications, patients speak of the effect as much more pronounced than from either the induced or sinusoidal currents; an effect which they characterize as a feeling of lightness and buoyancy in the pelvis with an ability to walk with greater ease. It is not well borne in subacute inflammatory conditions of the pelvic organs. Patients with such trouble are prone to have recurrence of pain and soreness, save with the mildest applications.

The current best adapted to the treatment of pelvic conditions where relief from pain is desired as well as relief from congestion, is obtained by using the large or medium jars standardizing the frequency by a very small spark gap, say from one-eighth to one-half of an inch, and gradually turning on the whole available current strength by adjusting the controller. Where profound massage effect is desired, as in prolapsus uteri or relaxed vaginal walls, a longer spark with its greater E. M. F. but with less rapid oscillations is of greater value, and for such uses no other current can take its place. By means of this instrument when once the spark gap is arranged, the machine in motion and the patient in circuit, the operator is able to make any application, general intra-uterine, intra-vaginal, intra-nasal, to the eye or the ear, and so perfectly regulate the current as to make the treatment absolutely painless.

As a result of the physical peculiarities of the static induced, it is impossible to place a resistance in the circuit without damping the oscillations. This damping out effect I can readily appreciate both by ear and touch, but as I am in the habit of increasing the number of revolutions of my machine under these circumstances I am able to compensate for any such loss and maintain sufficiently rapid oscillations, and thus secure the same clinical effect as when there is no rheostat in circuit.

The form of the rheostat is not a new one but an adaptation from a constant current controller already on the market. The features of originality to which the writer lays claim are the conception of the idea of regulating the current strength of the static induced without varying (in any practical degree) the frequency of the oscillations and the peculiar form of rheostat by which that idea is reduced to practice. This rheostat was shown at the New York Electro-Therapeutic Society last April, and has been used by the writer ever since with perfect satisfaction.

68 Madison Avenue.

**The Influence of the Nervous System on Absorption.**—(Leubuscher and Tecklenburg, *Virchow's Archiv*. Bd., cxxxviii, Hft. 2.) The writers publish in brief the results of fresh experiments and of new trials of older ones, which appeared in detail in Tecklenburg's inaugural dissertation, Jena, 1894. These results are as follows:

1. Goltz' opinion, that after destruction of brain and spinal cord the vascular tonicity is increased, so that a frog loses only a few drops of blood from the opened aorta, is insufficient to account for his observation on the loss of blood in the operation.

2. A short time after severing the nerves of one extremity there was seen in that extremity, a dilatation of the vessels, slowing of the blood current and, as a consequence, delayed absorption. This disturbance was compensated after a short time.

3 and 4. If coils of empty intestines are exposed and the corresponding nerves in the mesentery are severed, fluid collects within the coils, pale and clear, alkaline, unaffected by heat, and acting in no way upon albumin or starch. The fluid must therefore be a transudation from the blood, not a secretion from the intestinal mucous membrane. Half as much iodid of potash (in solution) is absorbed from the intestinal coil whose nerve supply is cut off, as from a coil of equal length with full nerve connection. In the jejunum more is absorbed than in the ileum.

5. Dogs in whom the large abdominal ganglia were extirpated, showed after the operation depression, diarrhea, and later, despite feeding, an emaciation, which was overcome slowly, seven to eight weeks after the operation. The urine meanwhile showed an acid reaction, as in starvation of herbivora. Sugar was never found, traces of albumin often, small quantities of blood rarely.—*Centralblatt für innere Medicin*.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MAY 11, 1895.

FOUR "SLUM" CENTERS.

The four American cities—New York, Chicago, Philadelphia and Baltimore—have been made the subject of a voluminous report regarding their "slums," or as DR. ELISHA HARRIS was wont to style them, "les pauvres faubourgs," by the HON. CARROLL D. WRIGHT, Commissioner of Labor. The report is a provisional one and is addressed to the President. The funds set apart for this work amounted to \$20,000 and were wholly inadequate to an exhaustive collection of the facts, so that the centers of the fields, only, were undertaken to be covered.

The report is a book of 620 pages, the larger proportion of which is full of tables conveying finely comminuted tabulated information as to age-periods of inhabitants, nativity and parentage, size of families, illiteracy, occupations and weekly earnings, school attendance, condition of children, condition of married women having specified number of living children, numbers of families and individuals in tenements, the health of people living in the slums, sanitary condition of tenements. About one-seventh part of the total estimated slum population of the four cities, or 582,000 was reached; namely, 83,852 souls are comprised in DR. WRIGHT's report.

The slum population is largely foreign-born; in New York it is more than 62 per cent.; in Chicago it is 57 per cent.; in Philadelphia it is 60 per cent., but in Baltimore it is not above 40 per cent. However, if we look at the total foreign populations of the cities, we find that the foreign-born population of Baltimore is 15.88 per cent.; in the slums it is 40.2; of Chicago 40.98, in the slums 57.51; in New York City 42.23, in her slums 62.58; in Philadelphia 25.75, in her slums 60.4. Of the nationalities tend-

ing to these slums, the Italians predominate in Chicago, New York and Philadelphia, while in Baltimore Germans give the largest percentage; Russians and Polacks come second in Philadelphia and Baltimore. The Irish and Poles are second in New York, while Austro-Hungary and Russia are second in Chicago.

As DR. PORTUGALOFF has expressed his views of rapid up-rising of the land of PETER THE GREAT, when he says: "Not many centuries ago a great desert stretched where now is Russia and where now a-smell as of myriads of pinched bed-bugs is spread all over Eastern Europe," so do Russia and Italy and Poland send to our cities their unclean slum majorities with odorous qualities and difficult sanitary problems.

The percentage of illiteracy is much higher in the slums than in the cities at large, and in all cases the higher percentage of illiterates is among the foreign-born. The range of illiteracy is expressed by 47 per cent. in New York (the highest) and 20 per cent. in Baltimore, where it was the lowest; Philadelphia had 37 and Chicago 47 per cent.

The health of the slum-dwellers was found to be better than was to be expected. This important branch of the inquiry was confided to DR. ALFRED S. HOUGHTON, of New York City. The reports of the experts and agents employed for this inquiry are nearly unanimous in showing small proportional sickness in the slum centers.

It should be stated that the canvass was made in the most thorough manner—just as if a Federal census were in progress—each house and every floor being visited and the inquiry conducted in respect of each person therein dwelling. The schedules show that no more sickness prevailed in the slums than in other parts of the respective cities. While in some of the districts there were found abjectly wretched conditions of the domicile, the small number of cases of sickness was a distinct surprise to the canvassers. The canvass was made in the spring of the year, the windows were everywhere open and the air of the apartments was, far less foul than in the winter season.

Then, too, in all of these cities, the families are too poor to long retain their sick members, if there are hospital accommodations available. In nearly all these cities there are hospitals for general and for specialized diseases, so that if a worthy tenement-house dweller falls sick there is commonly a hospital bed waiting for him somewhere.

O<sub>2</sub> N<sub>2</sub> A<sub>1</sub>.

It is no longer correct to represent the chemie composition of the atmosphere by the familiar symbols O<sub>2</sub> N<sub>2</sub>—argon, the new element, must be taken into the account, and the formula now is O<sub>2</sub> N<sub>2</sub> A<sub>1</sub>.

This era-marking discovery by LORD RAYLEIGH and PROFESSOR RAMSEY, which was fully described in the

JOURNAL of Sept. 1, 1894,<sup>1</sup> is the scientific sensation of the day, and although if the HODGKINS fund prize has been awarded to the discoverers, it has escaped observation, they continue to be the recipients of the highest tokens of recognition by learned bodies everywhere. Among the most recent of these tributes is the award to LORD RAYLEIGH of the FARADAY gold medal by the Chemical Society of London, and of the LEBLANC medal to PROFESSOR RAMSEY by the Société Chimique de Paris; while it is just announced that "on the recommendation of the National Academy of Science the trustees have voted to make the first award of the BARNARD medal for the most important discovery in physical or astronomical science to LORD RAYLEIGH, the discoverer of argon, a constituent of the atmosphere."

In searching for argon in other compounds, PROFESSOR RAMSEY unearthed the fact that an American had barely missed anticipating himself and LORD RAYLEIGH. In Bulletin No. 78 of the U. S. Geological Survey (1892) is a paper by MR. W. F. HILLEBRAND "On the Occurrence of Nitrogen in Uraninite," in which is detailed the process by which the investigator had produced a gas whose properties, as described in the paper, leave little room for doubt that it was argon, in combination, as now known, with helium. From the hints in MR. HILLEBRAND'S paper PROFESSOR RAMSEY selected cleveite, one of the uraninite group, and there found the object of his search. This discovery is of only less interest than that of argon itself, for helium is but little known on account of its supposed rarity.

PROFESSOR BERTHELOT, of the Paris Chemical Society, has also been experimenting with the new gas, and claims to have succeeded where LORD RAYLEIGH has heretofore failed—that is, in effecting a chemical combination of argon. In the course of his experiments to this end, he obtained spectroscopic effects which incline him to believe that the aurora borealis is caused by the action of electric currents on argon and other elements in our atmosphere—hereafter to be indicated by the symbols  $O_2$   $N_2$   $A_1$ .

#### FOR REVENUE ONLY.

The suggestion in the JOURNAL editorial of last week,<sup>1</sup> that the bias of the Report of the Royal Opium Commission was dictated by commercial considerations, receives support from other sources. That exceedingly well-informed journal, the *New York Sun*, says that "East Indian business interests of all kinds must be vastly relieved at the tenor of the British Royal Commission's report on the opium question. That Commission was appointed in the autumn of 1893 to consider the evils of opium eating and the financial difficulties that would be involved should the traffic be abolished by law."

The Commission has found no evils from the "temperate use of opium in India"—on the contrary, such use may be "even beneficial," as it argues from the fact that "the opium habit prevails among some of the most manly, hardworking, thrifty races of India." But the financial difficulties that would be involved, should the half million acres now under poppy cultivation be made unproductive by an adverse report on the use of opium, are very obvious.

The dictum of the Royal Commission will not be accepted by the medical world outside of India, nor even there outside of the native races. As the *Medical Record* says: "So far as Caucasians are concerned we can not too emphatically assert that the Commission's conclusions do not apply at all. The use of opium is a distinct evil. Its moderate use is impossible. There are practically no temperate opium users. The opium eater always wants more and continues to want more until he is physically and mentally a wreck."

The defense of the opium habit by Great Britain is made for revenue only.

#### "CHOLERA AND OYSTERS."

Not content with having fixed the stigma of being a typhoid-fever carrier upon the oyster, our English cousins are now attacking that hitherto supposedly innocuous bivalve as a disseminator of Asiatic cholera. Following the *British Medical Journal's* series of articles on the conveyance of certain water-borne diseases by oysters and other shellfish comes a report by DR. THORNE THORNE to the Local Government Board upon the distribution of cholera in England in 1893, from which it appears that the disease was conveyed to different parts of the Kingdom either by oysters shipped from, or in the persons of excursionists who had eaten oysters in, Grimsby and Cleesthorpe—two popular seaside resorts at the mouth of the Humber.

In its review of the evidence submitted in the report the *Journal* says: "Reverting, in conclusion, to the general question, we would point out that no absolute conclusion is come to in the report, but that portion of it dealing with the question of shellfish and the spread of cholera concludes with words which can not be held to go beyond the inference which may properly be drawn from all the facts set out. They are as follows: 'One thing is certain—oysters and shellfish, both at the mouth of the Humber and at other points along the English coast line, are at times so grown and stored that they must of necessity be periodically bathed in sewage more or less dilute; oysters have more than once appeared to serve as the medium for communicating disease, such as enteric fever, to man; and so long as conditions exist, such as those with which the oyster trade of Cleesthorpe and Grimsby is shown to be associated,

<sup>1</sup> "The Hodgkins Fund Prize," p. 355, vol. XXIII, No. 9.  
<sup>1</sup> "Defense of Opium Eating," p. 685.

—conditions which may at any time involve risk of the fouling of such shellfish with the excreta of persons suffering from diseases of the type of cholera and enteric fever—so long will it be impossible to assert that their use as an article of diet is not concerned in the production of diseases of the class in question.”

Henceforth let the “blue point” be anathema, the oyster be ostracized—anyway until next September.

#### THE COLLECTIVE INVESTIGATION.

In response to many requests, the JOURNAL reproduces in this number the blank form for the collective investigation of the antitoxin treatment of diphtheria, which will be found, as before, following the last page of reading matter. The contributions to this attempt to arrive at a consensus of opinion on a most important and warmly debated question are already so numerous as to give promise of an interesting and weighty set of conclusions, and the promptitude of the responses is no less gratifying—the first filled-out form was received from DR. E. E. FYKE, of Centralia, Ill., 252 miles distant, on Monday morning, April 22, the blank form being first printed in the issue of Saturday, April 20. Not less alert was our San Francisco correspondent, DR. KUHLMAN, whose letter, under date of April 25, appears on another page.

Touching the flat-footed assertions contained in this letter, the JOURNAL will only remark that that which is pronounced “impossible of execution” is being executed. *Ex uno disce omnes.*

PRESIDENT COLE.—As we go to press with a largely increased edition we learn by telegraph of the election of DR. RICHARD BEVERLY COLE, of San Francisco, to the Presidency of the AMERICAN MEDICAL ASSOCIATION. His unfaltering zeal in the cause of science, and his faithful services on behalf of the ASSOCIATION, are well known to the entire profession.

The next annual meeting will be held in Atlanta, Ga., the city of historical reminiscences, noted for its salubrity, its educational advantages and its commercial activity. The members of the ASSOCIATION will have the opportunity of renewing the pleasant acquaintances formed five years ago.

## CORRESPONDENCE.

### Editorial Correspondence.

FORT WAYNE, IND., May 5, 1895.

TO THE JOURNAL:—The JOURNAL Special Train over the Pennsylvania Railroad, left the Union Depot promptly at 3:15 P.M., as advertised. The train was equal in its appointments to all that had been claimed for it by the railroad company. The following are some of those who were on the train:

U. O. B. Wingate and wife, Milwaukee, Wis.  
W. H. Washburn and wife, Milwaukee, Wis.  
H. B. Stehman, Chicago.  
J. T. Priestley and wife, Des Moines, Iowa.  
D. W. Graham, Chicago.

M. E. Connell, Wauwatosa, Wis.  
W. B. Hill, Milwaukee, Wis.  
F. W. Rogers, Hartford, Wis.  
W. Q. Marsh, Sierra Mojada, Mex.  
D. M. Thurston, Beeville, Tex.  
W. Whitford, Chicago.  
Chas. H. Gillespie, Chicago.  
W. C. Abaly, Madison, Wis.  
G. G. Beethooven, C Johnston Smith, Anheuser-Bush Brewing Association.  
H. B. Ellis, Los Angeles, Cal.  
Wm. LeMoyné Wills, Los Angeles, Cal.  
C. F. Greebe, Chicago.  
J. B. Charlton, Clear Lake, Iowa.  
A. C. Wedge and wife, Albert Lea, Minn.  
C. G. Pauly, Iowa.  
E. H. Dorland, Chicago.  
C. Fenger, Chicago.  
U. B. Will and wife, Peoria, Ill.  
N. Senn, Chicago.  
L. H. Montgomery and wife, Chicago.  
E. S. Talbot, Chicago.  
Daniel R. Brower, Chicago.  
T. J. Sullivan and wife, Chicago.  
Albert Sutton, Tacoma, Wash.  
J. W. Graham, Denver, Colo.  
J. B. Murphy, Chicago.  
Joseph Eastman, Indiana.  
W. B. Rogers, Memphis, Tenn.  
W. X. Sudduth, Minneapolis, Minn.  
Marie L. Mergler, Chicago.  
Edward Jackson, Denver, Colo.  
A. C. Corr, Carlinville, Ill.  
W. R. Fringer, Rockford, Ill.  
A. W. Richards.  
John W. Bean and wife, Ellensburg, Wash.  
James W. Cokenower and wife, Des Moines, Iowa.  
R. Beverly Cole, San Francisco.  
J. E. Woodbridge, Youngstown, Ohio.  
A. Garcelon, Lewistown, Me.  
J. B. Hamilton, Chicago.  
R. A. McClelland, Yorkville, Ill.  
M. C. Knight, Aurora, Ill.  
Chas. Truax, Chicago.  
A. J. Horlick, Racine, Wis.  
A. E. Kemick, Chicago.  
M. L. Hildreth, Lyons, Neb.  
H. B. Sears, Beaver Dam, Wis.  
B. C. Whitney, Burlington, Iowa.  
F. E. Sampson, Creston, Iowa.  
Hugh T. Patrick, Chicago.  
Geo. W. King, Helena, Mont.  
J. M. Wick, Cedar Falls, Iowa.  
D. W. Smouse, Des Moines, Iowa.  
D. W. Crouse, Waterloo, Iowa.  
W. R. Skinner, Cedar Rapids, Iowa.  
B. H. Criley, Dallas Center, Iowa.  
F. C. Hull, Carlisle, Iowa.  
H. P. Newman and wife, Chicago.  
E. F. Ingals, Chicago.  
F. B. Turck, Chicago.  
W. J. Bridgman and wife.  
M. B. Ward, Topeka, Kan.  
Elmer Lee, Chicago.  
C. E. Fawcett, Stewartville, Minn.

Jas. A. Lydston, Chicago.  
G. W. Reynolds, Chicago.  
F. J. Maxwell, Keokuk, Iowa.

### His Ipse Dixit.

SAN FRANCISCO, CAL., April 25, 1895.

To the Editor:—As a member of the AMERICAN MEDICAL ASSOCIATION, I ask you to give space in the JOURNAL for the following:

1. The JOURNAL's scheme for ascertaining the therapeutic value of so-called “antitoxin diphtheria serum” is impossible of execution for the following reasons: *a*, it is impossible to identify the so-called Löffler bacillus diphthericus by any description now extant; *b*, it will require at least one year to complete the cycle of a scientific bacteriologic diagnosis of any case of diphtheria—admitting that the disease may be due to a bacillus capable of identification, which has not been done thus far; *c*, statistics unsupported by a scientific bacteriologic diagnosis, including post-mortem examination, are unreliable, inasmuch as the serum-therapy is based entirely upon the factum that diphtheria is caused by the so-called Löffler bacillus diphthericus.

2. In a paper read by me on the 16th inst., before the State Medical Society of California, entitled, “The Status Presens of Antitoxic Blood-Serum,” I have shown by an abundance of scientific data and statistics: *a*, that antitoxin blood-serum antedates Behring as a therapeutic agent; *b*, that the so-called Löffler bacillus is not the cause of true Bretenneau diphtheria; *c*, that antitoxin blood-serums bear no relation to the causes operating in infectious diseases; *d*, that it does not insure immunity; *e*, that it does not cure; *f*, that it causes chemic decomposition of the blood and is a dangerous remedy; *g*, that it increased the mortality in diphtheria in Berlin during the year 1894 about 25 per cent.

Respectfully submitted,

CHAS. G. KUHLMAN, M.D.

935 Market Street.

## BOOK NOTICES.

The History of the Pennsylvania Hospital 1751-1895. By THOMAS G. MORTON, M.D., assisted by FRANK WOODBURY, M.D. 4 to., cl., gilt top, uncut edges, pp. 574. Philadelphia: Times Printing House. 1895.

The late President Hays, in one of his innumerable addresses, pointed out the necessity of compiling county, mu-

nicipal and special histories now, while in the greater part of the country, there were living persons who knew the beginning; that in a few years owing to the restless and migratory habits of the people, even the traditions of the first planting would be absent. History can not be written by contemporaries; it must be written by those living outside and beyond the influence of the personal animosity or friendship which formed the motive for the recorded deed, and these local "histories" commended by President Hays, afford the best possible data for the after-coming historian.

Fortunately, the history of the Pennsylvania Hospital rests on documentary evidence, and we have it here, spread before us in the highest style of art of the photographer and lithographer; an art by which the old documents are preserved, yellow with the century and a half that has passed over them, and wrinkled as they appear in this year of our Lord 1895. Pictures of the old worthies as they appeared in their day are republished, among others a half tone from the identical engraving from which was taken the picture of Benj. Rush that we reproduced last week. It is true that Americans have no old ruined castles to point out to the visitor, but we can do better; we may point to some of our great charitable institutions, after a century and a half of usefulness not only showing neither weakness nor old age, but young, fresh and bright, greeting the twentieth century with kindness, and perennial vigor; and those fortunate enough to have a copy of this report, may appropriately say: "Well done! Pennsylvania Hospital."

**Personal Reminiscences and Recollections of Forty-six Years' Membership in the Medical Society of the District of Columbia, and residence in this city; with Biographical Sketches of many of the Deceased Members.** By SAMUEL C. BUSEY, M.D., LL.D. Cl., 8vo., pp. 373. Washington, D. C. 1895.

Dr. Busey has long been known as one of Washington's literary physicians; a fluent writer, and an eloquent speaker. His long identification with the medical work of the District, and his extensive acquaintance, enable him to speak on these topics with *ex-cathedra* utterance. His reminiscences of early life in Washington are interesting, not only to those whose lot is cast in the Capital City, but as well to young practitioners everywhere. His account is sometimes amusing:

"The prescribed fee for each visit was one dollar. Many times the bill was settled with a fraction, and often a small fraction of the amount, in fact the beginner took whatever he could get, and was glad to receive such portion, however large or small the bill might be."

Those who now see the beautiful city with the decorative effects that forty years fostering care by Congress has created, can scarcely realize what Washington was in the days of young Busey's advent, as amusingly set forth in this book. The account of his student life as a private pupil of Professor Geo. B. Wood, is a pleasing bit of medical history.

**A System of Surgery; by American Authors.** Edited by FREDERIC S. DENNIS, M.D., Professor of the Principles and Practice of Surgery, Bellevue Hospital Medical College, New York; President of the American Surgical Association, etc.; assisted by JOHN S. BILLINGS, M.D., LL.D., D. C. L., Deputy Surgeon-General, U. S. A. To be completed in four imperial octavo volumes, containing about 900 pages, each with index. Illustrated with figures in colors and in black. Volume I, 870 pages, 422 engravings and 2 colored plates. Price per volume: \$6 in cloth; \$7 in leather; \$8.50 in half morocco, gilt back and top. Philadelphia: Lea Brothers & Co. 1895.

There are forty-six contributors "named in the list," of whom twelve have contributed to this volume. The book appropriately opens with a condensed history of Surgery by Dr. John S. Billings. The assignment of this portion of the work to one who has the great Army library at his com-

mand is appropriate. We notice an inaccuracy in the five-line notice of the late Frank Hastings Hamilton, of New York. In the parenthesis the figures "(1813-66)" should be 1813-86, if, as is apparent, the year of the birth and death is meant by the figures. The last twenty years of the distinguished surgeon's life were by no means the least important. The chapter on Surgical Pathology, by Dr. W. T. Councilman, is the most satisfactory one hundred pages on this subject with which we are acquainted, and especially when taken in connection with the magnificent chapter by Professor W. H. Welch on the General Bacteriology of Surgical Infections. The chapters on Gunshot Wounds, by Dr. P. S. Conner; Fractures and Dislocations by Dr. Dennis; on Traumatic Fever, Erysipelas and Tetanus by Dr. J. Collins Warren and on Operative Surgery by Dr. Stephen Smith are noteworthy contributions. We have no hesitation in assigning this book to the first rank among the books of its class.

The weak point in most American works on surgery, judged by the European standard, has usually been the pathology, but no more competent hands than these could have been found in America, and we are proud to offer in this work a specimen of the quality of our new school of American Pathology, as promulgated by Welch, Councilman and Warren.

The mechanical execution of the book is worthy of the great publishing house that has issued it.

## NECROLOGY.

R. L. LUCKETT, M.D., of Boyce, La., died April 25 at his plantation near that town. After studying at Yale College, he took his medical degree at the New Orleans School of Medicine (now extinct), in 1860. He entered the Confederate ranks as private, but was promoted to surgeon's duty on the staffs of Generals Polk and Bragg. He was United States Marshal in 1894. He was in the lower house of his State Legislature from 1874 to 1879, and in the Senate for four years later.

EDWARD SHIPPEN, M.D., of Philadelphia, died April 23, aged 68 years. He was a native of that city and a graduate from the University of Pennsylvania, in the class of 1848. In the late war he was surgeon of the Artillery Reserves of his State and from 1861 to the end of the war, most of the time being with the Army of the Potomac. He was lineally descended from the senior Dr. William Shippen, who was one of the founders of the Pennsylvania Hospital, of the school that afterward became the University, and a trustee of the first medical college, and for thirty years a trustee of Princeton College.

MR. JOHN BIRD, of London, a blind surgeon and author of many publications on the condition of the blind, died late in April at the age of 84 years. He was preëminent in the profession for the efforts put forth for the amelioration of the lot of his fellow-sufferers. He became a member of the Royal College of Surgeons, England, and a Licentiate of the Apothecaries' Society in 1834, after pursuing his medical studies at St. Bartholomew's. Mr. Bird was the author of "Observations on the Neglected Condition of the Blind in England," the publication of which he followed by a "Lecture on the Capabilities, Rights, and Treatment of the Blind," and a "Letter on the Duty of Superseding the System of Exile Education of the Deaf and Dumb, as well as of the Blind, by Social Education, as recently established in the Communal Schools of Paris." This was published in 1856, and the same year he also wrote a biography of the blind James Wilson, and at other times contributed articles on social pathology and the needs of the deaf and dumb.

ARTHUR R. OPPENHEIMER, M.D., of Baltimore, Md., April 29, aged 22. He was first assistant resident physician of the Johns Hopkins Hospital.—Charles Ottilie, M.D., of La Crosse, Wis., April 30, aged 64.—Joseph Rowland, M.D., of Media, Pa., April 29, aged 82.—Elsie F. Anderson, M.D., of Valparaiso, Ind., April 29.—Thomas Seaton, M.D., of Bolivar, Pa., April 29, aged 82.—Spencer Byrne, M.D., of Marengo, Ind., April 28.

## PUBLIC HEALTH.

**Free Public Baths.**—The New York Legislature has enacted a law making it mandatory upon cities of that State having populations of over 50,000 inhabitants to establish free public baths, and authorizing cities with less than 50,000 inhabitants to raise money for a like purpose. Cleanliness, says the Hindu, is the key to heaven.

**Bacteriologic Laboratory for Paris.**—M. Dubois, on behalf of a special committee of the Municipal Council of Paris, presents a report advising the creation of a special laboratory for the bacteriologic examination of diphtheria. The committee is of opinion that there is urgent need of installing an official laboratory for gratuitous examination of microscopic preparations and cultures. Apart from the Pasteur Institute, which desires to be confined to its own sphere, the committee thinks there is no laboratory better qualified for this work than that of the microscopic and bacteriologic laboratory of Paris directed by Mignel. The Council voted an appropriation of 10,000 francs for this purpose.<sup>1</sup>

**Poisonous Dried Apples.**—United States Consular Agent Krauss at Zittau in Germany, reports to the Department of State that American evaporated apples offered for sale there have been submitted to a chemic analysis and found to contain oxid of zinc. The investigation was made at the instance of the police department, and samples were taken from three grocers. At the request of one of the merchants a chemist made an analysis of some of the apples, and certified that the quantity of zinc salt contained in a very large portion of apple jam made from the apples in question could convey into the human system about one-fifth as much zinc as may be given to infants without causing nausea. No case could be found, however, where the fruit had caused illness.

**The Hunger of the World.**—Mr. E. G. Ravenstein, the eminent English geographer and statistician, has made some calculations to find when the earth will be unable to find nourishment for its population and they will be forced to cannibalism or starvation. According to him when the number exceeds 5,994,000,000, or in round numbers, 6,000,000,000, this emergency will arise, and Mr. Ravenstein believes the population of the globe will reach this figure in 284 years more. He points out that the average decimal increase is 8 per cent., divided as follows: Europe, 8.7 per cent.; Asia, 6 per cent.; Africa, 10 per cent.; Australia and Oceanica, 30 per cent.; North America, 22 per cent.; South America, 15 per cent.

**Barbarism of Ignorance.**—A few weeks since a quarantine guard at Shawneetown, Ill., shot a citizen who was attempting to escape from a smallpox quarantine. On the 4th inst. a "pest-house riot" broke out at Winchester, Ky., where a colored prisoner in the county jail has smallpox. A building, erected five miles from the town for his reception, was burned down during the night, and the farmers armed with rifles are guarding the roads in anticipation that the smallpox prisoner may be taken through their neighborhood to some obscure locality. Meanwhile the sheriff, whose residence is in the jail, has his smallpox prisoner on his hands

and can not get him out of town. The barbarities of shot-gun quarantines are the results of ignorance and superstition—foster-parents of cruelty.

**Smallpox in Indiana and Ohio.**—Dr. C. N. Metcalf, Secretary of the Indiana State Board of Health, reports to the JOURNAL, under date of May 7, 1 case of smallpox at Terre Haute, 1 death; 2 cases at Evansville; 1 case at Indianapolis and 1 death at Tell City. Dr. Metcalf adds that the persons sick are all colored and the origin of the disease is not known.

Under the same date Dr. C. O. Probst, Secretary of the Ohio State Board, reports in Cincinnati 24 cases and 7 deaths, making in all 89 cases and 17 deaths; all cases have been taken to the Branch Hospital; 54 of the cases occurred in one square on the river front; all the inhabitants of this square have been vaccinated. In Cleveland 8 cases have been reported; the first cases were operatives in a woolen mill, and the origin of the disease is supposed to be infected rags; all of the cases have been removed to the Infectious Disease Hospital. No other cases reported in the State.

**Rewards of Early Rising.**—Aside from the helminthous property ascribed to the early bird by the adage, a recent newspaper writer implies that if one would become a healthy and well-preserved monarch all that is necessary is to acquire the habit of early rising. In support of his theory he cites the Emperor Francis Joseph of Austria, who invariably retires to rest at 9 and is up at 5—sometimes even at 4—in the morning and who is "athletic, elastic and youthfully active." King Humbert of Italy, likewise remarkably well-preserved, is also up with the lark and has taken his first breakfast long before the majority of his subjects are out of bed. Among the early risers Emperor William, the Queen Regent of Spain, King Charles of Roumania, King Oscar of Sweden, King Leopold of Belgium—indeed, says this writer, "it only requires a passing glance at the various thrones of Europe to show that those monarchs most healthy and well-preserved for their years are precisely those who, according to the new-fangled doctrine of the medical authorities, ought to be the ones most physically decrepit." The moral of which has been already pointed out: Get up early if you would be a healthy and well-preserved monarch.

**Effective Disinfection.**—Under the Sanitary Act of 1891 the sanitary authorities of London are bound to provide temporary shelter free of charge to all persons who are compelled to leave their dwellings for the purpose of enabling such dwellings to be disinfected. To what extent this obviously necessary measure is complied with is not definitely known, but the American reader will infer that like many other well-intended sanitary requirements it is more frequently honored in the breach than in the observance. Dr. Anthony Roche in a letter to the *Irish Times* calls attention to the London requirement with a view to securing its adoption in Dublin, whereupon the *Medical Press* says: "The requirement is but little known in the metropolis." As Dr. Roche points out, it is useless to disinfect infected premises if the occupants whose clothing is saturated with infection, are allowed to wander about the streets or carry the infection into neighboring premises.

**Influenza as a Factor of Increased Death Rates.**—The returns of deaths from influenza during the recent prevalence of this disease bear no relation to its actual influence on the mortality of the period. A very large percentage of the deaths from pneumonia, bronchitis, heart disease and kidney disease should be charged up to this insidious and protean malady. In a recent clinical lecture<sup>1</sup> Dr. James Tyson said: "Another serious danger of influenza is its tendency to con-

<sup>1</sup> Le Progres Medical.

<sup>1</sup> University Medical Magazine.

vert harmless, often latent, disease into serious disease. I especially refer to kidney and heart disease. One of the results of the more recent practice by the life-insurance companies, in examining the urine of all persons seeking insurance, is the discovery that albuminuria is present in many persons who are quite free from other symptoms—a condition not serious in itself. If such a man gets influenza, however, his mild albuminuria will sometimes become a serious one. The same is true of heart disease. A murmur unattended with other symptoms may, after an attack of influenza, become associated with other symptoms and assume a serious import."

**The Typhoid Milk Can.**—The recent distressing outbreak of typhoid fever in Stamford, Conn., traced unmistakably to the milk supply of one dealer, has awakened renewed interest in the question of the sanitary control of dairies and milk distribution. Dr. Welply, of Belfast, Ireland, has just issued a timely monograph on the subject—"Creameries and Infectious Diseases." He deals at some length with an outbreak of typhoid under his own observation in which the origin of the epidemic was traced beyond a doubt to the consumption of "separated milk" distributed from a creamery in the neighborhood. "Separated milk" is the skim milk left after the cream has been removed, to which is then added enough fresh milk to bring it just within the legal standard, and it is then sold as new milk in the large towns. As the creamery receives the milk from several dairies, one infected supply may pollute the product of all the others contributed to the same creamery, and in this way a single case of rural typhoid may become almost infinitely multiplied. Dr. Welply traced up such an infected dairy as the cause of the outbreak, and then goes on to show how minute a quantity of the morbid matter is capable of wellnigh indefinite multiplication in such an ideal culture medium as milk. He found in his examination that the cows in this dairy were milked by a person whose hands had been soiled by typhoid dejecta and that some of the dairy maids acted also as nurses to the sick. Among other practical points he refers to the fact that few cows can be thoroughly milked unless the hand and the teat be kept moist, to which end the majority of milkers wet both surfaces with the first portion of milk that is drawn. Dr. Welply advocates two principal measures of prevention—first, thorough and frequent dairy inspection by competent and independent inspectors; and secondly, compulsory notification of all cases of illness occurring in dairies which send milk to creameries.

**Health Reports.**—Sanitary reports to the Supervising Surgeon-General, Marine-Hospital Service.

#### SMALLPOX—FOREIGN.

Argentina Republic: Buenos Ayres, month of February, 10 deaths.

Austria: Buda-Pesth, April 1 to 8, 3 cases.

Bohemia: Prague, April 6 to 13, 3 cases.

Brazil: Rio de Janeiro, March 23 to 30, 3 deaths.

Egypt: Alexandria, March 19 to 25, 4 cases, 1 death; Cairo, 3 cases, 3 deaths.

England: South Shields, April 13 to 20, 6 cases; Birmingham, April 6 to 13, 1 case, 1 death; Liverpool, April 6 to 13, 1 case—April 13 to 20, 5 cases, 1 death; London, April 13 to 20, 4 cases; Manchester, April 13 to 20, 1 case.

Holland: Amsterdam, April 13 to 20, 1 death; Rotterdam, April 13 to 20, 5 cases, 2 deaths.

India: Calcutta, March 16 to 23, 233 deaths.

Ireland: Dublin, April 6 to 13, 10 cases, 2 deaths—April 13 to 20, 8 cases—for three months ended March 30, 642 cases, 81 deaths.

Scotland: Edinburgh, April 1 to 6, 7 cases, 1 death—April 6 to 13, 3 cases—April 13 to 20, 2 cases 1 death; Glasgow, April 13 to 20, 8 deaths.

Russia: Batoum, April 3 to 10, 8 cases, 1 death; Moscow, April 1 to 6, 2 cases, 2 deaths; Odessa, April 1 to 13, 1 case; Warsaw, April 1 to 6, 1 death; St. Petersburg, April 6 to 13, 1 death.

West Indies: San Juan de Porto Rico, April 3 to 10, 1 death—April 10 to 17, 1 death.

#### SMALLPOX—UNITED STATES.

Arizona: Nogales, May 2, 39 cases.

Florida: Key West, May 4, 1 case.

Indiana: Evansville, April 30, 2 cases.

Michigan: Smallpox reported at Detroit and Brownstown Township, during week of April 20 to 27.

Mississippi: Vicksburg, May 1, 2 cases.

New Hampshire: Claremont, April 20 to May 3, 11 cases; Croydon, 7 cases; Newport, 1 case.

New Jersey: Hoboken, April 20 to 27, 2 cases.

Ohio: Cincinnati, April 27 to May 4, 11 cases, 1 death.

Pennsylvania: Philadelphia, April 20 to 27, 10 cases.

West Virginia: Wheeling, March 25 to May 3, 12 cases, 1 death.

#### YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, March 23 to 30, 20 deaths; Santos, March 23 to 30, 108 cases, 87 deaths.

Cuba: Havana, April 18 to 25, 3 cases, 1 death; Santiago de Cuba, April 1 to 28, 10 deaths.

#### CHOLERA—FOREIGN.

Argentina: Buenos Ayres, February 1 to 28, 45 deaths.

India: Madras, March 23 to 30, 1 death; Calcutta, March 16 to 23, 103 deaths.

Arabia: Camaran quarantine station. Cholera was brought to the station by the S.S. *Mohamed* and the S.S. *Yubeda*. March 23 to 30, 48 cases, 13 deaths.

## SELECTIONS.

**Surgical Tuberculosis.**—Isnardi (Turin, 1894,) reports success in the use of oil of turpentine. He uses this partly as an ointment with vaselin, equal parts, in affections of the skin, partly undiluted as an injection into fistulas or abscesses. Fistulas are first curetted, and abscesses are aspirated. Very intense inflammation follows with rise of temperature to 40 degrees C., but with no severe general symptoms. In four to six days abscesses are to be incised, packed with sterilized gauze containing the turpentine ointment. The results, as detailed by the writer in eighteen cases in children were most promising.—*Centralblatt fur Chirurgie*.

**Treatment of Leukoplakia.**—L. Leistikow, in *Monatsheft fur praktische Dermatologie*, 1894, No. 3. Leukoplakia of the mouth is generally very hard to influence therapeutically; for this reason every new remedy meets with ready trial. The success which the writer had with patients who had had syphilis, but in whom specific remedies proved useless, was worthy of note. Several times a day especially after meals and at bedtime, the following paste was applied with a swab: terre silicee, 1.5, resorcin 3, adipis 0.5. After eight to fourteen days a shriveling was noticed; then the slightly inflamed mucous membrane was brought to a normal condition best by balsam of Peru. The accompanying hyperplasia of the lower lip was also diminished, but eventually the cauterization had to be repeated two or three times.—*Centralblatt fur Chirurgie*.

**Hydatid Fremitus and Resonance.**—(*Policlinico*, 1894, No. 11) Santini drew the attention of the Academy of Sienna to the fact that a deep sonorous tone is heard on percussing an echinococcus cyst, if at the same time one listens with the stethoscope. Ravogli proved this statement on one living subject and also on the extirpated cyst, afterward also experimentally on India rubber bladders. He therefore arrives at the following conclusions: echinococcus cysts yield not only the feeling of the so-called hydatid fremitus on palpation and percussion, but also to coincident auscultation a characteristic tone, the hydatid resonance. To find these signs often requires no little pains. Failure is quite possible if the cyst wall is very thick or has degenerated, if the contents are more or less thick, and finally, if the cyst lies too deep and is covered with thick layers of tissue. The best method of examination is to place the left hand firmly

on the tumor and to percuss the terminal phalanges with the middle finger of the right hand. The hydatid resonance is more easily found than the fremitus, and may be recognized in cases in which the latter symptom is missed.

In ovarian cysts containing thin fluid, hepatic abscesses, etc., neither of these symptoms was ever found. Elasticity and extensibility of the cyst wall, and clear contents are necessary for their production.—*Centralblatt für innere Medizin.*

**Ether for Anesthesia in Munich.**—(P. Ziegler, *Munchener med. Wochenschrift*, 1894, No XXIII.) Ether has been used at the surgical clinic in Munich since May 1, 1893. The experience in 600 cases is now made public. . . . In conclusion, the unpleasant sensation of suffocation at the beginning, the cyanosis, the excessive secretion of mucus and saliva, the tardy relaxation so common in alcoholics, the frequent partial return to consciousness when the cone is removed, are annoying, but can be obviated by greater experience. Over against these is the diminished danger, since cardiac syncope is not primary, but secondary to respiratory syncope, which can be more easily overcome. Ether is not recommended for operations on the face, and is directly contraindicated in all diseases of the air passages, including compression of the trachea. He declares himself in favor of the use of ether, and the latest statistics justify him, for 1 death has resulted in 1,900 cases of chloroform anesthesia, while with ether, 1 death in 26,000 cases.—*Centralblatt für Gynäkologie.*

**Heteromorphism of Bacteria under the Influence of Lithium Salts.**—Herbst, in the domain of zoology, by the addition of lithium and potassium salts to sea water, saw the eggs of the sea-urchin (*Echinus microtuberculosis*) assume a different, hitherto unknown formation; reasoning by analogy, Gamaleia (*Wratsch*, 1894, Nos. 19 and 20) tried the effect of lithium on various bacteria and recorded a series of altered forms resulting.

Twenty-four hours after the addition of .5 to 1 per cent lithium chlorid to a cholera bouillon culture or 1 to 2 per cent to a cholera agar culture: 1, giant spirilla were seen, having considerable length and breadth, unequal thickness and distinctly corkscrew-like cells; 2, further, especially if the percentage of the lithium salts be increased, spherical or amoeboid cells. The spherical forms were in general easily stained, wholly or only in part, by alkaline aniline dyes; often the contents of these forms were finely grained with crystalline luster or pierced by lines or rods. A third and less common form displayed very fine filaments, which, if pressed more firmly together, formed a fine felt-like tissue. Here and there the impression is given that these filaments are offshoots from the thick spirilla.

In contradistinction to the involution forms which arise in decaying colonies, Gamaleia calls this transformation, heteromorphism, a term introduced by himself, since the forms he describes are found in fresh cultures and there is no appearance of degeneration, as is manifest from the imperfection of the heteromorphous forms, from their quantitative preponderance over the number of normal bacteria in the preparation, further from their larger size, their ease in staining and from the absence of the fine-grained, coccus-like destruction, characteristic of old cultures. Besides, the term, heteromorphism, is least prejudicial to the question as to the retrospective or prospective character of the forms.

Typhus bacilli showed after the addition of lithium chlorid to cultures exactly the same three types of changed forms. Other forms of bacteria, as milzbrand and diphtheria, showed no tendency to heteromorphism, nor was there any such manifestation, if sodium, potassium, caesium or rubidium were added to cholera or typhus cultures. As to the viability of the heteromorphous bacteria, it is to be noted that the giant forms have vital energy and retain their characteristics after inoculation on common gelatin. The viability of the other forms seems undecided. But, on the other hand, bacteria may acquire a certain indifference to the action of lithium, for successive inoculations on nutrient media containing the same proportion of lithium lead to a decline and disappearance of the heteromorphism.—*Centralblatt für innere Medizin.*

## MISCELLANY.

**Addresses at the Forty-seventh Annual Meeting.**—(By telegraph to the JOURNAL).—The addresses at the Forty-seventh Annual Meeting of the AMERICAN MEDICAL ASSOCIATION will be delivered by Nicholas Senn, M.D., Chicago, on Surgery; William Osler, M.D., Baltimore, on Medicine; George H. Rohé, M.D., Baltimore, on State Medicine.

**St. Francis Hospital, New York.**—Under the will of the late Mansay P. Dódin, the sum of \$1,000 was recently made over to the Sisters of the Poor who conduct the hospital above named.

**The Willard State Hospital for the Insane, New York.**—A destructive fire, without loss of life, broke out at this institution on the 28th ultimo, and consumed property valued at \$150,000. The entire institution was in danger at one time, and all the patients were gotten ready to vacate.

**Reduction in the Price of Antitoxin.**—The New York City Board of Health has recently reduced the cost of the serum produced by its Bacteriologic Bureau, as follows: "First quality, from \$1.25 to 75 cents; second quality, \$2.50 to \$1.50; third quality, \$4 to \$3." The Board will continue to supply charitable institutions and poor patients free.

**An Accumulative Doctor.**—A Socialist member of the Belgian Parliament receives \$700 per annum as physician to the lock hospital, \$320 as physician to other hospitals, beside \$200 for his services in the custom house. Add to this \$800 for his parliamentary services, and the *Gazette Medicale de Liège* thinks the doctor should contrive to live on his practice.

**Dr. Max Simon Nordau**, the author of "Degeneration," is a medically educated man. He was born at Buda-Pesth in 1849, took his medical degree in 1873, traveled and studied medicine for five years, at the end of which time he made his permanent home in Paris. He became a correspondent of the *Frankfurter Zeitung* and other German journals, also contributing social and political writings to various French reviews, some of which attracted marked notice.

**Dr. A. Conan Doyle**, whose books have had a great circulation in this country, came hither last winter to deliver lectures. From certain comments in the papers it would appear that the rewards of this visit were not such as to lead to its repetition. In fact, in the *World*, Dr. Doyle has stated that he does not care to visit America again in the winter season, for the reason that our "railroad cars are kept too hot." The *World* suggests that really he found that his audiences were too cool for him.

**David S. Ingalls.**—The late David S. Ingalls, of Springville, New York, left an estate valued at over \$600,000, the most of which was bequeathed to charitable institutions. The will was hotly contested by two surviving sisters and a niece. One of the sisters was alleged to be of unsound mind. The contest has been "on" since early in 1893. The hospitals and other charitable legatees will receive about two-thirds of the estate, the contesting relations and counsel will get one-third, nearly.

**Wound of the Bladder During Vaginal Hysterectomy.**—Jacobs reports that after incising the vaginal mucous membrane in the anterior cul-de-sac, which would allow him to place the utero-vaginal sutures, he proceeded with the finger to detach the cellular tissue separating the supra-vaginal portion of the cervix from the bladder, when suddenly and without any warning the index disappeared in the bladder. The author sutured the viscus at once and found then that the muscular fibers of the vesical wall only existed in patches, consequently the suturing was very laborious but

it was finally accomplished with fine catgut in two stages. Owing to this accident the vaginal method was abandoned; ten days later, the fistula having closed, abdominal hysterectomy was performed with recovery.<sup>1</sup>

**Iodid of Potash in Actinomycosis.**—Berard has collected all the cases of actinomycosis in which iodid of potash has been used. This treatment has brought about recovery in about 95 per cent. The iodid of potash may then be considered as a specific for this affection. What is the mode of action of the medicament? The experiments of Berard show that the actinomycetes grow readily in cultures to which iodine has been added. It seems probable, then, that the iodid of potash acts especially on the anatomic elements.<sup>2</sup>

**Treatment of Nasal Hypertrophy.**—At a recent meeting of the Paris Academy of Medicine, Lucas-Championniere showed a patient affected with nasal hypertrophy from acne. Ollier's method—decortication by the thermo-cautery without autoplasty and with a simple, weak antiseptic dressing—had given a very good result. The only difficulty is not to clog the nostrils and to touch the septum as little as possible during the decortication. Marc See stated that, instead of decorticating all the nose, he leaves strips of skin between the cauterized areas; his method, which he has used for fifteen years, may be done without chloroform. In replying, Championniere maintained that in cases as complex as the one he presented, total decortication is preferable; it gives a more complete and especially a much more rapid result.<sup>3</sup>

**Contra-indicated During Pregnancy.**—Huguenin mentions as chief of the remedies which are dangerous to the pregnant woman, salicylate of soda and ergot. Purgatives—castor oil, mineral salts and especially aloes—should be avoided. Oxalic acid and its salts—oxalate of potash, etc.—may prove dangerous. Antipyrin frequently taken inhibits the lacteal secretion; cocain locally applied for fissured nipples has the same effect, and should be proscribed for nursing women. As to operative measures, they are not absolutely contra-indicated; we may, for example, extirpate a peri-uterine tumor, the development of which hinders pregnancy, provided the operation is speedy and little blood lost. It is better to wait until the fourth or fifth month before operating. Operations in the vagina or uterus, no matter how minor, should be avoided in order to avoid suspicions of abortion in the patient's mind.<sup>4</sup>

**Action of the Nervous System on the Lymphatics.**—The study of the innervation of lymphatic vessels presents great difficulties and our knowledge of the subject is confined to some vague and incomplete notions. MM. Camus and Gley have tried to fill this gap by a series of ingenious and demonstrative experiments. These physiologists have been able to register the movements of the receptaculum chyli and the thoracic duct in the dog. By exciting the trunk of the left splanchnic nerve or the thoracic sympathetic they cause, according to conditions, dilatation and contraction of the receptaculum and duct. Hence there are in the same nerve trunk constrictor and dilator fibers for the same vessel, but the latter predominate. This contractility of the lymphatics under the influence of the nervous system plays a considerable rôle in the lymph circulation. The alternate movements of dilatation and contraction are somewhat important in certain cases, for they may be compared to the lymph hearts of certain lower vertebrates. These experiments also show that local circulations may be produced in the lymph vessels as in the blood vessels.<sup>5</sup>

**Professor Huebner of Berlin on Antitoxin.**—The address, before the Thirteenth Congress for Medicine, at Munich early

in April, by Professor Huebner, touches upon the present treatment of diphtheria at the Berlin hospitals. He holds that the statistics there show a marked reduction in the rate of mortality by that disease since the introduction of the use of the serum. He notices that the tendency of the membrane to spread to new localities is reduced. Out of 181 cases there was such spread in only 16 cases. A spread of the disease to the larynx was not observed; in 19 per cent. exanthems were produced; in a few cases fever followed the injections, and in fewer yet there was pain in the joints. The latter was transient and produced no injury to the system. The immunizing property of the serum was not of long duration. The concluding paragraphs of this address are interesting, as given below from the *Medical Press*, for April 24: "He had never believed a remedy would have such a great influence, such an immediate action; he had never believed himself so much indebted to a physician as to the discoverer of diphtheria curative serum. With confidence, he concluded, we could proceed to the building up of our experience, with good conscience we could call out to every colleague: "Prove for thyself and prove as often as thou canst, enough of the noble metal is here. How high its carat, to determine that requires the inexorable scales of time. Art, however, has the time, for it is long."

**Hydatid Cysts of the Lung.**—Behr insists on the great importance of the question of infection or non-infection which governs at the same time the evolution and the pathologic anatomy of cysts of the lung. In the latter case the hydatid is an aseptic foreign body which only reveals its presence by symptoms of compression. In the former it is not long tolerated by the tissues and numerous complications ensue. As regards the penetration of the six-hooked embryo the generally accepted opinion is that it is transported by the veins through the hepatic filter to the right ventricle and thence into the pulmonary capillaries. The dimensions of the embryo of the hepatic capillaries render this opinion probable. Nevertheless the invasion by the air passages seems none the less probable and is admitted, especially in Australia where hydatids of the lungs are relatively frequent. The eggs of the tænia may very easily become mixed with dust and be thus inspired. Diagnosis is very difficult, because there are no pathognomonic symptoms and often the small cysts are only discovered at the necropsy. The most constant sign is dyspnea and its intensity depends on the volume and situation of the tumor and the patient's respiratory capacity. Cysts in the upper part of the lungs seem to give rise to more intense dyspnea than those at the base, even if of the same size. Pain is the second important symptom for "hydatids of the chest are often more painful than those of any other region." The pain is acute, persistent, with exacerbations and may radiate far beyond the part affected.<sup>1</sup>

**Therapeutic Applications of Anemonin.**—Anemonin has been extolled in the treatment of bronchial catarrh, in convulsive coughs and in asthma. The dose is from 2 to 4 centigrams daily in capsules or alcoholic solution. Larger doses cause cephalalgia and a feeling of weight in the extremities. In amenorrhea and dysmenorrhea Bovet has used it in doses of 5 to 10 centigrams daily—but never to exceed 20. According to this author it is the analgesic *par excellence* for uterine disorders. It is easily decomposed in the intestine, however, so its action is uncertain. *Anemone pulsatilla*, in the form of tincture, was highly extolled in 1882 by Schapter for reflex eclampsia, palpitations, ephemeral febrile conditions following violent emotions or fatigue, hay fever—in short, in all neuroses of sympathetic origin. For these he prescribed 20 to 100 drops of the tincture in increasing doses. E. Martel advises the treatment of acute orchitis by tincture of anemone—20 drops daily in divided doses. Martel says that by its use the pain is much diminished and that it has a tendency

<sup>1</sup> These de Paris.

<sup>4</sup> Le Progres Medical.

<sup>5</sup> Arch. de Gynecol.

<sup>1</sup> These de Paris.

to resolve the inflammatory process. Anemonin, extracted from the above plant and studied by Bronvsky in 1886, is very toxic. Two grams injected under the skin of dogs caused death in twenty-four to thirty-six hours after increasing dyspnea, slowing of the heart, torpor and paralysis. Death seemed due to cardiac paralysis. Bronvsky has used anemonin with success in bronchial catarrh, asthma and convulsive coughs. He gives 5 to 10 centigrams daily in the form of powder in two doses.<sup>1</sup>

**Before or After?**—How many physicians direct the time of taking medicine on well-defined chemico-physiologic principles? The *Medical and Surgical Reporter* has attempted to furnish such principles in the following: Iodin and iodids should be given on an empty stomach, when they rapidly diffuse into the blood; if given during digestion the acids and starch alter and weaken the action. Acids, as a rule, should be given between the digestive acts, because the mucous membrane of the stomach is then in a favorable condition for the diffusion of acids into the blood. Acids may be given before food when prescribed to check the excessive formation of the acids of the gastric juice. By giving it before meals you check the osmosis stomach-ward of the acid-forming materials. Irritating and dangerous drugs, —such as salts of arsenic, copper, zinc, and iron—should be given directly after food, except where local conditions require their administration in small doses before food. Oxid and nitrate of silver should be given after the process of digestion is ended; if given during digestion, chemic reactions destroy or impair their special attributes and defeat the object for which they were prescribed. Metallic salts, especially corrosive sublimate and also tannin and pure alcohol, impair the digestive power of the active principle of the gastric juice, so should appear in the stomach during its period of inactivity. Malt extracts, cod-liver oil, phosphates, etc., should be given with or directly after food, so that they may enter the blood with the products of digestion.

#### Hospital Notes.

**ST. CLAIR STREET HOSPITAL.**—At a meeting of the St. Clair Street Hospital trustees held in Cleveland, Ohio, April 21, it was decided to proceed at once with the erection of the proposed hospital annex; estimated cost \$2,500.—**St. Luke's Hospital at Davenport, Iowa,** was formally opened April 30.—**The Lamar Hospital, at Augusta, Ga.,** has been formally opened.—A movement is on foot to establish a public hospital at Tiffin, Ohio.—Plans have been made for the enlargement of St. Bernard's Hospital at Council Bluffs, Iowa. The probable cost of the addition will be \$40,000.—**The corner stone of the Vermilion County Hospital, Illinois,** was laid May 11. Many secret societies participated in the event.—**The managers of the Pennsylvania Hospital at their annual meeting held May 6,** elected Dr. James C. Wilson to the medical staff as attending physician, in place of Dr. Morris Longstreth.—**The new memorial surgical pavilions of the Pennsylvania Hospital** were inspected by the contributors and managers and will shortly be utilized for patients, thus nearly doubling the capacity of the hospital.—**The recently issued "History of the Pennsylvania Hospital,"** by Dr. Thos. G. Morton, assisted by Dr. Frank Woodbury, was presented to the contributors at this meeting and a formal vote of thanks therefor was passed unanimously.

#### Louisville Notes.

**SMALLPOX.**—Special Examiner Long reports from Princeton that there are sixteen cases at that place, with three exceptions all occurring in the persons of negroes. This prevalence has been due to the fact that the local authorities did not know that the law compelled all infected persons to be confined in the local pest-house,—and there has been

a free communication between the cases and unvaccinated persons.

**CITY HOSPITAL.**—The four regular schools have furnished the Board of Public Safety with a list of physicians and surgeons who are to represent them upon the visiting and consulting staff for the coming year. It is stated that there will be no conflict between the two schools of medicine and everything seems to be adjusted satisfactorily.

**DEATH REPORT.**—The report for the past week shows a total of 62 deaths. Of these 4 were due to typhoid fever, 12 to pneumonia. There were 2 stillbirths. The report for the month of April shows a total of 366 deaths. There were 43 deaths from consumption, 4 from puerperal fever, 9 from typhoid fever, and 98 from pneumonia. There were 201 males and 165 females, 258 white, 108 colored. Sixteen deaths occurred at the City Hospital and one at the eruptive hospital from smallpox. The death rate for the month was only 1.5 per 1,000 of the white population and 3 per 1,000 among the colored people.

**Good Roads.**—Our country practitioners are so much interested in the subject of good roads that we give place to the following:

#### STATE ROADS IN MASSACHUSETTS.

For the past three years the press of the United States has so thoroughly discussed the different advantages of good roads, and so universally indorsed this reform, that all classes of our citizens appreciate the necessity of, and are anxious for, the immediate adoption of such laws as will hasten the construction of State highways. Massachusetts has from the outset taken the lead in this matter, and the spirit of her Legislature has been shown by making the Highway Commission a permanent one, and by appropriating \$300,000 to be expended, under the immediate supervision of the Commission, in constructing new and rebuilding old roads. As a natural result of the popular agitation and the monster petition, which I had the honor to present to Congress in 1893, the United States recognized the necessity of a move in this direction, and under the "Agricultural Bill" made a special appropriation of \$10,000 to meet the expense of a careful investigation into the condition of roads throughout the country, and for the publication of such information as would assist the people in bettering their highways. The Department of Agriculture has issued a number of bulletins, and it is gratifying to learn that more than a score of States have already passed new road laws, while nearly all the others are planning for the adoption of measures for the promotion of this reform. Experience has shown that the course pursued by Massachusetts is the one which commends itself most strongly, both to the people at large and to their legal representatives, the various State Legislatures, and it is natural to suppose that if all were familiar with the work here the knowledge would be utilized to bring about similar legislation wherever the method of procedure is still unsettled. For this reason I would call to your attention and urge upon you the advisability of enlightening your readers on the good work we have already accomplished. Starting in June, 1892, a Temporary Commission was appointed to examine into the condition of the roads, and to draft a bill providing for the improvement of the highways of the Commonwealth. The law suggested by the Commission was, with some changes, passed in June, 1893, but, before any petitions for construction of State highways were submitted to the General Court, an act was introduced and passed June 20, 1894, increasing the powers of the Commission, and permitting the selectmen of any town, or the mayor and aldermen of any city, as well as county commissioners, to petition the Highway Commission for taking roads as State highways. In place of submitting to the Legislature a separate bill for the construction of each road, it was voted that the appropriation be used by the Highway Commission, without further legislation, in building State highways. The \$300,000 has been pretty evenly divided among fourteen counties. Before deciding which of the many petitions should be granted an official visit was paid to each locality, and full information as to the value of the proposed improvement collected. While this method has distributed the work in small sections of roads, thus increasing the expense per mile, the advantage to the people at large will be still greater, for the reason that each portion of the State highway constructed is intended to be an object lesson to those living near by.

<sup>1</sup> Les Nouveaux Remedes.

County commissioners and other officers will watch the work as it progresses, and follow out the same lines in building county and other roads which are not intended for State highways. The plan is to build, section by section, such roads as will connect the great centers of trade, and join with through roads in other States, so that both local and interstate communication will be benefited. Under date of January, 1895, the Massachusetts Highway Commission has rendered a report which covers the work of the past year, and this publication should be consulted by those who are considering legislation. The provisions of our law will permit contracts for the construction to be let to municipalities or to private corporations, but the former arrangement is preferred, as it is more effectual in teaching the people the art of road building, and protects the State against cheapening the work by the importation of foreign laborers, an element which is apt to be objectionable. A resident engineer is appointed by the Commission, and it is his duty to be in attendance, and keep a correct account of all items to be paid for by the State. Wherever the traffic was of sufficient proportions to warrant it the roads have been broadened. The advantage to owners derived from the construction of the way is, as a rule, so much greater than the injury to them by widening the road that, in a large majority of cases, the town officers have been able to procure releases without any cost. Thirty-eight sections have been contracted for, and only eight of them are to have a width of eighteen feet of hardened surface, all others being fifteen feet wide. As the primary object is to get length of way, the Commissioners are considering the advisability of building single-track roads in the thinly-settled districts. These would not be over nine feet wide, with here and there portions of double width as convenient passing points for carriages. A mile and a half of such roads can be built for less than the cost of a mile of fifteen feet width, and the advantage in getting produce to market is not lessened, provided such construction is confined to localities where the average traffic is from six to eight vehicles an hour. There is need of legislation to regulate the care of, and responsibility for, sidewalks on State highways. These being of purely local advantage should be under the supervision of the town, the wheelways alone being constructed and kept in order by the State. Progress has been made in the laboratory work on the road building stones of the State. Experiments of this kind are carried on at Harvard University in the Lawrence Scientific School, whose Dean, Prof. N. S. Shaler, is a member of the Highway Commission. The chief aim of these inquiries has been to determine the qualities which constitute fitness for road making. This will be of value to the Commission in enabling them to utilize the road material near at hand, and thus lessen the cost of construction. As this phase of the work progresses, maps are made showing the location of all deposits suitable for road building. A number of towns have already appropriated money to build their streets in the same careful manner as those constructed by the State, and others have purchased road machinery with the intention of extending the work on roads other than State highways. Careful consideration has been given to the plan of planting shade trees along the highways. With this end in view, experts have been consulted concerning the best varieties for the purpose, and the wayside trees have been examined, so as to determine the species well adapted to the climate and soil of Massachusetts. As the estimated expense of procuring and planting these trees is not less than \$500,000, the Commission has rightly made this question secondary to road building, but in the meantime they are collecting such data as will enable them to work with profit on the adornment of the roads after the construction is well in hand. The American and English elms have the advantage of fairly rapid growth, with shade high above ground, and the leaves falling from them give but little obstruction to the gutters. They have the disadvantage of being subject to the attacks of insects, so that the cost of protecting them from these pests would be considerable. Maples grow well and are beautiful, though they often shade the road too much. It is the custom in parts of Europe to plant the roadsides with trees which yield profitable crops. In France and Germany, for example, cherry trees abound. In these countries the yield of the wayside trees belongs to the neighboring land owners, but in some cases to the community, and their product is well guarded by law. There will be more or less experimenting on the part of the Commission before they decide upon the species to be planted. The law provides for the beginning of this work in the spring of 1895, and from that time it will be carried on slowly, so as to give us the benefit of experience. Every State should make a beginning

on road improvement. In thinly-settled regions of the country, where the people do not feel able to undertake much they can do no better than to start the reform by constructing sections of single-track roads. No community can afford to neglect the common roadways. Our prosperity is too intimately connected with the facilities for communication. I have spent many thousands of dollars in inaugurating and advancing this reform, and continue to take an active part in it, though for a long time I have not addressed you on the subject. The interest is now general, and the leaders numerous, consequently there is a demand for road news, more especially for the recent advancements in the line of actual experience. Here is what we have done in the old Bay State. Will you not publish it, or a portion of it, for the benefit of your readers, many of whom, without doubt, are directly or indirectly connected with, or interested in the development of the cause? Very truly yours,  
 Boston, Mass. ALBERT A. POPE.

## THE PUBLIC SERVICES.

**Army Changes.** Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from April 27, 1895, to May 3, 1895.

First Lieut. HENRY D. SNYDER, Asst. Surgeon U. S. A., is granted leave of absence for two months, to take effect upon the conclusion of his examination to determine his fitness for promotion.

**Navy Changes.** Changes in the Medical Corps of the U. S. Navy for the week ending May 4, 1895.

P. A. Surgeon E. R. STITT, detached from U. S. S. "Chicago," and to Nicaragua Canal Board inspection of work on the Isthmus.

Surgeon H. G. BEYER, detached from Naval Academy, and to the "Monongahela."

P. A. Surgeon L. W. ATLEE, from the New York Hospital, and to the "Richmond."

P. A. Surgeon J. M. EDGAR, from the "Richmond," and to the school ship "Saratoga."

P. A. Surgeon V. C. B. MEANS, from the "Saratoga," and to the New York Hospital.

Asst. Surgeon ROBERT BOYD, from Philadelphia Hospital, and to the "Monongahela."

Asst. Surgeon LEWIS MORRIS, ordered to the Philadelphia Naval Hospital.

**Marine-Hospital Changes.** Official list of changes of stations and duties of medical officers of the U. S. Marine-Hospital Service, for the fifteen days ended April 30, 1895.

Surgeon C. S. D. FESSENDEN, detailed for duty on board for examination of officers, revenue cutter service, April 17, 1895.

Surgeon J. B. HAMILTON, granted leave of absence for twelve days, April 20, 1895.

Surgeon G. W. STONER, detailed to represent Service at meeting of AMERICAN MEDICAL ASSOCIATION, April 25, 1895.

Surgeon F. W. MEAD, detailed as chairman of board for physical examination of officers, revenue cutter service, April 17, 1895.

P. A. Surgeon C. E. BANKS, when relieved, to report at Bureau for duty as chief of purveying division, April 24, 1895. Granted leave of absence for fourteen days, April 29, 1895.

P. A. Surgeon L. L. WILLIAMS, detailed for duty on board for examination of officers, revenue cutter service, April 17, 1895.

P. A. Surgeon W. P. MCINTOSH, detailed for duty on board for examination of officers, revenue cutter service, April 17, 1895.

P. A. Surgeon J. J. KINYOUN, detailed to represent Service at meeting of AMERICAN MEDICAL ASSOCIATION, April 25, 1895.

P. A. Surgeon R. M. WOODWARD, to proceed to Ashtabula, Ohio, as inspector, April 19, 1895.

P. A. Surgeon C. P. WERTENBAKER, granted leave of absence for ten days, April 16, 1895.

P. A. Surgeon B. W. BROWN, detailed as recorder of board for physical examination of officers, revenue cutter service, April 17, 1895. Granted leave of absence for twenty days, April 28, 1895.

Asst. Surgeon W. J. S. STEWART, to rejoin station at Washington, D. C., April 20, 1895.

Asst. Surgeon EMIL PROCHAZKA, to proceed to Evansville, Ind., for temporary duty, April 29, 1895.

Asst. Surgeon A. R. THOMAS, granted leave of absence for thirty days, April 19, 1895.

## ADDRESSES.

### ADDRESS ON GENERAL MEDICINE.

#### THE MALARIAL DISORDERS OF LARGE CITIES, WITH ESPECIAL REFERENCE TO CHICAGO.

Delivered at the Forty-sixth Annual Meeting of the American Medical Association, held at Baltimore, Md., May 7-10, 1895.

BY WM. E. QUINE, M.D.

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE COLLEGE OF  
PHYSICIANS AND SURGEONS OF CHICAGO AND PRESIDENT OF THE  
FACULTY; PRESIDENT ILLINOIS STATE BOARD OF HEALTH, ETC.  
CHICAGO.

It is a fact of familiar observation and comment that irregular cases of malarial disorder are occasionally met with at all seasons of the year and in all localities. It is equally well known that the conditions existing in large cities are inimical to the production of the malarial poison. The busiest metropolitan physician sees very few examples of frank periodical malarial fever that unquestionably originated in paved and sewered portions of his city. The rare cases that do occur are accounted for upon the assumption of "limited foci" of infection. If an excavation for building purposes is found in the neighborhood, no matter what the season of the year, it is readily assumed that the upturning of the soil is the cause of the patient's sickness. Or, if the individual has been out of the city, at any time within a period of a year or two, it is taken for granted with equal promptitude and with equal lack of knowledge of the truth, that he received the infection at that time, and that it has been sleeping or "latent" in his body ever since; and if he actually visited a region known to be malarious, even though it were several years before, the discovery of the fact is regarded as having almost the force of a demonstration of the exact time and place of intoxication. And, if no recent excavation can be discovered and no absence from the city has occurred, it is nevertheless unyieldingly maintained that some subtle emanation from the soil, somewhere, must be held responsible for the result.

In considering this problem it is well to include the questions of season, climate and locality. Contemplate the climate of Chicago between November and March when the earth is frozen to a depth of a foot or more, a good part of the time, and also covered with frozen snow—to say nothing of macadamized pavement; when the temperature has been below zero for a month and below the freezing point for several months; when building operations have been arrested and a recent excavation can not be found anywhere; and then try to account for the malarial affections that prevail on the finest avenues and boulevards of that city during and between the months named, by assuming that there has been some subtle morbid emanation from the soil!

The country surrounding the head of Lake Michigan was intensely miasmatic before it became densely populated and comparatively well drained; and the environs of Chicago are miasmatic still. Modern treatises say that the presence of malarial disorders in the region of the Great Lakes is not extensive, but is limited mainly to the vicinity of Lake St. Clair and the southern shore of Lake Erie. I have believed and maintained for many years that there were no such disorders in Chicago, that originated in finished portions of the city, except here and there a chance case from fresh upturnings of the soil. I used to think that malarial infection was easily recognizable, except in rare instances, on the basis of a strong individuality of its symptomatology; but now I think cases are common in which no man that lives or ever has lived can make a reliable diagnosis on a basis of their external phenomena. I also think that I have been seeing such cases all my life and labeling them "irregular typhoid fever" and "rheumatism" and "grippe" and "purpura hemorrhagica," or something else. I used to refer to the word "malaria" as the refuge of ignorance—and it was, and is, and will continue to be used by doctors when they do not know what is the matter with their patients. But when the diagnosis is supported by a microscopic demonstration it is different. We can ridicule an opinion but we must make obeisance to a fact. In this day, diagnosis is not always a mere matter of judgment. It may be a matter of demonstration. For purposes of medical literature and debate there are no cases of malarial disease in large cities and other localities regarded as non-malarious except such as have been proved by microscopic examination of the blood. And yet just such cases are common in Chicago; and if they are common in Chicago, it would be surprising if they did not occur at all in Milwaukee and Detroit and Cleveland and Buffalo.

It is interesting to recall the fact set forth in "Parkes' Treatise on Hygiene" that the inhabitants of the highly malarious plains of Troy, and of the extensive and pestilential marshy regions of India, are unanimous in testifying that those who drink marshy water are liable to have fevers at all times of the year, and that those who studiously avoid the use of such water are affected, if at all, only during the late summer and autumn months. It is also serviceable to remember that places inherently healthful are dangerous to life by reason of their connection with the breeding places of malaria through rivers which constitute the sources of water supply for their inhabitants. Aitken points out that the Upper Godavary Tract, one of the most virulently malarious regions of India, does not contain one acre of marshy ground; but its people drink the water of the Godavary River which drains more dense forest land than any river in the Empire. Similar illustrations might

be gathered from various parts of our own country. Professor Bemiss, of New Orleans, shows that the poison of malaria may live in water an indefinite and undetermined time, and be conveyed by currents through immense distances, even to remote islands and continents.

If these statements are true, we are warranted in using the facts upon which they are based in elucidating the causes of the prevalence of palustral diseases in Chicago and, possibly, in the other lake cities named. Many a marshy stream empties its waters into those of Lake Michigan. The prevailing current of the lake is northward toward the Straits of Mackinaw. The Calumet River which drains an extensive marshy area in the northwestern part of Indiana and the adjoining portion of Illinois empties its accumulations of organic matter into the lake three or four miles south of the "crib" or opening of the great tunnel which supplies the south division of the city with water. The Chicago River also drains a marshy region and its polluted waters passing into the lake and directed northward, away from the tunnel opening just alluded to, are more likely to affect the sources of supply of other portions of the city. Contrary winds, doubtless, disturb the ordinary direction of diffusion of the marsh poisons through the lake. It is not to be inferred that the water used by the citizens of Chicago is inferior to that of other large cities, for there is abundant evidence that it is not; but it can not be denied that it contains the products of the marshy regions surrounding the head of Lake Michigan. Nor is it to be assumed that every drop, nor even every ton of this water is thus contaminated. It will be sufficient to admit that here and there a citizen gets a dose of the morbid poison in his drink. This is a more rational and satisfying explanation of the midwinter origination of malarial disorders in Chicago and, possibly in other lake cities, than any supposition in favor of "limited foci" of infection which requires us to believe that frozen ground covered with frozen snow can belch forth miasm into an atmosphere whose temperature is below zero, and stock that atmosphere with living malarial organisms.

In the light of these facts, I respectfully invite attention to the following clinical records which represent, in the main, the observations of Dr. Frank Seward Johnson, Dr. Frank Billings and the writer, covering a period of several months.

*Case 1.*—A man, aged 38 years, whose health has been undisturbed for the past fifteen or eighteen years, excepting that now and then he has had vague flitting rheumatoid pains that were strikingly influenced by changes in the weather. He began to be sick in April, 1894. His sickness developed into a typical spleno-myelogenic leukemia. The first blood studies were made for me by Dr. W. A. Evans, Professor of Pathology in the College of Physicians and Surgeons, Dec. 15, 1894, and during the same month the case was used as the subject of a clinical lecture. The case is described in detail in the *Chicago Clinical Review* for January, 1895,—the description including a differential count of the blood corpuscles. The blood contained no malarial organisms. Slides preserved. Again, March 11, 1895, Dr. Evans examined the blood to ascertain the effects of the free administration of Fowler's solution and the glycerite of bone marrow. The number of red corpuscles had increased 17 per cent. and the hemoglobin gain was 8 per cent. The number of leucocytes had increased to a still greater extent. In December the ratio was 1 white to 65 red, and in March it was 1 to 55. The blood contained no protozoa. Slides preserved.

The latter part of March, 1895, the patient was admitted to the Michael Reese Hospital, and his blood was examined

for malarial organisms by Dr. Sievers of that institution. None were found. April 1 a change in attending physicians occurred and the patient passed to the care of Dr. F. S. Johnson, Professor of Pathology in the Chicago Medical College. A few days later Dr. Johnson found the blood teeming with plasmodia,—intra-corpuscular pigmented and unpigmented bodies, and free flagellated forms. There is no question as to the correctness of the original diagnosis. The case is not one of malarial cachexia with ague cake. It is one of leukemia; and the patient became infected with "malaria" after his admission to the hospital. This institution is one of the best constructed and best managed of the kind in Chicago. It is located on clean sandy soil near the lake shore and there are no recent excavations to be found near it.

*Case 2.*—Mrs. L., aged 56 years. Residence Bowen Avenue. Has lived in Chicago eighteen years. She has been an invalid eight years on account of arthritis deformans; and for the past two years has not been off the bedroom floor of her residence. Of late there has not been much suffering but there is almost universal destruction of the joints. There are also extensive cardio-vascular changes. The urine is habitually scanty, the bowels costive, appetite, digestion and general nutrition, fair. January, 1895, was called to see the lady and found her strikingly feeble, anemic, with edematous feet and ankles, and complaining of distress in her stomach. Prescribed without making a systematic examination.

March 24 visited her without being sent for. A couple of days before I had a conversation with a medical friend on the subject of masked malarial intoxication and had become curious after more complete knowledge of my patient's condition. Found her under the care of another physician and treated for "grippe." She was very ill. The attendant consented to have the lady's blood examined. I was informed by the gentleman who made the examination that the blood contained many intra-corpuscular bodies, pigmented and unpigmented, and a few organisms that were free. Nevertheless the patient died of "grippe" a few days later.

*Case 3.*—L. B., aged 6 years. Residence Prairie Avenue near 50th Street. The child was born in Chicago, has never been out of the city, and has been out of the house only two or three times since Christmas, 1894. General health good. Domicile and surroundings wholesome. March 18 the patient developed a fairly typical quotidian intermittent fever. Malarial infection proved. No excavation of recent date found.

*Case 4.*—Miss H., aged 16 (?) has lived in Chicago many years in a good house and neighborhood. No excavations near. April, 1894, she began to be sick gradually with a continued type of fever marked by irregular fluctuations, which was labeled by the attending physician, Dr. Samuel Cole, "typhoid fever with malarial features." The fever continued about four weeks and then, after an interval of normal temperature lasting a few days, there was a relapse. The patient had taken quinin freely from the beginning. Upon the basis of two examinations made by myself during the month of May, 1894, the diagnosis of the family physician was sustained. Later the blood of the patient was examined by Dr. F. S. Johnson and the fact of malarial infection, previously assumed to exist, was demonstrated. Quinin was administered with great freedom by the mouth, rectum and hypodermatic method, and arsenic and iron were also pressed systematically, but without affecting the course of the disease. The patient was seen at this time by Dr. N. S. Davis. Her illness continued over four months, uninfluenced by treatment to an important extent, and finally came to be attended with acute pulmonary tuberculosis. Death occurred five or six weeks later—the blood of the patient crowded with plasmodia to the last. Her sputa had been examined for bacilli repeatedly during the progress of the sickness, but none were found till "between three and five weeks before death."

*Case 5.*—Young lady just arrived in Chicago direct from her home in New York City. Before leaving home she had an alveolar abscess which had been thoroughly drained and which was discharging freely when she arrived in Chicago. She had a chill on the train, and some hours later when examined by Dr. Cole showed a temperature of 103.5 degrees. The abscess cavity was thoroughly and frequently irrigated with antiseptic solutions. Drainage perfect. A second chill occurred that night and the ensuing fever reached 105 degrees. The next morning patient's temperature was normal. Thorough search for pent up pus was made by the consultant, Dr. L. L. McArthur, and none was found. Dr. Cole then examined the patient's blood and found it

stocked with malarial organisms. Quinin, administered freely by the stomach, had the effect of modifying the recurrent paroxysms of fever and of lessening the number of protozoa in the blood. A violent gastro-intestinal catarrh occurred at this time which made it necessary to give the antiperiodic hypodermatically. This was done; but, notwithstanding the administration of 40 to 60 grains daily and the fact that the patient was kept profoundly cinchonized, the chills and fever increased in frequency and severity. Some abscesses occurred in the site of subcutaneous injections. Malarial infection of the blood continued till the death of the patient. It seems to have originated in New York City.

(Cases 6 to 8 inclusive, occurred in the practice of Prof. Frank Billings.)

*Case 6.*—M. W., a boy aged 10 years. Residence Drexel Boulevard. Family history good. The boy has never been seriously sick. At home he uses Waukesha water but at school he drinks hydrant water. About Dec. 1, 1894, the boy, seeming to be quite well, had two primary incisor teeth extracted. Continuous hemorrhage resulted which was checked with difficulty. December 5, epistaxis began which finally required plugging of the anterior and posterior nares for its arrest. Between December 4 and 14, numerous points of subcutaneous hemorrhage appeared, together with a subconjunctival extravasation. The child was now exsanguinated, weak, restless, of normal temperature, and exhibited a pulse rate of 120. Spleen not palpable. Liver area normal. December 14 the blood was found to contain both intra-corpuseular and free, malarial organisms. Quinin and Fowler's solution were prescribed and the patient improved steadily. December 16 the spleen was found to be palpably enlarged and there was a slight rise in temperature. Small nasal hemorrhages occurred on two or three later occasions but the boy was fully restored within a month. The patient was seen in consultation with the family physician, Dr. E. O. F. Roler. The case simulated purpura hemorrhagica and it appears certain that the information furnished by the blood examination resulted in the saving of life.

*Case 7.*—J. O. B., a laborer, aged 49, has lived in Chicago fifteen years and has not been out of the city any important length during this period. Admitted to Mercy Hospital Sept. 30, 1894. Has had irregular bowels all his life, and more or less dyspepsia the last five years. Eight years ago he had severe attacks of biliary colic and four years ago he broke his right leg near the ankle. Some deformity has resulted, the skin covering which is red and scaly. About six months ago he noticed bluish-black discolorations between the knee and ankle, which, subsequently, became yellow and itchy. Still later, similar spots appeared on the thighs, and extended until they discolored the whole integument of the lower extremities. Where he had scratched the skin it had become inflamed, and a sticky discharge issued from it. On admission his liver and spleen were found to be somewhat enlarged; his urine was normal; and the lymphatics of the groins, axillæ and neck were increased in size. His morning temperature ranged from 98 to 99.4 degrees and his evening temperature between 100 to 102.2 degrees. Originally the case was regarded and treated as one of eczema. December 2 a blood examination was made and large numbers of malarial organisms were found, free and intra-corpuseular. Quinin and arsenic were prescribed, together with an occasional purgative; and the patient improved rapidly. He left the hospital, convalescent, Jan. 8, 1895. At that time his spleen was still palpable but much diminished in size. The purpuric eczema was well. On his way home he became chilled and the next day was seized with severe colicky diarrhea which continued till he returned to the hospital, completely exhausted, January 21. At this time the blood examination was negative as to malarial organisms. The patient died three days later. The autopsy, confined to the abdomen, revealed ulcerative enteritis, a chronic splenic tumor and sclerosis of the liver.

*Case 8.*—Mrs. F. S. S., aged 36, formerly lived in the southern part of Indiana and suffered from malarial fevers, but for two years past has lived in Minneapolis, Minn., and has had good health. She still visits her old home occasionally. During the latter part of October, 1894, she was suddenly seized with severe pain in the epigastrium which radiated toward the right hypochondrium and was especially severe in the region of the gall bladder. The pain was attended with nausea and vomiting and was so intense that it required large doses of morphin, hypodermatically, to subdue it. It recurred daily but at irregular hours, for two weeks. It suddenly shifted to the region of the right kidney but contin-

ued with unabated violence at irregular times till about the middle of December. The first diagnosis was biliary colic and the second renal colic. An exploratory operation was under consideration. The urine was scanty and the twenty-four hours' urea was about half the normal quantity; but no abnormal ingredients were present. A blood examination made Jan. 4, 1895, discovered a considerable number of intra-corpuseular malarial parasites. The free use of quinin was attended with immediate improvement and at the end of six weeks the patient returned home entirely recovered. Much of the time consumed in the treatment was required to overcome the effects of the long continued and free use of morphin. Here a correct diagnosis saved the patient from a severe operation.

(Cases 9 to 13, inclusive, occurred in the practice of Dr. F. S. Johnson.)

*Case 9.*—Mrs. F. was seen a week after normal confinement. She had much headache, a little fever and an irregular lochial discharge which was profuse and bloody every afternoon. Pulse 90 to 100 and temperature 99 to 100 degrees. Blood contained many endoglobular and a few free bodies. Under the usual treatment symptoms promptly ceased.

*Case 10.*—March, 1895. Mrs. C., aged 55, has lived in Chicago forty years and in her present home fifteen years; and has not been out of the city in three years. There are no excavations in the neighborhood. The patient was perfectly well till early in January. At that time, upon awakening one morning, she found her feet red, swollen and painful and her left arm and leg numb and weak. The paresthesiæ have continued but have been inconstant as to intensity and location—absent at times and now limited to one side and then to the other. The redness and swelling of the feet disappeared in twenty-four hours to be followed by a crop of raised, infiltrated, tender erythematous spots, varying in size from that of a silver quarter dollar to that of a five cent piece, which lasted several days and left blood stains. Successive crops have appeared at irregular intervals, and the individual spots show all stages of development and decline. Five days after the onset of the sickness the patient developed a tertian intermittent fever; but this has not seemed to make any impression on the rheumatoid phenomena or the erythematous nodes. Spleen enlarged; bowels torpid; tongue coated; skin anemic and sallow. Examination of the blood discovered small endoglobular bodies and large amœboid endoglobular bodies containing pigmented particles in active motion. Under anti-malarial treatment the rheumatoid pains disappeared; the erythematous nodes continued but were lessened in number; but the chills and fever were not benefited. At the end of three weeks of such experience the patient decided to "quit doctoring." A noteworthy feature of the case is the varying persistence of its different features.

*Case 11.*—February, 1895. Mrs. M., aged 27, was chilled by the weather the night she left New York City, and on arriving in Chicago she had high fever, severe headache and general pains. All symptoms except the headache disappeared in two days under the use of salicylate of sodium and a laxative; but the headache persisted. The blood contained many plasmodia. Quinin, grs. x, was administered, and the headache ceased within twenty-four hours. Two days later the patient called attention to a circumscribed edematous redness on the front surface of both ankles and over the left inner malleolus. Treatment continued, and in a day or two the lady was well enough to resume travel. Infection seems to have occurred in New York City.

*Case 12.*—January, 1895. Mrs. M., aged 55, has not been out of the city for many years. General health good. Last two weeks has had headache, backache, post-sternal pain and a little cough, and has been getting pale and weak. Each morning at about 11 o'clock she has slight chilly sensations followed by about two hours of fever and this by sweating. Diagnosis based on blood examination. Anti-malarial treatment was slowly successful.

*Case 13.*—May 2, 1895. Infant born about Nov. 1, 1894. Suckled by a hired nurse. Thrived till it was three months old. Since that time it has been having an irregular diarrhea and has gained none in weight. No fever. On careful inquiry it was learned that the nurse had been ailing a little. An examination of her blood showed malarial infection. Examination of the infant's blood revealed numerous large and a few small endoglobular bodies. The intestinal disturbance abated instantly upon substituting sterilized cow's milk for the nurse's milk, and the blood infection disappeared promptly under the usual treatment.

The foregoing cases have been selected from a total of forty-five which, with very few exceptions, have occurred since November, 1894. Without the coöperation of the gentlemen named I would not had sufficient cases for this communication. The interesting cases occurred in their practice. Those cited have been selected because they present certain striking facts bearing upon the questions of the source of infection, the diagnosis, and the limitations of the curative powers of our best anti-malarial medicines. Of the total number, thirty unquestionably originated in Chicago between December and May and, leaving out two or three, they originated in a choice and densely populated portion of the south division. It is impossible to say how many cases have been overlooked. Blood examination was confined to suspicious or confusing ailments. Similar cases are, doubtless, quite as common in other parts of the city; but I know of no observations which establish the fact. The exact source of infection is a matter of conjecture. There may be those who can conceive of protozoa disporting themselves on the lake shore of Chicago in December or January without a stitch of clothes on, in an atmosphere that is 10 degrees below zero; but it is easier to believe that the malarial organisms, like other protozoa, live in the water and obtain entrance to the human body by being swallowed. This is not intended as a denial of the possibility, nor even of the likelihood, that marsh air may be laden with them, especially the night and early morning air containing an abundance of moisture. Indeed, if it be true, as stated by H. Gilman Thompson, that they have actually been discovered in the air, there is no ground for further controversy. But so far as known every vital phenomenon manifested by these parasites requires the presence of water; and Bartley, of Brooklyn, N. Y., has demonstrated that they exist in the common source of water supply of that city—a fact that is likely to direct investigation into like channels in relation to other cities. The proofs of water infection are quite as strong as those of air infection, and there is not a doubt that impure water is responsible for the occurrence of paludal disease with immensely greater frequency than is generally known. We have been beguiled by the belief that such diseases do not originate in large cities and especially in the dead of winter; but there is good reason to suspect that they are a more common cause of death in these places than has been supposed, and that the "masked" or atypical forms which are very common are rarely identified. As to their rate of prevalence, beyond the primary fact that physicians of active practice meet with one or two cases per week in Chicago we have no knowledge, but we are free to assume that the malarial organism has no better life prospects in the middle of a severe winter than it has at other seasons of the year, and is no more likely to get into the human body. Most of the cases met have been of the "masked" variety, and, from the standpoint of external phenomena, have not been recognizable as examples of malarial infection. Some have been easily identified on the basis of the periodicity of their symptoms—neuralgic or febrile. Cases strongly simulating pernicious anemia, rheumatism, grippe, erythema nodosum, pyemia, puerperal infection, purpura hemorrhagica, biliary and renal colic, chronic eczema and digestive derangements, are herein recorded, in which it would seem impossible to reach

a correct conclusion without a careful examination of the blood. In a few of the cases it appears probable that the demonstrated malarial infection was an incident and not the cause of the various morbid phenomena described.

Examples of a mild grade of temporary infection in which the health of the individual is but little disturbed are very common. In eight cases pulmonary tuberculosis and malarial toxemia co-existed—an impressive fact suggesting the idea that the diminished powers of resistance occasioned by one, predisposes to the other. In less than half the number a history of periodicity was elicited, but in most of these it required close questioning and observation to do so. The absence or presence of this feature is not safe ground for differential diagnosis. Distinction must be made between true periodicity and the erratic appearance and disappearance of symptoms or of fluctuations in their severity. The entire absence of fever—a characteristic of many cases—would be enough to obviate suspicion on the part of city doctors, especially in the winter season of northern latitudes, that the case in hand may be one of paludal intoxication. Nor is the therapeutic test a reliable guide to diagnosis. The failure of quinin to arrest febrile or other symptoms of disease is considered by many a demonstration that such disease is non-malarial. This assumption is not correct. A patient whose blood is teeming with hematozoa may be profoundly cinchonized for weeks and then die with an undiminished number of parasites in his circulation. In other cases, as every one knows, the medicine is instantly efficacious. These observations strongly support the conclusions of Golgi, Baccelli and others that under the one name are included separate and distinct varieties of microorganism. Quinin causes some symptoms to disappear while others persist; and those showing periodicity may be the ones to persist. Moreover, blood infection may continue after objective phenomena have ceased, but this is not usual. It is quite plain therefore that malarial disorders are of common occurrence in which it is impossible to say with any certainty of correctness, either upon the basis of the external phenomena or upon that of the action of quinin, whether or not the case in hand is of malarial origin and nature.

The active prevalence of such disorders in a city not known as a breeding place of their specific cause, and the facility with which they may be confounded with other kinds of disease, warrant the suspicion that in all large cities not more favorably situated, thousands of cases occur every year and escape recognition. In this connection some pointed questions can be asked as to the soundness of the prevailing opinions concerning the incubative period of these disorders. The duration of this period as stated by authoritative writers is extremely indefinite. It varies between a few minutes and several years. If the meaning of the term is limited to the time intervening between the reception of the hematozoon and the outbreak of a periodical fever, the indefiniteness of statement referred to is fully warranted; for, inasmuch as no outbreak of fever may occur at all, the patient may die while the germ is still sluggishly incubating. Conceive, if you can, of an infection of the human blood breeding and destroying for months or years before it makes its presence known. Name, if you can, any other infection that behaves in this manner. Yet this is the teaching of the day. Flint says that the incu-

bative period may last as long as four years, and W. H. Daly in a recent essay quotes an unnamed writer as saying that it may last seventeen years! Now is there any proof whatever that any such thing ever happened or is possible? It is said by writers—by Thompson in "An American Text-book of the Theory and Practice of Medicine," for example, that during the incubative period the patient may be in comparative health. Who knows this to be true and how did he learn it? Who has ever known of a case of demonstrated malarial infection lasting thirty days during which time the patient was in undisturbed health? It is not a question of opinion but a question of fact. Who knows?

It is well known that there are great differences between individuals in respect to the quantity of infectious matter required to make them sick. It is also true, as I have witnessed twice within a month, that a child or an adult may show a few malarial organisms in the blood to-day and not one a few days later. And this, without a dose of medicine. At the time of infection there were no evidences of sickness—certainly none so distinctly marked as to be recognizable as elements of a fixed disease. But suppose the parasites had triumphed over the blood corpuscles and feeding upon the hemoglobin, and multiplying, how many years would it take the man to discover that something was wrong? In view of what is known of water infection and suspected in relation to ice, milk and food infection; in view of the activity with which malarial disorders are known to originate in Chicago and reasonably suspected of originating in other large cities, is any one willing to stand before this body and say that malaria can incubate seventeen years, or four years, or three months, without showing any results? Suppose a citizen had visited a malarious region in the South for a few days or weeks a couple of years ago and returned to Chicago in undisturbed health; suppose he continued in perfect health till last December and then came down with a malarial fever; is that proof that he got the infection in the South? By no means. During the same period of time probably thousands of citizens who had not been out of the city at all were similarly taken sick. Yet this is the kind of evidence—utterly and absolutely worthless as it is—upon which the incubative period of malarial disorders is estimated. In the light of the revelations of Laveran we must, till reasonable proof to the contrary is furnished, regard every case of prolonged "latent" infection as an example where the individual did not get infected when he had a good chance, but did get infected in a locality that is not known to be, and yet is, a breeding place of malarial diseases.

The same considerations must be applied to the elucidation of the question of relapses. A person who has had intermittent fever and recovered perfectly may exhibit in the diseases of later life an impress of periodicity without having at the time any malarial infection whatever. In recurrent true malarial fevers it may not be easy to differentiate between relapses and new infections; but we may investigate and eventually be able to answer the question. Suppose a citizen of Chicago had ague, recovered, remained in perfect health a year and then had another attack of ague; is this a relapse? The affirmative would represent prevailing opinion, but is there any proof that prevailing opinion is correct? If the same person had had two attacks of pneumonia

or typhoid fever a year apart, who would designate the second one a "relapse?" Nobody. There is not a vestige of proof, so far as I know, that a person ever had continuous malarial infection a year without being sick in some way. If by the term "relapse," is meant repeated outbreaks of fever during the course of continuous infection—the patient being sick with other derangements caused by the infection every day of the time—the inference is different from that given to it in relation to other kinds of disease. All our literature on the etiology of malarial diseases must be revised and put in accord with existing facts. I offer no apology for discoursing upon a subject with which many of you are vastly more familiar than myself; for familiarity breeds indifference, lack of thoroughness and a thoughtless readiness to take things for granted, and it needs to be made to stop and think now and then. The fact that the germs of malaria are often conveyed into the body by other media than the air and that in a vast but undetermined percentage of cases infection is preventable, is one of the most important and imperious before us to-day. It makes the duty of the doctor plain. We grow enthusiastic in contemplating the possibilities of the antitoxins, and we take off our hats to the great army of investigators who, despite the opposition of well meaning philanthropists, "will persist in destroying a few dogs and guinea pigs in order that they may teach us how to save babies," by throttling infection the instant it invades the human sanctuary; but still, after all, prevention is a still higher aim, and it is the chief glory of our profession that its best minds and purest hearts are ceaselessly active in this direction.

#### ADDRESS.

*Before the Graduating Class of the Wisconsin College of Physicians and Surgeons, April 16, 1895.*

BY U. O. B. WINGATE, M.D.

PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM AND HYGIENE.  
MILWAUKEE.

It has sometimes seemed to me that an address on occasions like this, smacked somewhat like a dish of dessert at the end of a banquet, when every one had partaken of more than enough.

I am sure that the students in the college have had their fill; I can not conceive that the Faculty are hungry for any words from one of their number; and I have grave doubts about any of the friends present being in possession of a keen relish for anything oratorical at this time. However, we seem to be victims of custom's decree, but I promise not to weary you long.

The Wisconsin College of Physicians and Surgeons has completed the second year's work of its existence, a work that speaks for itself and needs no encomiums from me. It prides itself on having earnest, faithful and conscientious teachers, students in liberal numbers, zealous in the prosecution of their studies, and it congratulates itself on taking a position in the front ranks among the younger members of American Medical Colleges. It is the purpose of its Board of Directors and Faculty to maintain the stand it has taken, to advance from year to year, and to convince the public, and the medical world as well, by its works alone. It proposes to stand on its own foundation which has been carefully constructed, and it has no fears about its firm and lasting superstructure.

To lay such a foundation and build such a structure thereon, means much hard and self-sacrificing labor, but its promoters have practiced their profession long enough to fully realize this, and they are imbued with a spirit of enterprise fully adequate to the undertaking, and feel confident that the results of such efforts will merit the commendation of a grateful public.

The great State of Wisconsin with its 2,000,000 population and rapidly increasing growth will never fail to welcome educational institutions that have engraved on their banner, "a higher scientific education," and an institution with such ideals, with a firm and steadfast purpose of its governing body, can not fail to meet with the popular approbation of our best citizens.

Gentlemen of the graduating class: It becomes my pleasant duty on behalf of the Faculty of this College, to bid you a cordial welcome into the ranks of one of the noblest, as well as one of the most ancient, of the professions that have been vouchsafed to man. Your first duty, then, is to always keep its sacred precepts before you and forever endeavor, to the utmost of your ability, to maintain its dignified and venerable character. This duty well performed, all other appropriate things will follow in proper order.

I should, perhaps, be unfaithful to my methods of teaching if I did not give you, at this time, a few words of warning relative to your own physical and mental welfare in undertaking the arduous labors inseparable from a physician's life. Statistics show that among all professional lives that of the physician is the shortest, and the reason for this physicians know full well. The demands upon your strength, both mental and physical, are far greater than in any other calling with which I am acquainted, but remember that it is not the hard mental or physical labor that kills, but the friction caused by irregular hours of rest and food, worry, disappointment in life, and the constant strain on the nervous system, so hard to regulate in the practice of medicine. Permit me, then, to counsel you to early attain as regular habits as possible, and demand for yourselves sufficient rest, else you will find yourself, all too soon, in the position of "the blind leading the blind."

The nerve force generated in your systems, you know full well, is only capable of accomplishing about so much, and what is expended in one direction will fall short in proportion in another direction. This was never better illustrated than in our modern times when we see so many falling by the wayside from troubles resulting from the strain, worry, and irregularities of the times in which we live, and you, as counselors of the people's health, should be the first to recognize the danger.

Let me counsel you to observe, with a scientific eye, what has been termed "the physical stigmata of degeneracy" of the present time, so well illustrated by the flood of printed matter that robs students of food and peace of mind. I refer more especially to that literature that treats of sudden reforms and pseudo-organized methods promulgated by pseudo-organized individuals "scarce half made up," and the idle clatter they make from time to time through the agency of printer's ink. You will find this, more or less, in all of the literature of the day, in the morning, evening, and Sunday papers, magazines,

books, medical periodicals, scientific journals, in fact in all literature. Permit me to counsel you to judge them always from strictly anatomic, physiologic and pathologic grounds, aided by chemistry, and such other recognized sciences as you can depend upon. Your usefulness in life will depend largely upon the care and discrimination with which you treat and consider these matters.

Let me warn you that intelligent people are fast learning to recognize that the physician who boasts of treating thirty or forty patients in a period when he should treat but ten, even if his boast be true, is not doing his full duty to those who have intrusted their lives to his care, any more than an artisan can rush through with a piece of work, and do it properly in half the time required to do it well. The older I grow and the more I observe, convinces me that the ideal successful life is not attained by a short, spasmodic though brilliant career, so much as by the long steady pull and the attainment of a full rounded out existence intended by the Creator of our being. To attain this, one must begin early and learn the great lesson of the earliest writers, so aptly expressed by Pope: "Know thyself; presume not God to scan. The proper study of mankind is man." Having fortified yourself with a complete knowledge and absolute control of self, you will be enabled to go forth and exercise your important function in life. Gentlemen, this is the first principle! A college life is only intended, indeed it can only expect, to teach first principles. Your diploma is only an emblem of first principles and represents but an entering wedge into future knowledge. In other words, so often repeated, it is but the introduction into student life.

The profession of medicine is a progressive work. You have to deal with human life that is of itself progressive, evolving, revolving. There is no profession that demands a more discriminating conservatism, and at the same time wholesome progressiveness so much as the one you are entering. You must always maintain a strong, healthy, physical, mental, and moral character, for upon your efforts may depend not only the life and happiness of a family, but the life, prosperity, and greatness of a nation—a world.

Whatever your impressions may have been concerning your college course, there is one thing that now must forever stand foremost in your mind's eye, that of responsibility. Heretofore you have left responsibility to your teachers; now you enter a realm where you must share that responsibility yourselves.

It is interesting to one who has been a student and teacher in a medical college, to watch the changes that take place in a medical student from the time he enters college to the time of his graduation, providing he proves himself entitled to graduation. I have passed through all of their gradations. Contemplate the green, hilarious first-year man. Inclined to destroy all with which he comes in contact. Seats in the college are marred and broken, together with windows, doors, blackboards, and it seems to the teacher that his whole intent in life is destruction. He may, under certain circumstances, if there are no other provisions, even rob graveyards of their legitimate occupants. But observe the change that comes over him in his third and fourth year of study, under conscientious and faithful preceptorship; how he changes his destructive characteristics. He be-

comes an interesting, pleasant personality to his preceptor. He is earnest and painstaking in all that pertains to reality in life. He may caution the students in the first and second years against their destructive proclivities, and tell them they ought not to do so. He is inclined to treat his preceptor with a higher degree of respect than ever before. He takes more interest during the lecture hours, and as he advances to the final examination, before he enters the sacred duties of the medical profession for life, he may show to his preceptor that he still proposes to rob graveyards, but in a far different sense from that in which he began his work. He proposes to snatch from the grave, so far as the armamentarium of a medical science will permit, the devoted husband and father, the tender wife and mother, the lovely bud of childhood, the brother, the sister, the all that is sacred to the human heart. He does not hesitate to use his anatomic knowledge for the benefit of justice in disclosing crime and wickedness in the dissecting or autopsy room and on the witness stand, regardless of the unjust criticism that frequently follows. Gentlemen, you must be patient. It is a part of your education to bear the darts that fly thick and fast, at times, about you. You must also bear with the inconsistencies of life, the deprivations of comfort and happiness, and seek satisfaction in the inward feeling, which you must try to develop at all times, that you have done your duty. Duty well performed is always sure of its reward, and the science of medicine, your chosen profession, a science that is linked with all other true sciences has nothing to fear, and you, as its true disciples, I am confident will never flinch from duty.

Remember, that while the practice of your profession is markedly different from what it was a century ago, your duties are none the less sacred nor your responsibilities none the less heavy; neither will they be while love kindles the fire of the noblest aspirations of human life, thought clothed with divine majesty scans the pages of the history of life and death, and science with its piercing light penetrates into the darkness of the unknown and reveals the truth.

## LECTURES.

### LECTURES ON INTRACRANIAL SURGERY.

IX.—THE OPERATIVE TREATMENT OF IDIOCY.

BY EMORY LANPHEAR, M.D., PH.D.

ST. LOUIS, MO.

It is with a feeling of diffidence that I take up the subject of the surgical treatment of idiocy, for I am uncertain as to the advisability of such measures; yet as medical literature, some two years ago, was glowing with accounts of wonderful results obtained, and periodicals of to-day contain articles condemning the plan as unscientific and valueless, the subject deserves more than passing notice.

#### HISTORY OF THE OPERATION.

The proposition to relieve idiocy by operation originated in America. Dr. William Fuller, of Grand Rapids, Mich., who was at the time Professor of Anatomy in the Medical College of Montreal, Canada, at a meeting of the Montreal Medical Society, in 1878, read a paper upon the subject, with the report of a case operated upon by himself. Moreover, Louis

Bauer, M.D., M.R.C.S., Eng., the distinguished Honorary Professor of Surgery in the Marion Sims College of Medicine, of St. Louis, operated for microcephalus at the St. Louis City Hospital in 1871. The microcephalus was of the acquired variety, accompanied by petit-mal, as well as the convulsive form of epilepsy (sometimes as many as twenty spasms in twenty-four hours). Dr. Bauer claimed that the cerebral trouble was due to premature ossification of the cranial sutures and so removed a large segment of the skull for the purpose of giving space for growth of brain. Recovery from the operation was speedy, and the boy disappeared. Five years later the patient when seen by Dr. Bauer was so changed in physical and intellectual condition as not to be recognized. He is now the proprietor of a general store in Arkansas and is a successful business man. So far as I can learn this was the first operation ever made for microcephalus; and although the object was relief from epileptic seizures, and not for the cure of idiocy, it can scarcely be denied that to St. Louis belongs priority in operation for microcephalia.

Scarcely any attention was paid to the essay of Dr. Fuller, except a few condemnatory comments and the subject remained in quiescence until 1890, when Lannelongue, of Paris, startled the medical world by boldly declaring that for the unfortunate idiot relief had been found in operation, as demonstrated in a large number of cases. Following the publication of his report many operators in Europe and America hastened to open the skulls of microcephalics and to rush into print almost before the wounds were healed. Happily the "epidemic" is over and we can now view the results dispassionately. As no recent articles have been published giving reports of progress, I shall base my remarks chiefly upon my own cases.

My experimental work in the operative treatment of idiocy has consisted of twelve operations, covering all classes of idiots in which there is even a faint possibility for improvement. While my cases are, perhaps, more numerous than any other American operator's, they do not approach Lannelongue's reports either in number or brilliant results; at the same time, the cases are not, like his, limited to microcephaly alone, and hence are perhaps of more value in a general way.

#### VARIETIES OF IDIOCY.

All idiots may be classed under the heads: 1, congenital; 2, microcephalic; 3, eclamptic; 4, epileptic; 5, hydrocephalic; 6, paralytic; 7, cretinic; 8, traumatic; 9, inflammatory. They all have something in common; thus, in addition to the mental trouble many are deaf mutes, or are blind, and anesthesia as well as anosmia may be present; some learn to walk late, or not at all, and most of them have a shambling gait, which in the cases of microcephalia, closely resembles that of the anthropoid apes; a general restlessness, vacant stare, thick and everted lips, etc. Altogether the proper classification is rather difficult, but the following distinctions should be noted:

1. In congenital, or genetous idiocy, the subject is often dwarfish; deformities are numerous, particularly a high vaulted palate, with teeth irregular and decayed; deficient growth of nails; eyes rolling or squinting; mental condition a total blank.

2. In microcephalic idiocy the head is small, but the physical defects are less marked than in the genetous form; there is some tendency to learn some

things, and as the subjects grow older they improve under training and present more physical and mental energy than is found in other classes. There are two varieties: *a*, congenital, in which the mental weakness is due to agenesis of brain structure, the synostosis being secondary to the cerebral defect; *b*, acquired, in which the brain has begun development but the bones, for some reason, too suddenly unite and cease to grow, with a consequent cessation of cerebral development or even retrogression, until the child from being more or less intelligent becomes a complete idiot.

3. Eclamptic idiocy succeeds infantile convulsions. As the child develops, although there may be little trouble with motion or sensation, it is found that it is capable of acquiring very little education.

4. In the epileptic form the child may have been primarily well-equipped mentally, but after the destructive paroxysms appear there is more or less marked deterioration; later on, if anything be learned in the interval between epileptic seizures, a new attack erases it from the memory. Such patients are apt to appear to be on the boundary between imbecility and insanity.

5. Hydrocephalic idiots present the usual signs of hydrocephalus. Some cases are due to porencephalia (ventricular dropsy, with more or less complete absence of the upper part of the hemispheres) while others depend upon dropsy of the arachnoid. Albers, of Bonn, makes this distinction: mental obtuseness and paralysis indicate effusion into the ventricles; while restlessness and mental derangement point to fluid in the sac of the arachnoid.

6. In paralytic idiocy the patients are tractable and docile, but the same destructive lesion that renders the patients completely paralyzed affects the centers of intellect—hence they are hopeless.

7. Cretinism is a form of idiocy quite rare in America, but very abundant in certain parts of the world (Switzerland especially) where the condition of soil, air, water, etc., give origin to it. After the sixth month the condition is readily recognizable: bodily development is very slow; the baby, though weak, is remarkably fat and appears swollen; the skin is often dusky, or yellow, but sometimes natural in color; the head large, and fontanelles wide, with sutures sometimes disjoined; the expression stupid, appetite voracious, belly swollen immensely, neck thick, but the extremities attenuated. Later, teething is not completed for many years, but is accompanied with offensive salivation and convulsions; the child does not learn to stand before the sixth year; about the seventh year it begins to make a few articulate sounds in a hoarse but shrill voice, with great difficulty in speaking. The disproportionately large feet, attenuated legs, swollen belly, cumbrously large head drooping over, an illy developed thorax—these are unmistakable.

8. Traumatic idiocy usually may be traced to injuries by attempts at abortion or by use of obstetrical forceps. In degree the mental impairment may be severe or trifling, and in continuance either temporary or permanent.

9. Inflammatory idiocy is that form which follows attacks of so-called "brain fever"—meningitis with more or less exudate.

Low grade imbeciles differ very little from the congenital idiots, except in extent of mental development; they think, feel and speak, and can be taught some simple things.

#### WHEN OPERATION MAY BE DONE.

The earlier in life the operation can be done the better; certainly it is not probable that any benefit can be expected in idiots of more than 8 or 9 years of age. Nor are all idiots fit subjects for this experimental operation. Congenital idiocy may possibly be improved through the increased flow of blood set up by the operation. Microcephalic idiocy offers decidedly the best field, especially in the form which Binnie (*Kansas City Medical Index*, May, 1891) has termed "acquired microcephalus." It is scarcely justifiable in pure eclamptic idiocy. In epileptic idiocy there may be a chance for improvement in some cases. In hydrocephalic idiocy, tapping the ventricles and establishing permanent drainage may perhaps do good in the first group; but better results are to be anticipated in the second class (arachnoid-ea hydrops). In traumatic idiocy, nearly as much can be expected as in traumatic epilepsy or insanity. In inflammatory idiocy, operation is certainly inadvisable. No operation is justifiable in cretinism; the prospects of improvement from the use of thyroid extract seem to be very bright indeed; and this line of treatment should be further investigated.

#### PRELIMINARY TREATMENT.

On the day before the operation the patient is chloroformed, and the head carefully shaved. The whole scalp is scrubbed thoroughly with soap and water; dried carefully, washed with sulphuric ether; again subjected to soap and water, and finally doused with a solution of bichlorid of mercury of the strength of 1 to 1000. The head is then enveloped in bichlorid gauze, held in place by a bandage.

#### PREPARATION FOR OPERATION.

The child being put completely under the influence of chloroform (ether never being employed, since it causes too much congestion of the field of operation), the dressings are removed from the head and the scalp scrubbed with a saturated solution of permanganate of potassium, followed by a saturated solution of oxalic acid; it is then rinsed with bichlorid solution, and the head wrapped in towels wrung from the same. This is the last use of any antiseptic solution in the operation, as plain hot water, previously boiled, must be employed for irrigation and for wetting the "sponges," which are not sponges at all, but balls of iodoform gauze which will be thrown away as soon as used. Every instrument must have been boiled for twenty minutes immediately before using, and the hands of operator and assistant must be carefully disinfected by washing in the solutions used upon the head. These apparently trivial details in asepsis may seem superfluous to those who have seen excellent results in the work of men who are absolutely *dirty* in their methods; but if a surgeon expects to maintain a low mortality rate, especially in cerebral surgery, the closest attention must be paid to the most minute points of possible contamination. Being, therefore, certain that everything is in perfect readiness, the preliminary suturing may be done. Beginning at the median line, just at the margin of the hairy scalp, a suture of strong silk is introduced; stitches of about three-fourths of an inch being taken, the line of suture is carried backward to a point near the occipital protuberance, then turned toward the side and brought down to near the level of the ear, and thence carried forward to within some two inches of the point of beginning. By this prelimi-

nary stitching, the bleeding may be controlled far better than by an Esmarch bandage passed around the head. This step is perhaps the most important in the whole operation, because every drachm of blood lost will weigh against the recovery of the little patient. Children stand the loss of blood poorly, and I am sure that many cases have been lost on account of want of attention to hemorrhage. The condition which is called "shock," so frequently met after operations on the head, may, in most cases, be ascribed to loss of blood.

#### THE OPERATION.

The field of operation having been thus entirely surrounded, a large flap in the shape of a horseshoe, with its base forward, is quickly cut (with a single stroke of the scalpel clear to the bone) and raised. In the flap the pericranium is included; at the sutures there are some adhesions, but these are readily freed by the handle of the knife. The bleeding points, few in number, are seized with hemostatic forceps, and the flap enveloped in bichlorid gauze wrung out of hot water. Hemorrhage having been completely checked, an attempt should be made to go through the skull with the sharp gouge, which is preferable to the mallet and chisel and to the trephine whenever

the bone is soft and thin enough to permit. I have seen disastrous results from the use of the trephine, and have myself lost one patient under circumstances that seem to point to the use of the mallet and chisel. But if the bone is too hard for the gouge, a half-inch trephine is brought into use, and a button removed in the usual manner. The opening must now be enlarged. For the purpose, Parkhill's new craniotomy forceps answer admirably, as do also Keen's. The opening is, by means of these forceps, rapidly extended forward until it measures at least four or five inches in length and from an inch and a half to two and a half in width, its anterior margin being as near as possible to the border of the hairy scalp; it thus exposes a considerable portion of the frontal convolutions, as well as a part of the motor area. If one is very careful, there should be no wounding of the vessels of the meninges, but if inadvertently injured, a needle, armed with fine juniper-oil catgut, must be inserted through the dura, carried under the vessel, and brought out a line or more beyond, and the gut tied—thus ligating *en masse*. The edges of the hole are now smoothed by a small rougeur, and the fragments of bone carefully washed away. The appearance of the wound is now as shown in illustration.

At this point the sutures surrounding the site of operation are removed; and bleeding vessels caught and tied. While the wound is being irrigated the flap is uncovered and washed. The whole field is now dried and covered with iodoform; the flap replaced and stitched with a continuous suture of medium size. A few strands of gut are inserted at the lower angle of the wound and pushed well up beneath the flap to insure drainage. The enveloping towels are now removed, the scalp washed and dried, the wound hidden by powdered iodoform, and dressed by using a considerable quantity of iodoform gauze next to the head, then a larger quantity of bichlorid gauze, then cotton and a bandage. As thus performed, the operation can be completed in less than thirty-five minutes.

#### AFTER TREATMENT.

The child is now put to bed and treated as if suffering from any other wound. Usually there is very little trouble after the operation. Most of the cases I have operated on have been able to sit up in bed the following day, and some have gone on in their little play in a few hours, as if nothing had happened. This first dressing is allowed to remain until the seventh or eighth day, unless some special reason exists for its earlier removal. At the end of a week, primary union will be found to have occurred, and the dressings are to be replaced by a close-fitting head-dress of bichlorid gauze, cotton and bandage, which is to remain until the time for the second operation. This will be in two or three weeks, according to the condition of the patient. The child is then chloroformed, the dressings removed, and the scalp again shaved and washed with soap and water, ether and bichlorid solution. It is not, however, necessary to do this on the day preceding the operation, as in the first instance, because the scalp is still in an aseptic condition from the first operation.

The second operation is precisely similar to the first, save that it is made on the opposite side of the head. One week after the operation, if everything has gone well, the permanent dressing may be put on and the child allowed to go out; so that the total period of stay in the hospital need not exceed four weeks, and one may be able to cut it down to three.

It will be noticed that my mode of treating these cases by a large oval opening, differs considerably from Lannelongue's operation, which has been practiced by most American surgeons, notably Keen and Wyeth, and which consists of a large, long flap made in the shape of a U, V, or T, the dura being opened only when there are evidences of pachymeningitis; but I have seen the opening close up within a few weeks in the Lannelongue operation, with return of all the bad symptoms for which the craniotomy had been made. In none of my cases has this occurred, and I believe the larger opening affords more room for improvement.

Consideration of the very important question of "What Are the Results?" with a report of cases, must be deferred until the next lecture.

(To be continued.)

**Malpighi's Memory in Japan.**—A recent number of the *Sei-I-Kwai* medical journal records a bicentenary celebration held by the Tokya Microscopical Society in honor of Marcella Malpighi, the anatomist of Bologna, who was the first to describe the minute anatomy of the kidneys and other organs in 1694.

## ORIGINAL ARTICLES.

## THE PROCESS OF FORCED DILATATION WITH IMPACTED NEBULA.

AUXILIARY TO THE MEDICAL AND SURGICAL TREATMENT  
OF THE EARS, NOSE, THROAT AND CHEST, WITH  
ILLUSTRATIONS OF PORTABLE APPARATUS. SOME  
SUGGESTION TO GENERAL PRACTITIONERS  
AS TO THE SELECTION OF MEDICINAL  
AGENTS AND AS TO MEASURES  
FOR CONTROLLING PULMO-  
NARY DISEASES.

BY GEORGE F. HAWLEY, M.D.  
CHICAGO.

Through new discoveries and improved methods for preventing diseases and restoring health, the general and special practice of medicine and surgery is gradually becoming a practical if not a positive science.

While marked progress has been made all along the lines of general, and in some lines of special practice, it is a lamentable fact that there have been but few improvements in the facilities, and none in the methods, of treating diseases of the air passages locally, for the past ten or fifteen years, until the discovery of a new process for preparing and administering impacted nebula by forced dilatation, and the invention of an instrument for accomplishing the same. With the exception of this discovery and invention, the means and measures employed at the present time in the local treatment of the air passages are identical with those of the past.

In a former paper entitled, "A New Apparatus," contributed to and published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION May 12, 1894, page 702, the construction and operation of the Standard Dilator, the process of forced dilatation and the methods of using the same in the treatment of the ears, nose, throat and chest was illustrated and fully described. Judging from the number of physicians who have asked for additional information, both in person and by letter; also from the fact that some have, on the advice of manufacturers or dealers, attempted to carry out this process by the use of nebulizing inhalers or other similar but improperly constructed apparatus, I conclude that neither the construction of the apparatus nor the principles underlying the process of forced dilatation with impacted nebula, nor the motive that prompted the writing of the paper is generally understood. Actuated solely by a desire to benefit the profession, and to add my mite to the sum total of medical science, I accepted the opportunity of being the first to call the attention of physicians to this discovery and invention through the medical press, an opportunity which I am persuaded but few of my medical brothers would have declined under similar circumstances. I was not then, am not now, and never was financially interested or benefited by the manufacturing or sale of any instrument or apparatus for physicians' use.

Manufacturers and dealers have at their own suggestion conferred upon me the empty honor of naming after me, instruments and apparatuses similar in construction to those used in my practice. That, and the gratification of having aided in pioneering their use, is all the remuneration that I ever received or would have accepted.

The purpose of this paper is to call attention to

the Hand Dilator and a recently perfected portable apparatus which constitutes a complete outfit to be used in the process of preparing and administering impacted nebula by forced dilatation. In addition to being well adapted to the scientific and expeditious treatment of the ears, nose, throat and upper air passages, it brings the lungs and deeper air passages completely under the control of the physician.

The apparatus herewith illustrated consists of a receiver of eight gallons capacity, with pump, regulating meter valve, conducting hose, and cut-off, all combined. As the complete outfit weighs less than eighteen pounds, its portability adapts it to use at the bedside of the patient in home, sanitarium or hospital. It is equally well adapted to the use of the general practitioner in the treatment of office patients.

The Hand Dilator is attached to the cut-off and held in the hand in the same manner that sprays are attached and held. It consists of a strong 2 ounce glass jar surmounted by a dome to which the nasal, the laryngeal, or pharyngeal tubes or nozzles can be adjusted or changed from one to another instantly.

The percentage of the medicament in the impacted nebula can be regulated from the minimum to the maximum strength instantly or gradually by turning a thumb-screw. This obviates the preparing or keeping solutions of different percentages of strength.

The Hand Dilator is as efficient as the Standard Dilator in the preparation and administration of any selected medicament into any air passage or cavity without liability of lacerating tissue, or causing hemorrhage.

As impacted nebula is practically dry, it can be administered into the lungs without injury or undue irritation. Into the Eustachian canals and tympanic cavities through the nares, with or without the use of a catheter; into the nose or throat without flooding the cavities with a disagreeable and disgusting excess of aqueous or oily solution, which the patient

finds it necessary to immediately eject by hawking, spitting, and blowing the nose.

Although impacted nebula is practically dry, its administration by forced dilatation will remove deposits of tenacious mucus or incrustation from the nose or throat quicker and easier than the same can be removed by liquid sprays.

For fully illustrated instruction in the methods of administering, and the physiologic and therapeutic difference between forced dilatation, inhalation, Politzerization and catheterization, see my paper published May 12, 1894. The method of using the Standard Dilator or the Hand Dilators is essentially the same.

Notwithstanding exact nicety is required in all the details of preparing and administering any selected medicament by this process and apparatus, it is nevertheless confidently expected that its adoption and use will inaugurate an era of improvement in this particular branch of practice, and lead to the discovery of other means and measures whereby cures may be effected in the upper air passages without a resort to the supplementary surgical interference so frequently found to be required during the past, while by its judicious use those afflicted with pulmonary diseases may be saved the expense and fatigue of long journeys in wandering over the earth in an effort to prolong life through climatic influence.

While the propriety of a change of climate as an expedient may for obvious reasons be questioned, the free, full and unobstructed breathing of air is acknowledged to be an absolute necessity for the preservation of health and life, for the well-known reason that it is through the respiratory function only that oxygen can enter the blood and carbon dioxide can be eliminated. The importance of oxidation in the chemic and physiologic processes by which the food stuffs are changed into molecules of bioplasm for the formation of the white blood corpuscles is well known. It is also well known that it is through the aid of the oxygen carrying hemoglobin of the blood that the molecules of bioplasm constituting the white blood corpuscles are elaborated in the processes of assimilation, through which tissue metamorphosis is brought about. Thus a partial equilibrium in supply and waste is maintained.

The heat resulting from respiratory combustion is dissipated in part through physiologic evaporation. The remainder being stored as force, in ganglionic nerve centers, to be expended as required.

Although respiration is such an important function there are but few persons who breathe enough air, none too much and many not enough.

There are persons who have no control over their respiratory apparatus. They can not expand or contract their chest or take a long, full, deep breath. They breathe but little air and as a matter of course the purer it is the better for them. Such persons can not practice lung gymnastics; they do not know how, and many of them can not be taught. Forced dilatation is their only help, for by it they can be made to breathe full and free. To the very feeble, forced dilatation affords all the benefits of lung gymnastics and outdoor exercise without fatiguing exertion. It is efficient in developing the chest of the young or middle-aged and for maintaining the lung capacity of those who are old or exhausted by mental or physical work. It affords relief to those whose respirations are impeded by atmospheric or other influences;

influenza, hay fever and asthma being extreme examples.

The prevalence of milder and more obscure forms of impeded or slightly obstructed respiration leads to the conclusion that there is some peculiar property in the air of every locality which, during certain seasons of the year, affects the air passages of many, while others are exempt. To this, or to some other equally obscure and unpreventable cause, may be traced many maladies which are primarily initiated in the air passages, and which on account of obscure and misleading indications are neglected during the early stages. The affection results in varying degrees of stenosis or occlusion of the upper or deeper air passages, or some of them. The objective and subjective symptoms being entirely different from those attending recognized and well-defined cases of coryza, influenza, hay fever or spasmodic asthma, not only in the absence of cough, excessive secretion, congestion or inflammation, but in the fact that such patients rarely complain of difficult breathing. The subjective indications being few and the objective obscure, the physician is often misled through the patients declaring that their lungs are good and that "there never was a case of consumption in their family." They simply complain of "that tired feeling" and from that alone many of them seek relief. Some of them before, others after, and not until after, swallowing the contents of several bottles of a widely advertised nostrum find their way to the family physician or general practitioner, who after a casual examination generally prescribes tonics and rest. But "that tired feeling," complicated by other evidences of decline, often continues until the patient is pronounced incurable and advised to seek relief in a change of climate. But as there is no climate or locality where all are absolutely free from obstructed or restricted respiration, there is none where mankind can be free from the resulting sub-oxidation, mal-nutrition, and all the evils which that condition implies.

The fact that there are many persons who do not breathe through both nostrils, and some who can not nor have not breathed well through either for years, may be mentioned as an example of obstructed respiration, and of which many are unconscious until their attention is called to it. This fact leads us to conclude that if the lungs of such patients were as completely under their observation as is the nose, they could be made to realize a similar condition of stenosis or occlusion in the deeper air passages.

General practitioners will, I trust, pardon me for suggesting the necessity for a thorough examination of the chest in all cases of illness. For the reason that the important part which the lung plays in the elimination of the waste products, water and carbonic acid, can not be over-estimated. A quantitative and qualitative analysis of the respiratory exhalations from any one suffering with any form or degree of illness will disclose the fact that the equilibrium of supply and waste through respiration is not maintained, due to obstructed functional activity on the part of the lungs. It therefore follows that a restoration to the normal capacity, and to functional activity, and the consequent restoration of an equilibrium in supply and waste, through respiration, is an important factor in the restoration and preservation of the health.

While the pharmacist and instrument-makers have

placed agents in the hands of physicians to control most maladies, either by therapeutic measures or surgical procedures, no agent was at hand by which diseases of the deeper air passages or those resulting from and continuing on account of obstructed respiration could be controlled, until the discovery of the process of forced dilatation with impacted nebula and the invention of the dilator.

After nearly two years' experience with a four-bottle set of the Standard Dilators, and a set of Hand Dilators, I now feel justified in attributing to their use as auxiliary to other medical and surgical means and measures, a more rapid and constant improvement in all cases treated, and the recovery of several persons in the first and second stages of pulmonary tuberculosis, others of long-standing asthma, others of impaired hearing from ankylosed ossicles, hypertrophied membranes and thickened and retracted drum-heads—recoveries that would not in all probability have occurred under the usual methods of treatment.

While it is well known that apparently miraculous recoveries do sometimes occur under all systems of treatment, and occasionally without treatment, yet where there is an almost unbroken uniformity in the improvement of a large number of persons of all ages, sexes and occupations, afflicted with almost every form of diseases of the air passages, where recoveries are frequent and failures are rare (as has been the case in my practice during the past year) am I not justified in concluding that such results are something more than a mere coincidence?

It is not the purpose of this paper to announce a cure for consumption or any other disease, but to call the attention of conservative physicians to an apparatus and process that is indispensable in the rational treatment of the upper air passages, and the only means by which pathologic conditions of the deeper air passages can be reached or controlled.

Notwithstanding the prevalence of pulmonary diseases, there are comparatively few physicians who include the chest in the limit of their specialties. This neglect of the lungs is due no doubt to the fact that inhalations have been found inefficient, while clinical experience has proved the impracticability of administering an efficient sterilizing agent or germicide, either internally or indermically.

The use of the inhalers has been abandoned by many leading special and general practitioners, for the reason that it has been found to be impossible to introduce into the deeper passages the smaller bronchia or air cells of the lungs, either a healing or a sterilizing agent by inhalation. This fact has recently been emphasized in a series of experiments on the lower animals by Dr. H. Thomas and his assistants. These experiments prove it to be impossible to introduce by inspiration the atomized medicament contained in nebulous vapor, into the unobstructed smaller passages and healthy air cells of the animals experimented upon. The Doctor (in his paper published in this JOURNAL) states that in his clinical experience with inhalations, the most rapid improvement occurs during the first ten days treatment. This coincides with the observations of others, who have also observed that if the lungs be invaded by bacilli or are involved in degenerative or destructive processes, that the improvement is frequently followed by a more rapid decline. Hence many observers have come to the conclusion that, no matter how the

inhaler may be constructed, or how perfectly the inhalant may be prepared by its use; whether hot or cold, moist or dry, or whether a volatile or a nebulous vapor, inhalation tends to promote and hasten instead of modifying and arresting degenerative or destructive processes in lung tissue.

In my opinion there no longer exists any excuse for neglecting the treatment of those afflicted with pulmonary diseases, or for continuing disappointing and discouraging experiments with inhalers or inhalations. A physician can now procure an outfit by the use of which, in the administration of properly selected medicaments by the process of forced dilatation, he will be enabled to treat diseases of the chest with a uniformity of success equal in degree or ratio of recoveries to that following operative surgery in the treatment of other desperate maladies.

To obtain satisfactory results, the technique of forced dilatation must be carried out in detail. Physicians are not apt to do this, unless they understand and appreciate the distinctive difference between inhalation, inflation and forced dilatation, and also the difference between an impacted nebula and the smoky nebulous vapor evolved from the various nebulizing inhalers.

I am not urging a distinction where there is no difference. I am trying to make you realize the distinctive difference as I do, and as do most physicians who use the dilator for administering impacted nebula by the process of forced dilatation.

Although the efficiency of this apparatus and process can not be fully demonstrated upon dogs, cats or other dumb animals, for the reason that impacted nebula can not be forced into the deeper air passages without the intelligent coöperation of the subject operated upon, nevertheless when administered to persons who passively coöperate, its physiologic action on organs and functions and its therapeutic effect on pathologic conditions may be determined by an improvement in organic action, as manifested in the rate and character of the pulse and respirations; in an equalization of circulation and temperature; in an improvement in the processes of digestion, nutrition, assimilation, secretion, excretion and elimination, all resulting from increased aeration, through which the equilibrium in supply and waste is maintained.

Armed with the dilating apparatus, the physician is enabled to expand the collapsed smaller bronchia and air cells, and to detach, dislodge and remove by explosive expulsion such deposits as have accumulated from excessive secretion or other morbid processes. It should be borne in mind that it is behind these obstructions that the bacilli find a domicile conditioned by excessive moisture and high temperature for their vigorous activity. In the earlier stages of pulmonary tuberculosis the obstructed areas are circumscribed. In these circumscribed localities the moisture is excessive and the temperature high, as moisture can not evaporate in tubes, cells or cavities in which air through respiration does not circulate. The excessive heat and moisture in these circumscribed localities can only be absorbed or dissipated through the physiologic process of respiration and evaporation.

Let all controversy be avoided as to whether the bacilli initiate the pathologic condition by an infectious invasion of previously healthy tissue, or whether the arrest of the physiologic function of respiration

and evaporation in circumscribed localities result in a condition of high temperature and excessive moisture sufficient to develop the active and destructive bacilli from germs that previously were and otherwise would have remained inert and harmless.

Every physician has either formed his own, or else he has adopted the opinions of others on this subject. Beside investigation as to the initiative cause belongs of right to the domain of hygiene and preventative medicine.

Active and energetic remedial measures should be directed against conditions as we find them. Tempting expedients should be discarded and especially so when an agent is at hand by the use of which the physician can remove the immediate cause and otherwise control present conditions, regardless of the remote or initiative cause. When a farmer discovers that the bugs are devouring his potato vines he does not stop to inquire which or what was the primary cause. It is sufficient for him to know that if he does not kill the bugs that the bugs will kill the vines. When on examination the physician finds the lungs of his patient infested by tubercular bacilli he knows that if he does not kill them they will kill the patient. He knows that the area of lung capacity as evidenced by chest expansion is reduced, that the air passages and cells are collapsed or are obstructed in circumscribed localities. He also knows, or should know, that it is behind these obstructions and beyond the reach of inhalations that the bacilli find their favorite pabulum. That it is there they feed, fatten and propagate; that it is there the excreta and ptomaine is ejected and emitted which poisons the fountains of health, prostrates and makes sickly all the central forces of life.

Owing to obstructed blood circulation in the circumscribed localities, on account of solidification, through congestion, fibroid or tubercular degeneration, it has been found to be impossible to even attenuate the bacilli, or to arrest the degenerative or destructive processes by any agent administered either internally or indermically.

The process of preparing and administering agents in the form of an impacted nebula by the dilator offers the sole means by which recovery is possible. The collapsed, stenosed or occluded bronchia and air cells being expanded, and the obstruction removed, the air through respiration comes in contact with all surfaces. The excessive heat and moisture are absorbed by physiologic evaporation. The bacilli being first sterilized through attenuation, are finally exterminated by the germicide which is conveyed and deposited by the impacted nebula.

The benefit of forced dilatation in the improvement of the general health, is as evident and satisfactory as its mechanical and therapeutic effects are locally. More air being breathed after forced dilatation, it is thus through increased oxidation that the processes of nutrition and assimilation are improved and degenerative and destructive processes arrested. Through increased oxygenation (aeration) of the blood, constructive molecules are organized and energy is stowed, to be expended in maintaining organic and functional activity. Notwithstanding the apparent simplicity of the apparatus and process, there is sufficient scope for the employment of the most profound medical knowledge and dextrous skill in the selection, preparation and administration of the medicaments to be employed in the treatment

of the various forms and stages of diseases of the air passages.

In the selection of an antiseptic germicide to be administered in the forms of an impacted nebula, preference should be given to the following. First to the chlorides: of gold; of mercury; of iron (especially in hematorrhea); of ammonium. Second, to iodine and the iodids: bin-iodid of mercury being especially valuable; and to the sulphides or sulphates. No unfavorable physiologic effects follow their use. The menstrum for each should be alcohol and glycerin equal parts, using as little water as possible to dissolve the salts.

The volatile aromatics, in gums, crystals or essential or ethereal oils: as thymol, eucalyptol, pine needles, cubeb, tar, creosote, carbolic acid, camphor, menthol, etc., are of known value, when selected and used singly or in combination in the treatment of the air passages generally. In my practice I prefer and use those prepared by the Ozone Company of New York and Chicago, as their oils contain a large per cent. of ozone. If the secretion be excessive, alcohol and glycerin should be used as a menstrum. If the membranes are dry from scanty secretion, a neutral vegetable oil is preferable, as therapol which contains 10 volumes per cent. of ozone as prepared by the same company. All menstums used in preparing solutions to be administered into the lungs and tympanic cavities especially, should be an ingredient that will speedily evaporate or else be readily absorbed by the tissue. That elegant, odorless, tasteless and neutral carbon oil known as abolin, glymole and a score of other names, should never be used as a solvent menstrum for medicaments to be administered into any of the air passages, especially not into the tympanic cavities or the lungs. The tissue will not absorb the oil and on account of greater affinity the oil retards the absorption of the medication by the tissue.

The most serious objection to the use of the oil is the fact that the entire surfaces throughout the air passages become coated over with it. The oil will not evaporate and the tissue will not absorb it, while at the same time it prevents physiologic evaporation by excluding the air from the mucous surfaces. Thus by its peculiar behavior, it tends to arrest the processes of osmosis to a greater or less degree, which results in sub-oxidation.

Its only legitimate place in medicine is as an application to denuded, cauterized, lacerated or acutely inflamed surfaces. For the reason that its peculiar properties, as above described, makes it an agent well adapted to protect such surfaces from the air, thus preventing evaporation, oxidation and incrustation. These same properties will gradually exclude it from the prescriptions of physicians, just as the use of cosmolin or vaselin has been discontinued except in those cases to which it is adapted.

While I shall take pleasure in answering questions and giving any additional information or instruction that I can to physicians who choose to inquire, either in person or by letter, regarding the professional use of the process and apparatus, I wish it understood that I can not give any further information relating to the manufacture or sale of the same, other than to say that both my standard and hand dilators were made by the Owens Brass and Copper Works, of Chicago.

ORIGINAL INVESTIGATIONS ON THE  
NATURAL HISTORY, (SYMPTOMS  
AND PATHOLOGY) OF YELLOW  
FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Concluded from page 721.)

CHAPTER XI.

EFFECTS OF PUTRID MATTERS ON THE BLOOD.

M. Gaspard appears to have been one of the first experimenters with putrid matters. On June 19, 1809, he injected into the jugular vein of a small bitch, half an ounce of fetid liquid, arising from the simultaneous putrefaction of beef meat and dog's blood. On the instant the animal made many movements of deglutition, and very soon afterward experienced dyspnea, *malaise* and depression. She lay on her side refusing all food, and soon voided first her excrements, then her urine. In an hour's time, prostration of strength, gelatinous and bloody alvine discharges often repeated, dysentery, redness of conjunctiva; afterward, chest painful, belly hard and painful when touched; gradual extinction of strength; bilious, gelatinous and bloody vomitings. Death three hours after injection. On opening the body, yet warm, the lungs were engorged with blood and of a violet or blackish hue, with many ecchymosed or petechial spots, which likewise existed in the left ventricle of the heart, in the spleen, mesenteric glands, gall bladder, and even in the subcutaneous cellular tissue. The peritoneum contained some spoonfuls of a reddish serosity, but the mucous membrane of the alimentary canal was most affected. That of the stomach was slightly inflamed; that of the intestines, above all—the color livid, with black points, and covered with a gelatinous and bloody substance, resembling the lees of wine or the washings of flesh. In addition, this inflammation was accompanied with a slight thickening of the tissues, and possessed a hemorrhagic or scorbutic appearance.

On July 14, 1821, Gaspard injected into the right jugular of a large dog, two ounces and a half of a fetid liquid that had arisen from the fermentation for two days of cabbage leaves, at a temperature of 20 degrees R. It was thick, not at all acid and was mixed with an equal quantity of water. While injecting the animal often swallowed, and before long began vomiting, which was frequently repeated, and soon fell into a state of depression. Some hours afterward, great general uneasiness, pain in chest on pressure, respiration embarrassed, difficult and plaintive, appearance of peripneumonia, then vomiting anew and great depression all day. At the expiration of nine hours he had in the night a very fetid liquid stool, black as soot, analogous to the evacuations in *melæna*, and formed of a little excrement and mucus, with a great deal of apparently putrid blood. Some time afterward the dog had another stool, but it was merely muco-sanguineous. On July 15 (second day) depression more considerable, *adynamia*, recumbent on the side, vascillating walk, pulse small and febrile, ardent and seeming inextinguishable thirst, urine natural and abundant, respirations few and weak. During the day the pulsations of the heart would return at intervals with an extraordinary strength and noise, resembling what occurs in the highest degree of aneurysm, combined with hyper-

trophy of the organ. July 16, less depression, cessation of the disordered action of the heart, but still ardent thirst, refusal of food; fever and sometimes vomiting of drink. July 17, same condition. July 18, symptoms aggravated, extreme debility, walk tottering, excessive thirst, eyes red, inflamed and bleary, nostrils swollen and filled with mucus obstructing the passage of air, mucous membrane of the mouth violet red and phlogosed. At mid-day, liquid stool of a whitish-gray color, mixed with grumous blood, of a purulent character and odor. Death during the night at the termination of the fifth day of the experiment.

Before opening the body, the skin, subcutaneous cellular tissue and muscles presented the same appearance as after death from asphyxia from want of air, and did not appear exempt from inflammation. Conjunctiva, pituitary and buccal membranes red or violet, and covered with a thick abundant mucus, lungs of a gluey feel, slightly phlogosed in some spots, but crepitant enough. The left ventricle of the heart presented many brown spots or sort of ecchymoses, penetrating even into the tissues; it was, besides, of the color of the lees of wine which contrasted singularly with the natural color which the right ventricle preserved.

The right ventricle was in part filled up with a hard albumino-fibrous concretion, with a yellowish-white hue like fat, very homogeneous, undistinguishable from the molecules of the injected liquid, weighing two and one-half grams, almost entirely free, and only adhering to the ventricle by a small attachment. This concretion with ramifications of the same color and consistency, extended into the pulmonary artery, and into the superior vena cava, and also into the azygos, axillary, and even to the right jugular. Probably it had been the cause of the violent pulsation of the heart. The esophagus and stomach were apparently healthy, but the mucous membrane of the intestines, and particularly of the duodenum, rectum, and a small portion of the small intestines was of a violet-red, colored chiefly in longitudinal wrinkles and irregular patches, which gave a parti-color to the outside of the intestines before they were cut open. Otherwise this inflammation was without thickening of the tissues, without ulcerations and much resembled ecchymoses or hemorrhage. In the duodenum were observed many kinds of open blisters, whence a large quantity of sanious blood was made to flow by pressure on the neighboring mesenteric vein. The internal membrane of the rectum was still more affected, and its mucous glands were very swollen and distinct. The intestine contained puriform matters, resembling those of the last evacuation. The other intestines contained mucus matter of a whitish-gray color, and very thick. The mesenteric glands appeared as if penetrated by blood and altogether inflamed. The gall-bladder, stained exteriorly by brown and violet spots, was filled with a black thick bile, as ropy as melted glue.

Gaspard also performed other experiments with putrid liquids, with similar results; and he demonstrated for the first time, that putrid liquids injected into the cavity of the pleura, etc., produced the same effect as injections into the veins (*Journal de Physiologie*, tome 2).

M. Magendie, fully appreciating the important facts that since medicine has existed, the pernicious influences of ponds, marshes, neglected harbors, and in

general, all places, in which animal or vegetable matters were undergoing putrefaction, are recognized; and that men and frequently animals, inhabiting the neighborhood of these infected foci, were subject to serious maladies, which authors have designated under different names, such as the plague, intermittent fever, malignant fever, dysentery, cholera morbus, typhus, yellow fever, etc.; repeated with the greatest care the experiments of M. Gaspard, with an eye to their application to medicine, and the elucidation by the experimental method of the manner in which putrid animal or vegetable matters act upon the healthy individual. Magendie affirmed that the results of M. Gaspard were perfectly exact; and in addition he observed that different kinds of flesh have not the same activity in their putrefaction. The muscles of herbivorous mammalia appear less active than those of the carnivora. Putrefied oyster water did not cause very violent effects; but the deleterious matter *par excellence*, is putrid fish water; some drops of this water injected into the veins producing in less than an hour, symptoms which have the greatest analogy with those of typhus and yellow fever. Death usually ensued in twenty-four hours, and upon opening the body all the traces of a chemic alteration of the blood were discovered. The blood remained for the most part fluid; it had transuded through the walls of the vessels into the different tissues—particularly was it found to have traversed the intestinal mucous membrane. Blood as well as mucus accumulated in the stomach and intestines, where it presented all the intermediate hues between bright red and deep black.

Such experiments seemed to sustain the view that the healthy state of the blood in which its tendency to coagulation is very strong, prevents the transudation of the liquid through the walls of the smaller vessels. Magendie established that the same putrid matter, so deleterious when injected into the veins, has no bad effect when introduced, even in a strong dose, into the stomach or large intestines of animals; and that when putrid liquids were filtered, the animal which received the filtered liquid into its veins, experienced much less intense and much more prolonged pain than that which received the unfiltered liquid. An equal quantity of the same putrid water injected into the veins, or introduced with suitable precautions, into the divisions of the bronchia, do not produce the same effects. Injections into the lungs produce less serious consequences than injections into the veins. Magendie also subjected animals to the effluvia of putrefying vegetable and animal substances; and he thus sums up the results of these and the preceding experiments:

"From the preceding facts, it is seen that putrefied liquids when they are injected into the veins cause death, or effects which have the greatest analogy with those of yellow fever and typhus; that the prolonged respiration of putrid miasms produces death also, but in a period much longer and with symptoms which differ from the diseases I have just named. What can be the cause of such difference of the mode of action in the same substances? Why this diversity in their deleterious properties? It would be so much the more important to be able to answer these questions, as therein lies the whole difficulty, relative to the epidemic diseases which have recently occupied the public mind."

Among the conjectures which may be offered, there

is one which merits particular attention. We may presume that different atmospheric conditions, and particularly temperature and moisture, ought to have a great influence upon the mode of action of putrid miasms. (*Journal de Physiologie*, tome 3; "Speculations on the Cause of Yellow Fever," by John Harrison, M.D., Professor of Physiology and Pathology in the Medical College of Louisiana, New Orleans; *Medical and Surgical Journal*, March, 1817, vol. III, No. v, pp. 568-573.) The results obtained by MM. Leuret and Hament (*Journal des Progrès des Sciences Médicales*, 1827, vol. v, pp. 1, 181), were similar to those of Gaspard and Magendie.

The more recent experiments of Dr. Andreas Högzes, of the University of Pesth, performed during the epidemic of cholera in that city in 1873, are of interest in connection with the present discussion of the effects of putrid and morbid matters on the blood.

Dr. Högzes endeavored to solve the following questions:

1. Are fresh choleraic discharges capable of exerting a deleterious influence on the organism, and in what form?

2. Does gastric and intestinal catarrh, artificially produced, increase the liability to be affected by choleraic discharges?

3. Is the air capable of carrying with it particles or choleraic evacuations, which act injuriously on the organism; and if this be the case, is there a difference between non-disinfected and disinfected discharges, simple diarrheal dejections and putrid fluids?

4. Are choleraic evacuations, when freed from elementary organisms, capable of affecting animals?

5. What parts of disinfected and of non-disinfected choleraic discharges, does a current of air carry with it? What is the further fate of these elementary forms, if they fall on a soil favorable to their development, or on one that is neutral? In what way do they modify the action of the medium?

In his experiments, Dr. Högzes used choleraic evacuations that had been discharged an hour, or an hour and a half. The animals operated on were dogs and rabbits.

Six dogs of middle size were the subjects of experiments bearing on the first and second questions. In three, catarrh of the stomach and intestines was induced by the administration of the sulphate of copper and the subcutaneous injection of a few doses of croton oil; the other three were allowed to remain healthy. As soon as the vomiting and diarrhea had ceased in the first three dogs, Dr. Högzes administered to each of two dogs (one healthy and one diseased), fresh urine, intestinal evacuations, and vomited matters, from choleraic patients. Both dogs had intestinal catarrh (frequent vomiting and diarrhea). The dog with the sound intestinal canal was well on the third or fourth day; while one of those in which gastro-intestinal catarrh had been induced, died on the second day, having had constant vomiting and fluid evacuations; and the other two were not convalescent until the fifth or sixth day, and remained weak some time afterward.

To obtain an answer to the third question, Dr. Högzes kept rabbits exposed for some time to currents of air charged, 1, with non-disinfected; 2, with disinfected choleraic evacuations; 3, with ordinary diarrheal stools; 4, with the fluid of putrid meat. The oxygen necessary for respiration was

supplied in abundance. The rabbit in each case was confined in a glass bell jar, placed in a well ventilated apartment; the bottom of this jar was airtight, and the air, charged with the evacuations or with the putrid fluid, passed in by one aperture at the top, and escaped by another. The air having been first made to pass through the fluid of which the effect was to be tested, was forced into the jar by a Bunsen's water apparatus, at the rate of 15 liters per minute. To prevent the air from escaping in its foul state through the ventilating tube, it was made to pass through cotton wool and sulphuric acid, and in this way it was possible, without danger of injuring the health of the operator to continue the experiment for any time.

Two rabbits in one of which bronchial catarrh had been induced by the inhalation of ammonia, were subjected for twenty-four hours to a stream of air charged with non-disinfected choleraic evacuation. While under the bell the animals had slight catarrh, did not eat and were depressed. In the third twenty-four hours, violent diarrhea set in, and both animals soon became cold and collapsed; the one in which bronchial catarrh had been induced, died first, and the other five hours afterward—both presenting the same symptoms. A small rabbit exposed for twenty-four hours in the same apparatus to air charged with choleraic discharges disinfected by carbolic acid, remained healthy. Another animal of similar size was kept without injury for twenty-four hours in a current of air saturated with ordinary diarrheal evacuations. A large rabbit, exposed for twenty-four hours to a stream of air, saturated with the fluid of meat that had been decomposing during five weeks, at first lay stupefied at the bottom of the apparatus, but immediately afterward rose up, and escaped without injury.

The experiments bearing on the fourth question consisted in the injection into the jugular veins of dogs and guinea pigs, in one case of choleraic discharges containing microscopic organisms, and in the other cases of the same discharges after filtration. With regard to the last question, Dr. Högzes conducted through fresh non-disinfected choleraic discharges a slow stream of previously purified air. The elementary forms brought over with the air current were received into two media—one neutral, distilled water; and one suitable for their development, Cohn's fluid. The fluids were drawn off by drops from the vessels, and examined with the microscope. Both distilled water and Cohn's fluid have no action when injected into the vessels; and the question was, whether their action would be changed by a certain amount of saturation. In a short time, a large number of elementary forms (chiefly bacteria), with which the cholera excreta were saturated, were carried over into the fluid, and in twelve hours produced a milky cloudiness in Cohn's solution. At the end of the second twenty-four hours the surface of Cohn's fluid was covered with a bluish-green shiny layer of cryptogamic matter, 2 centimeters thick, and the fluid itself assumed a peculiar smell, reminding one of decomposing fruit. The distilled water which remained quite clear, although charged with organisms, and the Cohn's fluid were injected into the veins of dogs and rabbits. The result was, that both the distilled water and Cohn's fluid produced the same symptoms as the choleraic discharges when injected into the venous system—acute gastro-intestinal catarrh, and in some of the rabbits death.

Similar researches with discharges disinfected by carbolic acid showed that the power of development in the elementary organisms was destroyed; the Cohn's fluid still remained clear at the end of twenty-four hours. On injecting the fluids into which the air had been conveyed through the disinfected excreta, the symptoms of poisoning with carbolic acid were produced; this is readily explained, when it is remembered that the current of air in the course of twenty-four hours must have carried with it a large amount of carbolic acid.

While these experiments were being carried on, the attendant, who had been exposed for some time to the emanations from the vessels containing the choleraic excreta, had a severe attack of gastro-intestinal catarrh, which recurred twice within a short period. His little daughter, who slept with him, had vomiting and diarrhea the day after he became ill. Five days after his illness, two cases of cholera (one of which ended in death) occurred in the house in which he resided, which had hitherto been free from the disease. During the microscopic examination of the choleraic discharges, Dr. Högzes had loss of appetite, a coated tongue, and a constant sensation of oppression in the epigastrium; after the researches were completed, these uncomfortable feelings disappeared.

The following are the conclusions at which Dr. Högzes has arrived:

1. Fresh choleraic discharges exert an injurious influence on animal organisms, as it seems in different degrees in different animals.

2. The principal or infallible evidence of injury after the introduction of choleraic discharges in any way, is more or less inflammation of the stomach and intestines.

3. An artificially induced gastro-intestinal catarrh renders animals more or less liable to be thus affected.

4. The same symptoms may be produced by the inspiration of a stream of air charged with particles from non-disinfected choleraic discharges, as well as by immediate action on the stomach, intestines, or venous system; while the particles in choleraic discharges disinfected by carbolic acid, appear to be quite harmless.

5. A current of air, passing through non-disinfected choleraic excretions, carries with it cryptogamic elements, which vegetate abundantly in a favorable soil; while the same growths from discharges that have been disinfected by carbolic acid are incapable of multiplication.

6. Choleraic discharges freed from organized elements are capable, by reason of their chemie composition, of producing the same pathologic changes as they do when they contain the organized forms.<sup>51</sup>

The last conclusion established by the experiments of Dr. Andreas Högzes, is of importance in establishing the fact that the propagation of cholera does not depend on the organized elements. It may, however, at the same time be true that the fungi developed and propagated in the choleraic discharges, may become the vehicles or carriers of the poison of cholera. We have regarded the fungi found in the black vomit and other fluids of yellow fever, as in no respect the cause of the disease, but at the same time it may be regarded as probable that when developed in the poisonous matter of yellow fever they may become agents for its dissemination.

<sup>51</sup> Centralblatt für die Malarinischen Wissenschaften, Nov. 1 and 8, 1873.

I have shown by a series of experiments<sup>52</sup> on the action of the poison of the American copperhead and of the American rattlesnake on living animals:

1. The primary and chief action of the poison of the American copperhead (*Trigenocephalus centertrix*) is upon the blood.

2. The poison of the copperhead is directly destructive to the colored corpuscles of the blood, altering their physical and chemical properties and relations, and rendering them unfit for the performance of their important offices in circulation, respiration and nutrition.

3. The poison of the copperhead appears to have an affinity more especially for the coloring matter of the colored blood corpuscles.

4. Under the action of the poison of the copperhead, the animal temperature is but slightly increased notwithstanding the profound changes inaugurated in the blood; and after the establishment and propagation of the pathologic changes the temperature descends.

5. The action of the heart is increased in frequency and diminished in force under the influence of the poison of the *Trigenocephalus centertrix*.

6. The profound alterations induced in the constitution of the blood by the poison of the American copperhead, give rise to passive hemorrhages into the cellular structures, and from the intestinal mucous membrane. This phenomenon recalls strongly the passive hemorrhages in certain febrile diseases, and especially yellow fever. Such experiments indicate that the black vomit of yellow fever is the result of the action of an irritant poison upon the blood, and gastric mucous membrane. We have also in these experiments an explanation of the mode in which dysentery might be induced by a poison introduced into the blood.

7. The poison of the rattlesnake (*Crotalus durissus*) acts as a local irritant upon the capillaries, and as a destructive agent in the blood and muscular structures, causing congestions and bloody effusions, and softening and disorganizing action of the muscular fibers.

8. The poison of the rattlesnake destroys by its direct effects upon the cerebro-spinal centers, and by its depressing effects upon the sympathetic ganglia, and muscular structures of the heart; and also by the changes which it induces in the composition of the blood.

If therefore a few drops of a secretion elaborated by special organs in living animals in a normal state be capable of producing profound disturbances in the blood and nerves and muscular systems; it can not be unphilosophical to refer the origin of certain diseases, as typhus fever and yellow fever, to the action of special poisons arising in the human body when subjected to certain conditions of food, climate, moisture and the foul air arising from overcrowding.

Another striking fact is that a deadly volatile poison may be generated during the fermentation or chemical and physical changes of certain vegetable constituents. Thus by a series of experiments<sup>53</sup> we have shown that the volatile poison hydrocyanic acid (prussic acid) induces profound alterations in the blood, and through this medium affects all the

organs and tissues. We have endeavored to open the vast field of the action of well-known poisons, in order to elucidate the nature of the unknown febrile poisons.<sup>54</sup>

It is surely worthy of note that the most destructive vegetable product is the direct result of fermentation and is volatile.

Such facts may be plausibly adduced to show that a deleterious agent capable of producing yellow fever might be the product of animal and vegetable matters under different ranges of temperature. The conjecture has been hazarded that the poison of this disease resembles a volatile essential oil and which in conjunction with the albumin and ammonia of the atmosphere induces the phenomenon of yellow fever. They may also be adduced to sustain the hypothesis that the poison may be engendered in the human system under certain circumstances, and may be propagated through the medium of the atmosphere and by the agency of fungi and animalculæ.

THE END.

## PRE-COLUMBIAN LEPROSY.

BY ALBERT S. ASHMEAD, M.D.

LATE FOREIGN MEDICAL DIRECTOR, TOKIO HOSPITAL, JAPAN.  
NEW YORK.

(Continued from page 723.)

Mr. Saville tells me that in the pottery of ancient Mexico there are symbolic pictures of death; human faces with blinded eyes. It is at least his opinion that this extinction of the eyes means death; for the god of death of these peoples is always represented with a stick puncturing the eyes. But nothing that can be considered as disease representations has ever been found there.

In Chiapas, Mexico, he says images have been recently found showing clubbed feet, arms in cramped positions, etc. This find is believed by archaeologists to be exceedingly valuable, but it has not been, as yet, much reported upon.

If leprosy existed in America in pre-Columbian times, and if these deformations on *huacos* pottery are intended to represent lepers, the same idea must have been conceived previously in Japan, or Eastern Asia in general, from whence the disease itself would be likely to have come. But Prof. Edward S. Morse writes me: "The pre-historic pottery of Japan has no trace of lepers either incised, in relief, or painted. Nor do the forms ever represent a natural object. In early historic times, say from 1200 to 1500 years ago, a soft reddish pottery hand-made, and a hard gray pottery, turned but not glazed, in very rare cases, showed the form of natural objects."

Mr. Tanaka, a Japanese importer, who is probably as conversant with modern Japanese pottery and art as any man living, affirms that he never saw the representation of a leper, either in pottery or in the drawings of Japan.\* The blind man is represented; he is, in fact, considered as possessed of virtues and

<sup>52</sup> Et seq. Medical and Surgical Memoirs, vol. I, pp. 272-532.

\*NOTE.—In the "Japanese Manual for Ladies," a book on etiquette published in the eighteenth century, there is a drawing of the Empress Gemmyo (A. D. 708-721) who washed a thousand lepers with her own hands and took general care of them. (She built the first leper hospital in Japan.) In this picture a tuberculated leper is represented. He has the leonine face, without, however, loss of nose. In a Japanese book called "Hakkenden," which means "Story of Eight Warriors," written early in this century, there is a representation of a leprosy beggar. He is without a nose and without hair; his red face is hypertrophied and tuberculated. His upper lip is represented much swollen and tuberculated. His toes are gone, the hands show scabs and tubercles. These are the only representations of leprosy known in Japan. I may say that the loss of nose and upper lip in Japan is frequently observed in the streets. This deformation in Japan, which is a leprosy country (there are 100,000 lepers in Japan) is considered always as syphilitic.

<sup>53</sup> British Medical Journal, Dec. 13, 1873, p. 697-698. Medical and Surgical Memoirs, Vol. I, pp. 519-529.

<sup>54</sup> Medical and Surgical Memoirs, vol. I, pp. 279-330.

powers refused to the crowd of men with regular eyes; he is the massager and acupuncturer.

Under the reign of the Empress Suinin (A. D. 29-70) the custom prevailed of burying living retainers around the body of their masters. The living beings were replaced by small images of clay, and that new custom continued until 700 A. D. In 700, cremation began; it was first practiced by a Buddhist priest. When the custom of cremation extended, the burial of retainers, or of clay images, had no longer any significance in the mind of these primitive peoples. These accompaniments were intended for a body, not for a heap of ashes. Cremation was, in Japan at least a Buddhistic, a religious institution. It was not intended and especially used for the destruction of leprous cadavers. Even now lepers are excluded from the burial rites of cremation. It is probable that even in our day there is more cremation than interment in Japan; but lepers are severely excluded from the former. We might very plausibly conclude, I think, that if leprosy came to this country from East Asia, the absence of skeletons with leprous indications is very significant; for, as I have just said, leprous bodies were not cremated, and therefore ought to be found occasionally. Even if these bodies had been as a rule cremated, would not some of them, or parts of them have escaped the incineration? If we can not find any trace of the mutilations peculiar to leprosy, we may safely conclude that leprosy did not exist at all here.

Dr. Brinton and Professor Powell assert that the civilization of America is autochthonous; that is, it did not come from East Asia, or from any other country. Let us now ask ourselves here what autochthony after all means? Can it mean, according to etymology, anything else but the origination out of certain ground, certain environments, and certain circumstances of certain conditions of life? There must be evidently diseases which originate in circumstances which are only found in the place where they originate; and these I should call autochthonous. What is, after all, the meaning of autochthony, speaking of diseases? It is natural to suppose that in every human body there are all the possibilities necessary to produce any disease. Call them germs, or what you will. Suppose that an individual in the city of New York finds himself and his possibilities placed by chance in such a condition that a disease, up to his time unknown, develops in him and that, in some manner, it is transmitted. Well, the disease would be autochthonous in New York, as yellow fever probably was in Yucatan. Now it is extremely reasonable to believe that at the same time, or at some other time, before or after, the same phenomena had occurred in many other places. If we consider this, to what does the autochthony of disease come?

Is leprosy autochthonous wherever we find it, or must we suppose that it comes in every case from inoculation?

If leprosy existed in America before Columbus, if not autochthonous, it must have come from East Asia, or indirectly from its ancient home in Africa, or else these countries were inoculated from America. I believe that the lepræ bacillus requires its own soil to thrive upon and that most individuals would resist its development as well as other disease germs are resisted. I, for my part, do not believe that the lepræ bacillus is the real factor in the production of leprosy, or that a bacillus is the

real cause of disease. I believe that there is a cause of the disease of which the bacillus is only a symptom. What the nature of that cause is I can not say, and nobody can say; modes of life, kind of food, peculiarities of climate, clothing, morals, etc. In all cases, where certain conditions belonging to these factors exist, it may be that the same kind of bacilli find their living; the microbes may have nothing to do with it, except that under these conditions alone they can live. Under certain conditions of life, certain bacilli take birth. It is not the bacillus that is the cause of the damage that ensues; it is the condition which allows it to prosper.

Professor Stillé says: "The supreme puzzle is the primary source of each specific germ. As yet no Darwin has arisen to show even the possibility of the evolution of such germs. To name them bacteria, and assign to each disease a specific bacterium, only removes the difficulty one stage backward."

If the ancient races of America came from East Asia it is reasonable to suppose that they came through Japan, Yesso, the Kurile Islands and Aleutian Islands. There are stone age, arrow head connections between Japan, Yesso, the Kurile and Aleutian Islands; there are syphilitic connections between Japan, Vancouver, Mississippi mound-builders and Mexico. There is no connection in pottery, or in modes of burial between these two civilizations. There is, however, a skull connection between the Indians of Mexico (Tarahumares), ancient Arizonians (Saladoans) and ancient Peruvians. From these facts we may suppose that there was a migration from East Asia to America.

There is no evidence from Behring's Strait down to South America, that any leprous inoculation took place through this migration. If any leprous inoculation into Peruvian populations took place, it must have been either through the Spaniards or, as Le Plongeon assumes, directly from India. It could not have come through the islands of Japan, that is preceding their occupation by the present Japanese race; for the Ainos, as long as history knows anything about them, never were afflicted with leprosy, and they are immune to-day.

We must therefore conclude that if leprosy came from India to America, it must have come by another route than that which brought syphilis.

(To be continued.)

**A Second (1) Case of Ocular Diphtheria Treated by Sero-therapy**  
By Dr. H. Coppez. (*Journ. de méd. et de chir. de Bruxelles*, November 24.) A detailed description is given of this case to emphasize the special character of the stage of repair following the injection of serum. The false membranes, says the author, disappear more or less rapidly and leave behind them healthy tissue. There is no period of suppuration or repair. The disease is cured at the outset. The disappearance of the false membranes takes place in inverse order to their appearance. "They seem to melt like a snowflake in a ray of sunlight," is the picturesque expression of Professor Coppez, or in more scientific terms, they seem to disappear by a process similar to that by which they came. It is superfluous to dwell longer on the important rôle played by sero-therapy in the treatment of ocular diphtheria. Thanks to the injections of antitoxin, we are in a fair way to check the invading progress of pseudo-membranous exudates. Better still, the last two stages of the malady may be suppressed, with all the dangers that accompany them. In short, with this new treatment, when the false membrane has once disappeared the disease itself is conquered. If treatment is begun at the proper time it will not be forty-eight hours before all the menacing symptoms have disappeared, and the physician will be gratified by the rapid and complete recovery.—DASTOR, in *Annales D'Oculistique*, January, 1895.

## ASSOCIATION NEWS.

## AMERICAN MEDICAL ASSOCIATION.

OFFICIAL REPORT OF THE PROCEEDINGS IN GENERAL SESSION,  
1895, OF THE FORTY-SIXTH ANNUAL MEETING, HELD IN  
BALTIMORE, MD., MAY 7, 8, 9, AND 10, 1895.

## MAY 7—FIRST GENERAL SESSION.

The Association convened in the main auditorium of the new Music Hall, and was called to order at 10:30 A.M., by the President, Dr. Donald Maclean, of Detroit, Mich.

Prayer was offered by the Right Rev. William Paret, M.D., Bishop of Maryland.

The President invited all ex-Presidents and Vice-Presidents to seats on the platform, and among those who complied with the invitation were Drs. N. S. Davis of Chicago; Henry O. Marcy, of Boston; W. B. Rogers, of Memphis; Jas. F. Hibberd, of Indiana.

President Maclean then introduced the Hon. F. C. Latrobe, Mayor of Baltimore, who delivered the following

## ADDRESS OF WELCOME.

*Ladies and Gentlemen:*—It is an agreeable duty, in fact, a great pleasure, for me to have the honor of extending to the members of the American Medical Association a sincere welcome to Baltimore. Although by profession a lawyer, no one has a greater or more profound respect for the sister profession of medicine than myself. Both of our callings are occasionally slandered; in fact, some have been bold and had enough to call us necessary evils. I once knew an old lady who had never been sick, who said: "If I should be taken ill send first for my lawyer, then for my doctor, and when they get through with me, go right off for my preacher."

But we members of these learned professions have the proud satisfaction of knowing that among the men who have won honor in the land and who have added to the fame of our people none are more numerous than those who came from the ranks of medicine and law.

We have looked forward, ladies and gentlemen, for some time to the pleasure of your visit. We shall be glad to show you our hospitals, our asylums, our universities, our libraries and colleges, our monuments and our parks, and last, but not least, our city, whose people are ready and anxious to extend to our visitors a kindly and cordial greeting. We especially thank you, gentlemen, for bringing such a large number of ladies with you. Some one has said and, I think, with truth, that a man is always safer in traveling when accompanied by his wife.

If I was a doctor and a patient contemplating visiting another country or great city consulted me on the subject, I am sure I could give him no better prescription. Ladies, I extend to you a double welcome. Should any of our visitors desire to see the seat of the municipal government I offer you a sincere invitation to visit the City Hall. If the ladies will come, I hope they will bring the gentlemen with them.

In the name of this city and its people, I bid you all welcome to Baltimore.

MAYOR LATROBE was followed by Dr. Samuel C. Chew, who, on behalf of the Committee of Arrangements, welcomed the Association for the local profession.

DR. CHEW was warmly received on rising to speak. He spoke in part as follows:

*Gentlemen of the American Medical Association:*—The medical profession of Baltimore tenders to you a most cordial and fraternal greeting. Eight and twenty years have passed since this city was last honored by your presence here, and the changes which in that time have taken place in the Association, and in the world around us, are a measure of the changes—happily advances in knowledge—which have occurred in medical science. Since then a whole generation of physicians has largely passed away. Another generation has come into existence, so that of those active and strenuous workers in the profession who are here to-day many had then not entered it, and some no doubt were unborn.

The old order has changed and yielded place to the new; and, if such difference exists in our Association, how different, too, were our surroundings at that time. In 1866 the population of the United States was 35,000,000; now it is nearly if

not quite, 70,000,000. Baltimore when you were last gathered here, was a city of about 250,000 souls, and now she numbers 500,000. But a more important change in its interest to our profession than mere increase of population is found in the fact that this city has become one of the chief centers of medical education in the country, and as such attracts here about one thousand medical students every year.

Again, at your former meeting here the swell of the storm of civil conflict had not yet wholly subsided; some of its sad results were in many places still manifest and flagrant, and among them was the retardation of medical progress. For, if in the midst of arms the laws are silent, so too, the voice of science is hushed or lowered. Peace is the atmosphere in which she flourishes and achieves her greatest triumphs.

DR. WILLIAM OSLER then reported on behalf of the Committee of Arrangements, and offered the program as the entire work of the meeting. He also announced the following receptions and entertainments:

## TUESDAY, MAY 7.

1. Section Dinners.
2. Reception at Dr. Robert W. Johnson's.
3. Reception at Dr. Howard A. Kelly's.
4. Reception by Dr. Julian J. Chisolm.

## WEDNESDAY, MAY 8.

Hospitals open for inspection: University of Maryland, Baltimore Medical College, College of Physicians and Surgeons, Baltimore University. Reception at Johns Hopkins Hospital, 8 to 10 P.M.

## THURSDAY, MAY 9.

Fête Champêtre at Sheppard Asylum, 5 to 7 P.M. Reception at New Music Hall, 9 to 12 P.M.

The following Clubs offered their privileges to the members of the Association during their stay in Baltimore: Athenaeum Club, University Club, and Catholic Club. To the ladies, "The Arundel Club."

PRESIDENT MACLEAN then delivered his ADDRESS, which was punctuated throughout its delivery with applause.

DR. J. MILTON DUFF, Pittsburg—I move that the thanks of the Association be tendered to the President for his able address, and that it be referred to the Committee on Publication.

Seconded and carried.

DR. A. L. GIBON, Washington, D. C.—I move that that part of the President's Address which pertains to a Bureau of Public Health be referred to the authorities at Washington who are engaged in establishing such a bureau. Seconded.

DR. QUIMBY, New Jersey—In order to make the matter a little more effective, I move, as an amendment, that the portion of the President's Address alluded to be referred to a committee of three, with Dr. Gibon as Chairman, to present it to the authorities at Washington. Seconded.

DR. GIBON—I differ with Dr. Quimby. I do not think the authority of three men would be greater, and I am satisfied to let it go as coming from the President of this Association alone, and in his own words.

DR. QUIMBY withdrew his amendment.

THE PRESIDENT then put the original motion, which was carried.

The Permanent Secretary read a communication from the Judicial Council as follows: Decision of the Judicial Council of the American Medical Association in the case of the Medical Society of the State of Pennsylvania, versus the Trustees of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

"Having examined the testimony brought before it, the Judicial Council of the American Medical Association find some objectionable advertisements have inadvertently appeared in the JOURNAL of the Association and have given the Board of Trustees and Editor of the JOURNAL official notification of the fact.

Signed, H. BROWN, President, *pro tem*.

Attest, JOHN B. ROBERTS, Secretary."

DR. FERROUSON asked if the communication was open for discussion, to which the President replied in the negative, and decided that this action was final.

DR. SOLIS-COHEN, of Philadelphia, offered the following:

*Resolved*, That the report of the Board of Trustees be made the special order for to-morrow, Wednesday, immediately after the report of the Committee of Arrangements, and that it then be referred without discussion to a special committee of three, who shall report on Thursday morning in the place now assigned to the report of the Trustees. Seconded.

DR. E. F. INGALS, of Chicago—I have no objection to that resolution, except this, that the report will not be ready to be made to-morrow.

DR. SOLIS-COHEN—I have introduced that resolution at the request of a number of members of the Association, not only in Pennsylvania but in various sections of the Union. They consider that the conduct of the JOURNAL of the Association is one of the most important subjects which can come before this meeting. They wish it discussed calmly, deliberately, at a certain time, and with accurate data before them.

DR. JOHN B. HAMILTON, of Chicago—Mr. President, I rise to a point of order.

THE PRESIDENT—Please state your point of order.

DR. HAMILTON—The gentleman is not speaking to the question, but is discussing the action of the Board.

DR. SOLIS-COHEN—I am speaking to the resolution. The object of this committee is to digest the report, to consider the criticisms that have been offered publicly, and to further consider what the Trustees have to say in relation thereto calmly, deliberately, without prejudice, and then report to the Association at a time when it can again be calmly discussed by the Association with all the necessary data before it. It is to prevent hasty judgment, favorable or unfavorable, that this resolution is offered. It is offered as a means of peace, as a means of carrying out the will of the Association, as a means of elevating the JOURNAL of the Association to the proud position that it ought to occupy as the leader and not the follower of the medical press of the United States. (Applause.) Therefore we ask that this resolution be adopted.

DR. GRAHAM, of Chicago, also stated, as a member of the Board of Trustees, that the Board would not be able to report at the time mentioned.

DR. J. COCHRAN, of Alabama—I move that the resolution which has been presented be laid upon the table. Seconded.

DR. HAMILTON—I rise to a point of order. The Board of Trustees being a standing Board, authorized by the Constitution of the Association, its report can not be referred to a special committee, except by unanimous consent.

THE PRESIDENT—The point is well taken.

DR. FERGUSON, of Troy, N. Y.—I rise to a question of information. I understand that the resolution offered by Dr. Cohen does not call for a reading of the report of the Board of Trustees, but that it is to be presented to a committee, and then the whole matter goes over, so that the action of the committee can be simultaneous with the actual reading of the report. It is well for the Association to understand this. If there is to be a committee appointed, and that committee is to act upon the report, it is as well that it should be appointed, so that during the preparation of the report they may be taken into the meeting of the Board of Trustees, and then we shall not have to wait until the eleventh or twelfth hour for their action.

THE PRESIDENT then put the motion to table Dr. Cohen's resolution, which was carried.

DR. E. F. INGALS—In order that every member may be satisfied, I would move that a committee be appointed at this time to consult with the Board of Trustees and to make such suggestions as they deem necessary, if there are no objections.

DR. COHEN—That is perfectly satisfactory to us, and I therefore second the motion.

DR. COCHRAN—I desire to say a few words with regard to the resolution. To my mind this is a very important question. It is a proposition to appoint a committee to sit in judgment upon our Board of Trustees. It would seem as if you can not trust the Board; that the Board of Trustees are a lot of bad boys; that they are not fit for the positions they occupy; that therefore you want to appoint a committee to make them behave themselves. I feel that this is dishonoring to the Board of Trustees. (Applause.) If I were a member of the Board and such a resolution was passed, I would immediately resign. It is all child's play to be appointing masters over them. Who is this Board of Trustees? I am going to read the names of men you all know. They are men you respect; they are men who have the confidence of this Association and of the medical profession, as well as of the people of this country. They are not school boys; they are not fellows with shady characters, but men of great reputation. One of them is Alonzo Garcelon. Another is Perry H. Millard. (Applause.) Another is J. W. Graham. (Applause.) Others are E. E. Montgomery, E. Fletcher Ingals, John E. Woodbridge, J. T. Priestley, Joseph Eastman, and David W. Graham. (Loud applause.) Now, you ask to have a committee appointed to supervise the work of these men. I say it is dishonoring to them, and they ought not to submit to it, and as an Association we ought not to put this indignity upon them. I believe in being virtuous; I believe in the ten

commandments, in the Golden Rule, and all that, but there is such a thing as being too virtuous. (Laughter.) I want to say right here, that advertisements of the character that appear in the JOURNAL of the Association appear in every medical periodical that is published in the United States of America—every single one, I believe, certainly the majority of them. These periodicals are all conducted by honorable men, and they are at least a fair sample of the profession, and yet you want to make rules and impose regulations upon the JOURNAL that you do not require anybody else to submit to. (Applause.) There is another point with regard to the Board of Trustees that you might bear in mind, and it is this, that the American Medical Association is not a chartered body. It can not sue and be sued. The Board of Trustees are responsible for the expenses incurred in the publication of the JOURNAL. I have mentioned the names of the gentlemen composing the Board, and I hope this motion will be laid at rest by one vote. I therefore move, Mr. President, that it be laid upon the table. Seconded.

The reading of the resolution was called for, and it was read by the Secretary.

THE PRESIDENT put the motion to table and declared it carried, when Dr. Cohen rose and called for a division. There were 138 votes in favor of tabling the motion and 108 against it. The President then declared the motion carried.

The following was offered by Dr. P. H. Millard:

WHEREAS, Membership in the medical corps of the Navy of the United States from having been, through its high professional attainments, once eagerly sought by graduates of medical colleges, has ceased to be attractive to them, so that it is no longer possible to fill its vacancies; and

WHEREAS, It is believed that this is due to the inferior rank given to entrants to the corps and their assignment, when at sea, to quarters in the steerage, with undergraduates of the Naval Academy and civilian paymaster's clerks, while the young medical officer of the Army begins his career a grade higher and in the commissioned officers' mess; and

WHEREAS, The professional requirements and qualifications, the professional duties and obligations of the medical officers of the Army and Navy are identical; therefore be it

Resolved, That the attention of the Senate and House of Representatives of the United States be invited by the American Medical Association to this inequality, and that the Naval Committees of the two Houses be urged to inaugurate such legislation as shall confer upon the officers of the medical corps of the Navy the same status, pay and emoluments as are now accorded to the medical officers of the Army.

Resolved, That this resolution be printed and copies of it certified by the President and Secretary of the Association, shall be sent to the President of the United States, the Secretary of the Navy and to every member of the LIVth Congress.

DR. X. C. SCOTT, of Ohio—I move that the resolution be adopted as the sense of the Association. Seconded and carried.

The following was presented by the Business Committee:

"The Business Committee requests the Association to direct the officers of the Sections, at their afternoon sessions of Tuesday, to appoint members to serve as substitutes on the Business Committee in place of those who are absent during this meeting of the Association.

"The Business Committee also requests the Association to make this order such as will operate at all future meetings of the Association, or, if necessary, to amend the By-Law relating to the Business Committee to this effect."

DR. JOHN M. DUFF, of Pittsburgh—I move that the request of the committee be granted. Seconded and carried.

A telegram was received from Dr. Rand, of Oregon, asking that the Section on Dermatology and so much of the work as pertains to genito-urinary diseases be consolidated.

DR. HENRY O. MARCY, of Boston—I move that this consolidation be made. Seconded and carried.

DR. LEARTUS CONNOR, of Detroit—In order to act intelligently on a definite, distinct and difficult matter, it is necessary to acquire certain information. The information we desire to obtain is this: What proportion of the members of the American Medical Association prescribe proprietary medicines, and what proportion do not? If we can settle this by collective investigations, then we shall know where we stand, and we can definitely understand what the Trustees ought to do in the matter of advertising. If the majority of the medical profession of this Association do not prescribe proprietary medicines at any time, then the Trustees ought not to admit any advertisements respecting them into the JOURNAL; but if they do prescribe them, then the majority ought to rule and the question be stopped. Therefore, I move that a committee of three be appointed who shall take means to ascertain during the coming year the proportion of members of the Association who prescribe proprietary medicines.

DR. A. L. GIBON—If such a committee is appointed, I hope Dr. Connor will be appointed its chairman. The resolution amounts to this, that one-third of us are either ethically

pure, or that two-thirds of us are practically empirics, whatever we may be theoretically.

DR. EDWARD JACKSON, of Philadelphia—If I rightly understand the matter, it is Dr. Connor's intention to settle the question which has been raised in the Association, and I would move, as an amendment, that we say "secret proprietary remedies." The question at issue is not with reference to proprietary remedies in general. Seconded.

DR. E. D. FERGUSON, of Troy—I do not think it is possible to poll the members of this Association to ascertain just exactly what their conduct is in that respect. There is a broad distinction here which has not been made by Dr. Connor. The fact that a new remedy has been discovered, and that some one outside of the profession has made it proprietary, is not by any means a logical or right interpretation of our Code of Ethics. The questions of proprietary and secret preparations are two very important ones, and we should keep clearly in mind as to whether we prescribe phenacetin, a simple, definite chemic compound, or antikamnia, which I have never done, nor have I prescribed a secret remedy of any kind. Inasmuch, therefore, as this resolution does not in my judgment carry with it a desire to get at the truth, but that it tends to create confusion; that it wishes to bring into the arena the discussion of points that do not properly belong here, I move that the whole thing be laid upon the table. Seconded and carried.

After the various State delegations had been instructed to meet immediately after the adjournment to select members of the Nominating Committee, the Association, on motion, adjourned until Wednesday, 10 A.M.

#### MAY 8—SECOND GENERAL SESSION.

THE PRESIDENT called the Association to order at 10:30 A.M. The minutes of the preceding session were read and approved.

The Permanent Secretary read the following:

Upon the request of the Section of Materia Medica and Pharmacy, the General Business Committee has directed me to inform you that there are in attendance at the meeting of the Association, delegates from the American Pharmaceutical Association, with the request that you extend such courtesies to said delegation as you may deem proper.

Signed, L. D. BULKLEY, Secretary.

DR. HENRY D. HOLTON, of Vermont—I move that the delegates of the American Pharmaceutical Association be invited to take seats on the floor and given the courtesies of the Association. Carried.

DR. OSLER, for the Committee of Arrangements, announced several invitations.

The Permanent Secretary read the list of the Committee on Nominations, as reported from the several State delegations:

#### COMMITTEE ON NOMINATIONS.

Alabama, J. C. Lefrange.	Missouri, I. N. Love.
Arkansas, L. P. Gibson.	Montana, G. W. King.
California, H. B. Ellis.	Nebraska, M. L. Hildreth.
Colorado, J. W. Graham.	New Jersey, I. N. Quimby.
Connecticut, W. S. Watson.	New York, E. D. Ferguson.
Delaware, R. G. Ellegood.	North Carolina, C. J. O'Hagan.
District of Columbia, C. H. A. Kleinschmidt.	Ohio, A. B. Walker.
Georgia, F. Westmoreland.	Oregon, H. R. Holmes.
Illinois, John B. Hamilton.	Pennsylvania, W. M. Welch.
Indiana, J. L. Thompson.	Rhode Island, W. R. White.
Iowa, J. T. Priestley.	South Carolina, T. J. McKie.
Kansas, M. B. Ward.	Tennessee, J. C. Reeve.
Kentucky, T. B. Satterwhite.	Texas, S. E. Hudson.
Maine, T. W. Foster.	Vermont, D. C. Hawley.
Massachusetts, A. H. Tuttle.	Wisconsin, W. H. Washburn.
Maryland, G. H. Rohé.	U. S. Navy, T. C. Walton.
Michigan, D. Laferte.	U. S. Marine-Hospital Service, G. W. Stoner.
Minnesota, P. H. Millard.	

DR. GIBON, Chairman of the Rush Monument Committee, read his report, as follows:

#### REPORT OF CHAIRMAN OF RUSH MONUMENT COMMITTEE.

The committee to which has been intrusted the collection of a fund for the erection of a monument to the memory of Doctor Benjamin Rush, in the City of Washington, on the part of the members of the medical profession of this country, as an evidence of their appreciation of the eminent services of this distinguished patriot-physician of the Revolution, begs to report that this fund now amounts to \$3,091.39, of which \$3,000 are invested in bonds and mortgages bearing 5 per cent. annual interest. Your committee regretfully admits that this is but a sorry showing beside the success of the American Surgical Association in collecting all the funds they required for the erection of their projected statue to Dr. Samuel D. Gross, of Philadelphia, and can not but experience a sense of mortification that an association of such limited membership as the latter should have accomplished so much in so short a time, while the entire body of physicians in America, as represented by the American Medical Association, has done so little for this

enterprise, upon which they entered with enthusiasm eleven years ago.

It is almost an ungracious reflection upon the intelligence of the members of this Association to repeat in detail the reasons why a statue should be erected to Benjamin Rush. The most eminent of the living members of our profession have eulogized him as "the greatest physician this country has ever produced," as "the founder of scientific medicine in America"—as "one of the most notable men of his time, whose views were half a century ahead of the times." The great medical authorities of Europe have given him unstinted praise as the American Fothergill, the American Sydenham, the American Hippocrates—best of all, as the American Rush. It "being unjust," says this eulogist, "to compare him with any other." Go to the Department of State at Washington and ask to see the Declaration of Independence, which converted thirteen British colonies into thirteen sovereign American States, and you will read the name of Benjamin Rush written upon it one hundred and nineteen years ago, that of the only practitioner of medicine who signed that immortal document, and for that act alone we, practitioners of medicine, ought to commemorate him by this monument. Or, read the proceedings of that convention which framed the Constitution that bound these thirteen sovereign American States into this United States of America, and again you will see the handwriting of Benjamin Rush, of Pennsylvania. The history of the United States records this man as one of the most active, fearless and pronounced of its rebel founders. In committees, in conventions, in the Continental Congress, to which he was elected when timid men fell out, Dr. Rush was conspicuously present and his eloquent voice was heard in a cause which meant the freedom of his country or his own death by the halter. In the early history of our profession in America the name of Rush is so interwoven with the warp of events that it is an ever prominent figure in the fabric. He was a civilian practitioner, hospital physician and military surgeon; he was the standard authority among alienists, at home and abroad, down to our very day; he was an advanced sanitarian before hygiene was admitted to be a legitimate branch of medicine; he was a thoughtful epidemiologist in his youth, when other youths had not yet quit their rudiments. Eloquent as a lecturer, unrivaled as a teacher, prolific as a writer, a professor at 24 in that great school which he did so much to make great, he died, practicing his profession, at 68 from typhus pneumonia, while fearlessly encountering, studying and combating the frightful pestilence of 1813. Many of you have liberally contributed to monuments to generals, slain upon the battle-field, but was there ever a soldier who faced a deadlier foe than this, with greater courage than his, or died more bravely, honorably and gloriously than he died, trying to save other men's lives, instead of seeking their slaughter.

Where in the long line of our professional worthies can you find one more worthy of being portrayed to posterity as the representative physician of America? He studied medicine as thoroughly as it could be studied at that day, giving seven years to it after receiving his degree of Bachelor of Arts; he taught medicine to more than two thousand private pupils; he was a part of the social life of the community in which he was established, and by which he was regarded as a wise counselor, intrepid and undaunted in public assemblies during the critical birth-throes of the Republic, and as brave a soldier as ever honored the uniform he wore. Whether in his boyhood, his adult manhood, or his always virile old age, through his whole career and in the circumstances of his death, the profession of medicine will find only something honorable and something to honor. He, and he alone, impersonates the principles this monument is intended to weld in imperishable bronze. Fortunately, sadly, in his splendid portrait, painted soon after Rush's death, the original of which is one of the most treasured possessions of the Pennsylvania Hospital, has preserved for us the benevolent features and dignified form of this great, good doctor.

Your committee does not seek to detract in any measure from the high estimate of that grand surgeon—"the father of American surgery" he has been aptly termed—whose projected statue is an accomplished fact, and the Chairman of this Committee has, least of all, the thought of minimizing in any degree one whose personal relations with him were of a peculiarly affectionate character, but, according him all praise, and rejoicing that he is to be so commemorated, your committee reminds you that he was of our own day, while Benjamin Rush was one of the fathers of the Republic, whom Gross himself regarded with reverential and respectful homage.

Were your committee less earnest and enthusiastic in the belief that the monument to be erected to this greatest of American doctors should be one befitting a body of professional men, now numbering about one hundred and ten thousand, it would advise that the \$3,000 in its hands be expended for a simple bust to stand upon a plain granite pedestal, but it is unwilling by doing so to make ineffaceable record of the fact that this great army of one hundred thousand members of the noblest of the learned professions was unable or unwilling to contribute more than an average of less than three cents apiece to honor a man of whose like but one in a century appears in the history of a nation, and especially does it shrink from this conclusion of its work since the successful completion of the undertaking of the young association, which numbers but one in every thousand of the medical fraternity of the country, and which was only organized four years before this body unanimously and enthusiastically

"Resolved, that this Association undertake to erect a statue to Dr. Benjamin Rush, in the City of Washington, by the members of the profession of medicine in the United States."

It is to the infinite credit of the members of the American Surgical Association and their supporters that they have thus honored one who deserved all honor from his colleagues, pupils, friends and admirers; it will be to our infinite discredit if we do less. As Chairman of the Rush Monument Committee, I can and do most heartily congratulate my old and highly esteemed friend, Professor Mastin, of Mobile, the Chairman of the Gross Monument Committee, and I hope to be able to accept the cordial invitation he has already tendered me to witness the unveiling of a work, which has been with him and his associates, a veritable labor of love. There need be no envy of their success, on our part, but only increased incentive for us to do what has become with every year that has passed, a more solemn duty for us, and an increasing labor of love.

It is quite a different matter than fraternal emulation, when it is announced that a monument to Hahnemann is soon to be erected at the National Capital, and if the beautiful artistic design for that monument which I have seen, shall be adopted and executed, more than ever will it be incumbent upon the physicians of America to place no inferior memorial of their own great archrival beside that of a foreign theorist, whose vagarious travesties of medical truth have at most served to enrich a few pseudo-physicians, who have been willing either ignorantly, unconsciously, or deliberately to mountebank medicine for the gain it has brought them. With such a rival in the field, it behooves us to be up and doing, and we come now to ask your very serious, thoughtful consideration of the ways and means of doing. The spasmodic contribution of a few dollars by a few individuals, under the influence of

personal appeals, at these annual meetings is not enough. A few days ago I completed forty years' service as a commissioned officer in the Navy, and in a few months the legal limitations of age will retire me from active service, and I can never again appear before you as the official representative of a corps with which I have been identified for nearly half a century; nevertheless, I am willing to make the erection of this statue the earnest effort of my future, as it has been my past, but I beg of you now, if you believe this work can be more speedily and satisfactorily accomplished in other hands, to relieve me of the charge, since if I am to continue this work, it must be done with no longer delay, for at three score and two, no man can count upon years, or months, or days, ere his name shall be called on the muster-roll of the dead. Already since the inauguration of this project, Austin Flint, your honored President, who appointed the original committee of seven, and three of these seven, Henry H. Smith, of Philadelphia, Robert A. Kinlock, of Charleston, and John C. Murphy, of St. Paul, have gone beyond the possibility of witnessing its completion, as have Lewis P. Bush, of Wilmington, Del., Surgeon M. K. Taylor, U. S. Army, of Fort Sill, Ind. Ter., and I fear one or two others of their successors from whom I have not heard.

I, therefore, submit to you to decide at this time, and there is no more important subject for your consideration at this meeting, what you, members of the American Medical Association, and you, delegates, who are here representing National, State, county and municipal organizations all over this country, are willing to do as active coadjutors in this effort to erect a monument to Dr. Benjamin Rush, as illustrative of all that is great and good in medicine, and typifying at the Capital of the Nation the part that our noble profession has had in the foundation of this great Republic.

Your committee should be reorganized and enlarged by a representative from every National, State, Territorial and district organization, these to act severally as chairmen of sub-committees, composed of members from each county, municipal and local society in their respective departments, States, Territories and districts. An efficient working general committee must be composed only of members willing to discharge their onerous duties. The experiment of issuing a coin-card to individual physicians, with a printed appeal for the inclosure of a silver half-dollar, and a prepaid return envelope, has already been practiced with unsatisfactory result. Perhaps personal letters to every medical practitioner in the Section of the several members of the committee, inclosing an appeal for contribution, and a prepaid envelope addressed to the secretary of the committee, may bear better fruit, but the immediate expense of printing and distribution will have to be borne by the Association upon vouchers certified by the chairman and secretary of the committee, the sums thus advanced to be subsequently refunded annually from the amounts thus collected.

After the reading of the report, Drs. Henry D. Holton, W. H. Daly and John A. Wyeth made eloquent appeals for subscriptions looking toward the erection of the monument, and a number of members subscribed various sums.

DR. HOLTON then moved that the report be accepted, and that the thanks of the Association be tendered to the Committee for its work. Seconded.

DR. I. N. QUIMBY, of New Jersey, moved, as an amendment, which was accepted, that the report be published in the JOURNAL. Carried.

DR. J. W. HOFF moved that each delegate to the Association be appointed a committee to collect funds for the Rush Monument from their fellow practitioners and transfer the amounts to the Treasurer of the Committee on Rush Monument at as early a day as practicable. Seconded and carried.

The President then called for the reading of the Report of the Permanent Secretary. The report was read, and is as follows:

#### REPORT OF THE PERMANENT SECRETARY.

*Gentlemen:*—In obedience to the instructions adopted at your last meeting, the inclosed circular was sent to the several State medical societies, and also to each county or district society known to be in affiliation with these. As yet, I have to receive replies from a number, but I have been able to obtain sufficient data to report quite fully on that part relating to the first resolution. There appears to be a general awakening in nearly every State, and several have set on foot earnest efforts to increase not only the membership of the State body, but to produce an improvement in that line in the respective local societies. Notably I may mention Pennsylvania, which has appointed a committee to attend to this matter, and already two societies have been revived and made efficient, and many others have much increased their membership. The interests of the American Medical Association have also been kept in sight, and all who were not connected with it have been urged to join.

In the matter of arranging the dates of meeting so as not to interfere with the meetings of this Association, nothing has yet been done, though I have addressed a second communication in certain instances urging attention to this and to the subject of "a uniform standard of professional requirement for admission to the practice of medicine and to aid as far as possible, in advancing the scientific status of the same by the appointment of State Examining Boards, independent of the teaching faculties of the medical colleges." I hope next year to report that action has been taken at least by some on this very important matter.

The several State medical societies through their secretaries have furnished me the following information:

Alabama: An auxiliary society in every county in the State, 66. Generally the best men in the county are mem-

bers. Membership in the county society constitutes membership in the State association. In all, 1,067 members.

Illinois: Membership 695.

Idaho: Membership 35.

Iowa: Membership, 600. Fayette County, 34; Cherokee County, 22; Clinton County, 34; Washington County, 22; Southwest Iowa, 58; Harrison County, 7; Dubuque Medical, 30; Cedar Valley Medical, 139; Council Bluffs Medical, 19; Botna Valley Medical, 31; Wapello County, 26; Story County, 17; Medical Association N. W. Iowa, 33; Big 4 ("Four"), 41; Warren, 15; North Iowa Medical, 30; H. and S. Medical, 9; Iowa Central, 30; Lyon County, 13; Central District, 49; Jackson County, 14.

Kentucky: Membership 455.

Louisiana: Membership 386.

Maryland: Membership 456.

Massachusetts: 2,000. Barnstable District Medical, 25; Berkshire, 50; Bristol North, 40; Bristol South, 60; Essex North, 80; Essex South, 120; Franklin, 25; Hampden, 90; Hampshire, 40; Middlesex East, 40; Middlesex North, 90; Middlesex South, 245; Norfolk, 210; Norfolk South, 25; Plymouth, 50; Suffolk, 470; Worcester, 130; Worcester North, 40.

New Hampshire: Membership 290.

New York: (State Medical Association). King's County, 100.

North Dakota: Membership 200. Cass County, 25.

Pennsylvania: Membership, 1,300. Allegheny County, 200; Armstrong, 21; Beaver, 30; Berks, 50; Blair, 52; Bradford, 21; Bucks, 41; Butler, 33; Cambria, 34; Carbon, 19; Centre, 23; Chester, 31; Clarion, 24; Clearfield, 23; Clinton, 24; Columbia, 20; Crawford, 22; Cumberland, 23; Dauphin, 43; Delaware, 36; Elk, 16; Erie, 30; Fayette, 44; Franklin, 31; Greene, 13; Huntingdon, 18; Indiana, 17; Jefferson, 35; Lackawanna, 49; Lancaster, 92; Lawrence, 16; Lebanon, 13; Lehigh, 34; Luzerne, 73; Lycoming, 57; McKean, 11; Mercer, 28; Mifflin, 16; Montgomery, 56; Montour, 15; Northampton, 51; Northumberland, 31; Perry, 22; Philadelphia, 639; Schuylkill, 58; Somerset, 24; Susquehanna, 30; Venango, 32; Warren, 26; Wayne, 18; Westmoreland, 67; Work, 31; Washington, 40.

Rhode Island: Membership 248.

Vermont: Membership 192.

Wisconsin: Membership 400.

District of Columbia: Membership 370.

Arizona: Membership 40; Mariposa County, 20; Yavapai County, 10.

In addition to the replies received from the State societies, a large number of county or district societies have sent me very full reports. Several of these appear to have taken hold of this subject with enthusiasm, and are determined to enroll in their ranks every eligible member of the profession practicing in their bounds.

The following States have the county or district societies in affiliation:

Alabama, full list of societies; Arkansas, only partial list; California, 20 counties; Colorado, 9 counties; Connecticut, 8 counties; Illinois, 50 local societies; Indiana, 70 counties; Iowa, 21 county and district; Kansas, 1 district; Kentucky, no list; Maryland, 3 districts; Massachusetts, 18 districts; Michigan, 20 districts; Minnesota, 3 counties; Montana, 1 district; Nebraska, 15 districts; New Jersey, 21 counties; New York, 2 counties; Ohio, 54 districts; Pennsylvania, 54 counties; this State has 2,500 members in affiliation; South Carolina, 6 counties. Of none of these have I been able to secure anything certain; Tennessee, no information, though I am assured that a number of district societies are in affiliation; Texas, 30 districts are reported, but only a few have replied to my inquiry; Utah, no State body, 2 district societies; West Virginia, 1 society.

The following States have only State medical societies. Any local societies that may exist are not in any way connected with the State society:

Delaware, Florida, Georgia, Idaho, Louisiana, Maine, Mississippi, Missouri, Nevada, New Hampshire, New Mexico, North Carolina, Oregon, Rhode Island, South Dakota, Vermont, Virginia, Washington, Wisconsin.

In addition, the Territories of Arizona, Indian and Oklahoma have Territorial societies. Medical Association of the District of Columbia.

Should a future report of this nature be demanded, I hope to be able to give the membership in numbers of each State body, and with it the number of eligible physicians in each State.

Respectfully, W. B. ATKINSON, M.D.

On motion of Dr. Quimby, the report was accepted.

THE PRESIDENT—We will now listen to the report of the Treasurer.

The Treasurer, Dr. Henry P. Newman, of Chicago, then read his report as follows:

# TREASURER'S REPORT.

In submitting my first annual report as the Treasurer of the American Medical Association, I desire to offer a word of explanation in regard to some matters which have, perhaps, been less satisfactory than could be desired, and a word of suggestion as to the furtherance of our mutual interests.

At the time of my election, last June, the business pertaining to this office came at once into my hands, while I did not receive the books of the former incumbent until two months afterward. This delay created so much confusion in matters of record and book-keeping that it was found impossible to reduce the office work to a system immediately. And when the books were received, the task of comparison and revision, augmented by the ever increasing current work, became very onerous and required careful personal attention supplemented by the aid of a clerical expert to bring about a smooth adjustment of our running gear.

It is now generally known that the office of the Treasurer has been moved to Chicago and there should be no more cause to complain of the carelessness of members continuing to send in their dues to Philadelphia, causing the former Treasurer unnecessary labor and annoyance, and more or less confusion in their individual accounts.

The clerical difficulties arising out of these conditions are lessening with the passing of the year, and with the adoption of a new method and the cooperation of the members will soon be impossible altogether.

Having made the financial interest of the Association a careful study since my incumbency and endeavored to reduce the business of the office to as practical, accurate and economical a basis as is possible, I have these suggestions to make with the view of simplifying our methods, and at the same time attaining the greatest possible efficiency.

In the first place, I would strongly urge upon the Association the expediency and the necessity of changing the fiscal year, which now runs from June to May, or May to June, shifting according as the meeting is held in the North or South, to coincide with the calendar year, subscriptions running in future from January to December inclusive.

Many members who have paid toward the close of the past year, (in March or April), their subscriptions being past due, make the quite natural mistake of supposing that they are paying for 1895-96.

This necessitates much correspondence and some misunderstanding on the part of individuals, and I feel sure that a change of the fiscal year would result in nothing but benefit to the Association.

The next suggestion has in view the abrogation of the so-called "three-year rule," by which members are kept in good standing two years after their subscriptions have expired. This is no doubt with generous and kindly intention, but it is manifestly unfair to those who pay annually and whose contributions support the institution with all its benefits and privileges.

There are always in any body of men the few who would be inclined to take advantage of such lenience, and in the minds of such there seems to be an impression that the dues of this Association are payable only once in three years.

In conclusion, I would congratulate the Association upon the excellent financial showing of the past year, the receipts being for the eleven months proportionately greater than those of any other year, notwithstanding the small meeting at San Francisco.

This surplus has been, I believe, judiciously expended in the better equipment of our representative JOURNAL which is fast becoming one of the leading publications of the medical world, and to the circulation of which, and to the efforts of its able Editor, the growing success of the Association is largely due.

Respectfully submitted.

DR. H. P. NEWMAN, Treasurer, in account with the American Medical Association.

Approved by the Auditing Committee.

On motion, the report was accepted.

The Business Committee presented the following:

To the American Medical Association:—Recognizing that one of the main functions of the General Business Committee, as defined in the By-Law creating it, is "to promote the welfare of the Sections," your Committee took under consideration the proposed amendment to Article 11 of the By-Laws, relating to the creation of a Section on Orthopedic Surgery.

After a full and careful consideration of the matter the following resolution was adopted:

Resolved, "That in the opinion of the General Business Committee, the organization of a Section devoted to Orthopedics is not expedient."

Signed, L. D. BULKLEY, Secretary.

On motion the report was adopted.

The Permanent Secretary read the following:

## COMMUNICATION FROM THE SECTION ON STATE MEDICINE.

BALTIMORE, MD., May 7, 1895.

To the President and Members of the American Medical Association:—The following suggestion embodied in the address of the Chairman, Dr. Liston H. Montgomery, read before this Section this afternoon, was upon motion unanimously adopted, and referred to the General Session of the Association with the request that it be read there, and that similar action be taken regarding the appropriation as follows:

"Permit me to suggest that we advise and recommend to the Association in General Session, ere its final adjournment, that the perpetuity of the Special Committee appointed by the American Medical Association, be continued, to memorialize Congress to establish another branch of the Federal Government, to be known as the Department of Public Health with a Medical Secretary of same. That this committee be clothed with additional substantial authority and with the request also from this Section that sufficient financial aid from the Treasury of the Association be appropriated, which should not be less than \$1,000 for the ensuing two years to defray the necessary expenses of the said committee."

Very respectfully submitted,  
CHAS. H. SHEPARD, M.D., Secretary.

It was moved and seconded that the report be referred to the Business Committee.

DR. JOHN B. HAMILTON—Mr. President, I move to amend that motion, that so much of the resolution as refers to an appropriation be referred to the Board of Trustees. Seconded.

DR. CONNOR—I think this matter ought to be referred to the Business Committee for consideration in a deliberate manner; then the Association can better understand what to do with it.

DR. DUDLEY S. REYNOLDS, of Kentucky—I move as a substitute, that the report or suggestion contained in the address of the Chairman on State Medicine be referred back to the Section to formulate something more definite for our consideration. Seconded.

DR. LISTON H. MONTGOMERY, of Chicago—I move that the substitute be laid upon the table. Seconded and carried.

The original motion of Dr. Hamilton was then put by the President and carried.

On motion of Dr. E. F. Wilson, of Ohio, it was unanimously

*Resolved*, That this Association most respectfully appeals to the colleges of the country to at once carry into execution the provisions of the four years curricula of study. Be it further

*Resolved*, That we deplore the efforts being made to amend the rules governing the curricula of study in the Association of American Medical Colleges looking to the defeat of the present requirements governing the granting of degrees.

DR. WM. E. QUINE, of Chicago, then delivered the "Address in Medicine."

On motion of Dr. E. S. Talbot, of Chicago, the following were elected members by invitation: Drs. S. A. Hopkins, Boston, Mass.; J. G. Humsen, Baltimore, Md.; W. A. Miles, W. S. Twilley, Jos. Roach and W. J. Waters, of Baltimore.

An invitation was read from the Mississippi Valley Medical Association to attend their session at Detroit, Michigan, in September 3-6, 1895.

On motion, the Association adjourned until Thursday morning, 10 o'clock.

#### MAY 9—THIRD GENERAL SESSION.

The Association was called to order by the President at 10:30 A.M.

MR. THOMPSON, Chairman of the American Pharmaceutical Association, was invited to a seat on the platform.

The Permanent Secretary read the following from the Judicial Council:

BALTIMORE, May 9, 1895.

#### DECISIONS OF JUDICIAL COUNCIL.

The protest of members of the Allegheny County Medical Society of Pennsylvania against the registration of a former member of that society and the appeal of said member against the decision of the Allegheny County Medical Society is referred to the Medical Society of the State of Pennsylvania for adjudication, with privilege of appeal to the Judicial Council of the American Medical Association after said adjudication.

The protest against registration of members of the Cleveland Medical Society is referred to the Ohio State Medical Society for adjudication; the applications for registration are to remain suspended until the case has been adjudicated by the Ohio State Medical Society, and if any member of the Cleveland Medical Society has already been allowed to register his money is to be refunded.

The charges and protest against a physician of St. Louis are not in proper form to come before the Association.

JOHN B. ROBERTS, Secretary of Judicial Council.

The Permanent Secretary began to read the minutes of Wednesday, when Dr. Holton arose and moved that further reading of them be dispensed with. Carried.

DR. E. E. MONTGOMERY, of Philadelphia, read the report of the Board of Trustees.

#### REPORT OF THE BOARD OF TRUSTEES.

BALTIMORE, May 8, 1895.

Mr. President:—The Trustees in presenting their Annual Report, have the honor to direct your attention to the fact that it covers but eleven months, as the meeting of last year was in June.

The receipts from all sources have been . . . . . \$36,245.90  
The expenditures were . . . . . 30,584.82

Leaving a balance on hand of . . . . . 5,361.08

The receipts of the JOURNAL have been:

From advertising . . . . . \$12,545.91  
From subscriptions . . . . . 1,569.75  
From reprints . . . . . 1,674.67  
From cash sales . . . . . 203.21  
From Ins. paid on account of fire . . . . . 579.00

\$16,572.54

Expenditures—By cash, H. P. Newman . . . . . \$16,009.04  
" " Deposit in bank . . . . . 452.77  
" " Expense . . . . . 88.23  
Balance in Office . . . . . 22.50

\$16,572.54

Expenditures by Treasurer . . . . . 29,344.97  
Cost of the JOURNAL to the Association . . . . . 12,772.43

Of this amount \$6,291.24 was expended for new machinery. The JOURNAL now possesses a plant worth about \$10,000.

The Trustees consider the success of the JOURNAL during the monetary depression of the past two years as a subject upon which you should be congratulated. The JOURNAL contains more reading matter than any similar publication in this country.

The favorable outlook for the future, has led the Trustees

to institute measures for the immediate improvement of the JOURNAL through more frequent illustrations and the extension of its editorial scope. The Trustees confidently assert that none of its contemporaries present advertising pages that are as free from objectionable material.

During the year no advertisements of secret remedies have been accepted that were not accompanied by a formula, but to still further comply with what appears to be the desire of a large number of those interested in the highest success of the JOURNAL, the Editor, with the termination of present contracts, has been instructed to accept no advertisements of medicinal preparations, the proprietors of which do not give a formula containing the official or chemie name and quantity of each composing ingredient to be inserted as a part of the advertisement.

The work of the office was greatly discommoded by a fire March 31, the money loss from which has been fully covered by insurance.

The Trustees respectfully recommend that the fiscal year of the Treasurer and the JOURNAL be made to correspond with the calendar year, believing the adoption of such plan will greatly simplify the keeping of the accounts and better enable them to make yearly comparisons. Now, the fiscal year varies from eleven to thirteen months in different years.

In conclusion, the Trustees desire to express their appreciation of the untiring and loyal devotion of the Editor; of the earnest coöperation of the various employees who uncomplainingly have borne the discomforts incident to moving the office, and resulting from the fire which recently occurred in the JOURNAL office. Respectfully submitted,

ALONZO GARCELON, JOHN W. GRAHAM,  
E. FLETCHER INGALS, PERRY H. MILLARD,  
JOSEPH EASTMAN, JOHN ELIOT WOODBRIDGE,  
DAVID W. GRAHAM, E. E. MONTGOMERY.

The report elicited considerable applause during its reading.

THE PRESIDENT—You have heard the report of the Board of Trustees; what will you do with it? Before taking action upon it I have a suggestion to make: This report is a very important one and may require some little time to discuss. We have here this morning the prospects of an excellent address on surgery by Dr. Wheaton, and I fear that if we enter into a discussion of this report many of the members will become tired and leave the hall before the Doctor has a chance to read his address. I know from personal experience that when a man takes the trouble and pains to prepare an address, he likes to have a good audience to listen to him, and I would therefore suggest, with the consent of the Association, that we now hear Dr. Wheaton's address and discuss the report of the Trustees immediately afterward.

DR. SOLIS-COHEN—Mr. President, I object. I do not desire at this time to interfere with, but to facilitate the business of the Association. The Association is to be congratulated, as well as the Trustees, that it can at last stand upon an honest platform. The report deserves our hearty approval. Their work should be emulated. (Applause.) Now we can go forward, when the time arrives, and demand that every other American medical journal shall make its pages clean from the shame of patent medicines, and unless they do this they should not receive the support and subscriptions of the members of the American Medical Association. (Applause.) On behalf of the Pennsylvania delegation, as commissioned by them officially, and unofficially on behalf of the hundreds of members who came to me, as well as of various medical societies, to express their desire that we go forward to cleanse the JOURNAL, I move the approval of the report of the Board of Trustees. (Applause.) Seconded and unanimously carried.

DR. C. A. WHEATON, of Minnesota, then delivered the "Address on Surgery."

On motion, a vote of thanks was extended to Dr. Wheaton for his able address.

DR. W. C. SPALDING, of New York City, offered the following:

Mr. President and Members of the Association:—With the object of increasing the bond of fellowship that already exists in this honorable body, increasing its scientific advancement, and as an incentive to larger membership, the reader has been thinking seriously as to what course we might take in order to make our organization more widespread, more attractive and better attended at our annual meetings.

It has occurred to me that if this honorable body would give its attention to the question of increase and growth, that we can very greatly add to our numbers and, at the

same time, by adopting a comparatively slight increase in our dues put ourselves in such a position that in a few years we may have a local habitation as well as a name, among scientific bodies.

I would like to call the attention of the Association to a plan to which I have given considerable thought, thinking that if carried out it would surely add to our prestige as a body, our good fellowship as a fraternity, our opportunity for clinical and other scientific demonstration.

This plan is to increase the annual dues of each member \$1, which is to go to a purchasing and building fund to be kept until it has reached an amount large enough to purchase the site, as may be agreed upon by this body, when it shall have reached a sufficient amount for a payment upon or a complete purchase of such location as this body by its vote shall determine. What we desire is a fine National hall of our own, to which we may gather annually, with the feeling upon the part of each member that it is ours and is our home to which we shall all gather yearly, and perhaps as the years roll by we may consider the advisability of establishing in connection with it a place of comfort and rest for those of our profession who in giving to others have robbed themselves of the fruits that should have blest their old age, those whose faculties have been dimmed through hard pursuit of relief to suffering humanity, and those who by disease and accident have been disabled from further pursuing their chosen profession, but who in all honorable means have endeavored to advance the cause of scientific healing of their fellow men.

DR. B. B. GODFREY, of Michigan, in accordance with the above, offered the following:

In reference to the foregoing resolution I make the following motion:

That the members of the Association raise their annual assessment \$1, for the purpose of creating a building fund; that the President be hereby empowered to appoint a committee consisting of one permanent member from each State and territory represented in this Association, whose duty shall be to solicit subscriptions to this fund, and act as an advisory board to the trustees of this Association, in reference to the investment of the fund as it shall accumulate. That the President shall appoint the committee in the following manner: as nearly as possible one-third for one year, one-third for two years and one-third for three years, and at the expiration of their terms their successors be appointed for three years. This committee shall report at each annual meeting of the Association the amount of the subscriptions received in their respective territory.

DR. X. C. SCOTT, of Ohio—I move that the matter to which we have just listened be laid over until next year, inasmuch as it is virtually changing the By-Laws of the Association. Seconded.

DR. P. H. MILLARD, of Minnesota—I move, as a substitute, that the whole matter be indefinitely postponed. This Association is the representative body of the profession of America. We have entirely too many associations at the present time and to raise funds for the purpose outlined is not practicable. It is the duty of this Association to father its JOURNAL, to build it up. It is the greatest journal of the Western continent to-day. (Applause.) Its Trustees have been making a struggle financially to put both the JOURNAL and the Association upon their feet, and we desire adequate financial support. The moment we divert funds for the purpose named it will be a sad day so far as the future usefulness of the JOURNAL is concerned. (Applause.)

DR. JOHN B. ROBERTS, of Philadelphia—I move to amend Dr. Millard's resolution, that it be referred to the Business Committee. Seconded and carried.

DR. A. KOENIG, of Pittsburgh—The Board of Trustees having cleansed the JOURNAL of secret advertisements, I rise to move a vote of confidence in the Trustees for their action in now eliminating objectionable advertisements from the pages of the JOURNAL. Long may they live. (Applause.) Seconded.

DR. JOHN B. HAMILTON, of Chicago—I think it is unfair to allow the statement that has just been made to go on record without a little correction and explanation. The question decided on Monday was not a question of approval or disapproval of the Trustees, but whether they should be forced to make a report or not, and whether a committee should be appointed over them, and it is hardly fair to imply that the Association one day approves an act of the Board of Trustees, and then on the next day approves another act of a different kind. The vote of confidence was passed on Monday and again to-day when its report was adopted. I therefore make a motion to reconsider. Seconded.

THE PRESIDENT—If the Association has already voted its good will and confidence in the Board of Trustees, it seems to me it is all that is necessary.

DR. KOENIG—The Association can scarcely go on record as not approving the action of the Board of Trustees.

DR. JEROME COCHRAN, of Alabama—I rise to a question of personal privilege in regard to this matter. The gentleman, who offered the last motion, seems to have had my speech in mind when he made it. When I spoke on a previous occasion, it was not my object to eulogize the action of the Board of Trustees in eliminating the advertisements of private remedies, but to vindicate the Trustees themselves; to have this Association assert that they had placed the matter in the hands of the Trustees; that they were willing to trust the Board of Trustees; that they did not require to have guardians appointed for their guidance in this matter. That was the object of the speech I made. (Applause.)

DR. KOENIG—Three years ago in Detroit the Board of Trustees were requested to exclude objectionable advertisements from the pages of the JOURNAL. They did not do it. Now they have done it. The other day a statement was made that no other journal in the country excluded these advertisements. I know to the contrary, and the journals live, and why should not the JOURNAL be an ideal one, representing the best element of the profession of this country, by excluding quack advertisements from its pages. We do not need their filthy money. We do not want it. (Loud applause.)

On motion of Dr. Cohen, the motion to reconsider was tabled without objection.

DR. E. D. FERGUSON, of Troy, N. Y.—I rise to request a ruling from the Chair on matters that may come before the Association under the head of Miscellaneous Business. It is with reference to amendments to the Constitution and By-Laws, as printed on pages 8 and 9 of the program. (The following are the amendments referred to):

#### AMENDMENTS TO THE CONSTITUTION AND BY-LAWS.

(Offered in previous years and laid over from 1893 and 1894.)

Offered by DR. C. A. L. REED:

Amend Article I, Section 1, of the Regulations, by inserting after the words United States, the words "The Dominion of Canada, Labrador and Newfoundland," and that such other changes be made in the phraseology of the Regulations and By-Laws as to make the same conform to this contemplated enlarged jurisdiction of the Association.

By DR. I. N. QUIMBY:

"That Thursday morning's General Session be omitted, and the time be devoted to Sectional work."

By DRS. JOHN MORRIS and J. G. KIERNAN:

Amend Section 7 of the Constitution entitled, "The General Business Committee," as follows: "It shall be the future duty of the General Business Committee to make and present the nominations for the officers of the Association and its Standing Committees, and recommend the time and place for the meeting of the Association."

"The General Business Committee of the Association shall perform all duties hitherto performed by the Committee on Nominations, which is hereby abolished. All sections of the Constitution and By-Laws, or parts thereof, inconsistent with the amendment are hereby repealed."

By DR. F. F. DOW:

Amend By-Law No. XI, relating to the Judicial Council. The second clause of paragraph 3 shall be amended to read as follows: "The decisions of said Council on all matters referred to it by the Association shall be reported at the earliest practicable moment, and shall be final unless revised by the Association."

By DR. A. B. HOSMER:

"WHEREAS, The constantly increasing number of papers on general surgical subjects presented each year at the Surgical Section of this Association, the reading and even restricted discussion of which prohibit the introduction of any considerable number of papers on strictly orthopedic subjects, which might not prove of universal interest to the general surgeon; and

"WHEREAS, There are already a sufficient and rapidly increasing number of members of the Surgical Section of this Association especially interested in this branch of surgery to warrant it; therefore be it

"Resolved, To amend Article II, of the By-Laws, by the addition under the heading Sections, and after 12, Physiology and Dietetics, the following: 13, Orthopedic Surgery."

By DR. F. F. DOW:

Amendment to the Constitution, to be known as Article VIII, entitled "The Code of Ethics:"

"The relations of the physician to the patient, to the public, and to the profession require that he shall be of good moral character, and in his personal and professional conduct without reproach; that he shall avoid pretense and notoriety; that he shall properly qualify himself for professional duty by broad and liberal studies in letters, sciences and arts; that he shall employ reasonable and reputable methods of practice; that he shall respect the laws of the State; that he shall encourage efficient means for the enlightenment of public opinion regarding the responsibilities of medical men and the relation of the citizen to public health, for the cultivation of medical education, for the promotion of the interests, usefulness, and honor of the profession, for the emulation, concerted action, and friendly intercourse among those engaged in it.

"Substituting the Roman numerals IX for VIII.

"All Articles, By-Laws, and Codes inconsistent with this amendment are hereby repealed."

By DR. J. H. RAUCH:

"That on and after July 1, 1897, no one will be admitted to membership in the American Medical Association who has not studied medicine for four years, and attended four annual courses of lectures of at least six months' duration."

By DR. J. T. PRIESTLEY:

"The entire report on Constitution, etc., as offered in the report of Dr. Holton at San Francisco."

DR. FERGUSON (resuming)—Before I ask the decision of the Chair in reference to this matter, I desire to make one or two statements concerning the amendments and their history at the San Francisco meeting last year. All of the amendments herewith were before the meeting at that place, and by reference to the heading we will find some of them have been laid over since 1893. The amendments were considered at San Francisco, were handled in the various parliamentary ways customary in such matters, and after they had been thoroughly considered and had been acted upon negatively, a final motion was made that all of the amendments to the Constitution and By-Laws and Code of Ethics be indefinitely postponed. Whether any one of these had been up or not at that meeting, the resolution to that effect was broad enough to cover all. Some of the resolutions are entirely impracticable, particularly the one introduced by Dr. Rauch, which would prohibit a large majority of the profession from membership in the Association; that if they should happen to fall out of membership, it would prevent them from ever getting back into it again. In order to simplify matters, I ask for your ruling, sir, as to whether all of these amendments to the Constitution and By-Laws down to the last one (Dr. Priestley's) are not properly before the Association.

THE PRESIDENT—My opinion is that they are not proper subjects for consideration here in the present state of affairs. The course of the Association with regard to them before made it, if not absolutely unparliamentary, at all events, so entirely unwise that it seems to me best to take that course in the matter, and I therefore rule (with the exception of Dr. Priestley's amendment) that they are not proper subjects for discussion at the present time.

DR. COCHRAN—On what different basis does the last amendment stand?

DR. FERGUSON—I am going to explain that. The last amendment, Mr. President, is rather peculiar. It is an amendment to the Constitution, etc., which is extremely indefinite. I know the members of the Association—most of them at least—will recall the whole subject for the last three or four years of our history. It has been incubating since that time. At the San Francisco meeting a large majority of the members voted for indefinite postponement; but we were told from the floor that it was like Banquo's ghost, it would come up and come up, again and again. It would not down. (Laughter.) Some one in the audience at the San Francisco meeting held up his hand, was recognized by the President, and called the attention of the Chair to an amendment to the Constitution. I endeavored to find out what that amendment was. I felt that we ought to know. Some of my neighbors informed me that it was a simple matter; that it had no significance whatever. I went home with that feeling. I read the printed proceedings of the meeting in the JOURNAL, and I had no more light on the subject. Finally, I wrote to the Secretary, and some months after the meeting I found out that the amendment to the Constitution had been but a small slip of paper sent in as the entire report of the committee of which Dr. Holton was Chairman. (Laughter.) Many of you will doubtless recall that that report, as presented at the San Francisco meeting, was not exactly the report as printed in the JOURNAL.

DR. DUDLEY S. REYNOLDS, of Louisville, Ky.—Mr. President, I rise to a point of order.

THE PRESIDENT—The gentleman will please state his point of order.

DR. REYNOLDS—Your entire ruling, sir, is that these amendments are not properly before this meeting, and I hold, sir, that matters not properly before the meeting are not debatable.

THE PRESIDENT—The point is well taken.

DR. REYNOLDS—I now move you, sir, that the amendment offered by Dr. Priestley be indefinitely postponed. Seconded and carried.

DR. COCHRAN—There is another amendment to the Constitution which is not on the program. It belongs to the class of new amendments, and was offered by Dr. Quimby, its object being to strike from the Code of Ethics the clause prohibiting the patenting of surgical instruments. I forget the number of the Section. I move that that amendment be taken up for consideration. Seconded.

DR. N. S. DAVIS, of Chicago—Mr. President, it is certainly with a great deal of reluctance that I ask to be heard for a few moments at this time, not that I regard the subject under consideration of more importance than those that have come before the meeting, but I want to speak a word

or two in regard to what I deem fundamental and essential to the perpetuation, the character, and honor of this Association (applause), which should represent by delegation the profession of this broad country as it was originally designed—a true, representative organization, having in view two grand objects: the promotion of fraternal feeling and social intercourse, and the science and art of medicine. (Loud applause.) These objects and no other advance the science and art of medicine. They carry with them the education of the profession, social intercourse, the mingling and fraternal feeling from all parts of our country, contributing immensely to the status and influence of the profession. Now, in looking over the Transactions and following these meetings from the first convention down to this, with only very few exceptions, almost every year somebody has taken it upon himself to alter our Constitution and By-Laws. He is continually picking up something to find fault with. (Applause.) Now, for heaven's sake we have got a Constitution and By-Laws that provide for a representative body. We have an open door that allows every physician in good standing in his local medical society to become a member—a door broad enough to receive the unanimous indorsement and support of the English-speaking people of the globe. (Applause.) Our Association is founded on the same principle as that of the British Medical Association. No man, who has discovered anything of value as a remedial agent, is allowed to keep it secret. If it is a medicine calculated to do good to humanity, he has to make it known freely to his professional brethren and to the world. (Applause.) Again, if any man devises an instrument that is useful for surgical or other purposes, it is his business to let his brethren know about it. There should be no secrets. (Applause.) It is the province of the physician to alleviate human suffering. I have arisen, Mr. President, to move that all of the amendments to the Constitution and By-Laws referred to be indefinitely postponed. Seconded and carried by a large majority.

Here Dr. J. T. PRIESTLEY arose and offered a new amendment containing some of the same amendments which had been previously disposed of by the Association.

DR. X. C. SCOTT—I rise to a point of order in reference to the amendment just presented. By previous action of the Association all amendments to the Constitution and By-Laws have been indefinitely postponed, and hence no one of those amendments can be re-introduced at this meeting. That sir, is my point of order.

THE PRESIDENT—My ruling is that inasmuch as action has already been taken in regard to the various amendments, they can not be re-introduced at this meeting.

DR. JOHN B. ROBERTS—There is a point here that most of the members do not understand. It is the privilege of every member of the Association, the youngest as well as the oldest, to introduce at any time an amendment to the Constitution, and I, sir, appeal from the decision of the Chair. If I understand the matter correctly, the decision of the Chair is that these amendments can not be brought forward at this time. I will ask the President to state his reasons for such a ruling, and then I will present mine, and then we can vote upon whether the opinion of the Chair shall be sustained.

DR. N. S. DAVIS—I wish to call attention to what seems to me an important point in regard to offering amendments. The habit has grown up of late which seems to imply that anybody has a right to propose an amendment to the Constitution and By-Laws. These amendments are given to the officers, and are then laid over. Nobody knows what they are. Now, my own idea is that no one has a right to propose an amendment to the Constitution, unless that amendment is written out clearly, plainly stating the sections he proposes to amend, and after it is proposed it should be stated from the Chair definitely, who shall ask for a vote to either accept it or to lay it on the table.

DR. W. H. DALY, of Pittsburgh—I concur with Dr. Davis that it is not right for amendments to be laid over to incubate for a year without knowing what they are. The proper way, it seems to me, is to read them and then lay them over.

THE PRESIDENT—I have no objections to the amendments, but when you have voted to indefinitely postpone them, and then move to re-consider the subject, it strikes me as a rather peculiar way of treating the matter.

DR. N. S. DAVIS—The only way in which subjects of the same character can be re-introduced at this meeting, after having voted for indefinite postponement, is to move a reconsideration of the vote of postponement, and then we will get that before us.

DR. JAMES F. HIBBERD, of Indiana—My understanding about the parliamentary rule in regard to this matter is this, that if the matter be a series of resolutions and they are laid over, you can take some part or distinct proposition and consider it, but I do not propose to consider what has been indefinitely postponed. I merely desire to state my recollection of the parliamentary law, which, I believe, is just as I have given it.

DR. A. L. GIBON—It is a rule in mathematics that the greater includes the less.

DR. HIBBERD—That may be where you come from. (Laughter.)

DR. I. N. QUIMBY—Any subject that has been indefinitely postponed during this session, or any amendment germane to it, can not be re-introduced at this time.

THE PRESIDENT—I adhere to my original ruling. Dr. Roberts appeals from the decision of the Chair. I will put the motion of appeal.

A MEMBER—I move that the motion to appeal from the decision of the Chair be laid upon the table.

DR. ROBERTS—You can not lay a motion to appeal on the table. If some gentleman here has seen fit to offer an amendment to the Constitution, I claim that he has a right to be heard, a right to have it read, and then laid over. No President has a right to shut off any member. We can protect him by appealing from the decision of the Chair. The Chair must then state his reasons, and the gentleman who offers the amendment or amendments must also state his objections to the ruling of the Chair. The Chair must then state to the Association, "Shall the Chair be sustained?" It is certainly an unjustifiable proceeding to shut off any man from introducing an amendment to the Constitution which is to lie over. He has a right to have it read, to have it spread upon the minutes, and no President has authority to shut him off. (Applause.)

PRESIDENT MACLEAN then put the motion of appeal, and the Chair was sustained.

THE PRESIDENT—I endeavor to give the members of the Association every possible privilege, and I shall do my best to protect them. If any amendments are to be introduced, they shall be read from the stage and laid over, and voted on at the next meeting. But, gentlemen, I do object to resolutions or amendments being quietly introduced and then laid over as a trap for my successor. (Applause, and cries of That's right!)

The Section on Obstetrics and Diseases of Women reported the following named officers for the ensuing year: Chairman, J. Tabor Johnson, Washington, D.C.; Secretary, Renben Peterson, Grand Rapids, Mich.

The Section on Physiology and Dietetics reported the following named officers for the ensuing year: Chairman, H. Bert Ellis, of Los Angeles, Cal.; Secretary, Henry Salzer, Baltimore, Secretary.

The Section on Dermatology and Syphilography reported the following named officers for the ensuing year: Chairman, L. Duncan Bulkley, New York City; Secretary, T. C. Gilchrist, Baltimore, Md.; Executive Committee, L. A. Duhring, Philadelphia, Pa.; A. H. Ohmann-Dumesnil, St. Louis, Mo.; A. E. Regensberger, San Francisco, Cal.

The Section on State Medicine reported the following named officers for the ensuing year: Chairman, Charles H. Shepard, Brooklyn, N.Y.; Secretary, Elmer Lee, Chicago, Ill.; Executive Committee: for one year, C. A. Lindsley, New Haven, Conn.; for two years, G. W. Stoner, U. S. M.-H., Baltimore, Md.; three years, L. H. Montgomery, Chicago, Ill.

The Section on Neurology and Medical Jurisprudence reported the following named officers for the ensuing year: Chairman, T. D. Crothers, Hartford, Conn.; Secretary, W. J. Herdman, Ann Arbor, Mich.; Executive Committee, Daniel R. Brower, Chicago, Ill.; W. N. Sudduth, Minneapolis, Minn.; W. S. Watson, Fishkill, N. Y.

The Section on Dental and Oral Surgery reported the following officers for the ensuing year: Chairman, R. R. Andrews, Cambridge, Mass.; Secretary, Eugene S. Talbot, Chicago, Ill.; Executive Committee, M. E. Fletcher, Cincinnati, Ohio; Eugene S. Talbot, Chicago, Ill.; A. E. Baldwin, Chicago, Ill.

DR. JEROME COCHRAN, Chairman of the Committee on Secretary of Public Health, reported as follows:

To the President of the American Medical Association:—After the elaborate report made by this Committee at San Francisco last year, our report for the present year need not be very extensive, and we beg to report briefly as follows:

1. Our facilities for doing the important work intrusted to us have been strictly limited by want of funds, the Association having failed to adopt the resolution offered last year

for an appropriation not to exceed four hundred (\$400) dollars to defray the necessary expenses of the committee, so that such expenses as we have incurred have been paid out of our own pockets.

2. In November we addressed a communication to the officers of State and other medical societies and associations urging them to appeal to the members of their respective organizations to write to their members of Congress in both Houses, requesting them to give their support and their votes in aid of the passage of our bill. To this communication we received very few responses. But it was published in a considerable number of medical and sanitary periodicals, and doubtless accomplished some good. A considerable number of medical and sanitary periodicals also published editorial articles in advocacy of the proposed legislation, and these articles have attracted more or less favorable attention among the members of the profession, and have led some of them to appeal to their members of Congress; but not to such general concert of action by the whole body of the profession as we have desired.

3. In December, some members of the committee visited Washington City for the purpose of ascertaining just what could be done toward pushing our enterprise to a successful result. We found a good many members of Congress who promised us their cooperation whenever a favorable time could be found for the consideration of our bill; but all agreed that it would be impossible to accomplish anything during the continuance of the LIII Congress.

4. It is evident from this brief review of the situation, that to secure the passage of our bill to create a Department and Secretary of Public Health, much vigorous work will be required, and in order that this work may be done it will be necessary for the Association to place at the disposal of the committee an adequate amount of money for current expenses. We will have to do a considerable amount of printing. We will have to enlist the active assistance and cooperation of all the State and municipal medical societies. We will have to keep up a very extended correspondence. We will have to enlist the active assistance of the medical and sanitary periodicals of the country. Sometimes, for perhaps months at a time, we will need the services of a competent clerk. It is for the Association to say whether it is prepared for an effort of this magnitude.

To this end we had prepared a resolution recommending an appropriation, but as this object has been accomplished by the action of the Association on the recommendation of the Section on State Medicine, it is not necessary to offer this resolution.

All of which is respectfully submitted.

(Signed by the Committee.)

On motion, the report was received.

DR. J. M. KELLER, of Arkansas—Is there any By-Law as to when the report of the Committee on Nominations shall be made?

THE PRESIDENT—Not to my knowledge.

DR. KELLER—I desire to offer the following resolution:

*Resolved*, That the report of the Nominating Committee shall be made on Thursday morning. I do it for the reason that if we wait until Friday, two-thirds of the delegates will have gone to their homes, and when the report is brought in there are only a few men to vote on it—at least, only a handful of men. Seconded.

DR. DALY—I move that the resolution be referred to the Business Committee.

DR. DAVIS—This proposition is not an alteration of the By-Laws, but simply a resolution as to whether the Committee on Nominations shall report at a definite time each year, and I see no objection to it.

A MEMBER—I would suggest that the mover of the resolution be a little more specific as to time—say after the reading and adoption of the minutes on Thursday morning.

DR. HOLTON—This resolution, if adopted, will cut down our meeting to three days instead of four. (Cries of No! No!) The experience of those gentlemen who have been appointed on the Nominating Committee in the past has been that the committee is usually not able to report on Thursday, and the only way to keep members here is to keep them in suspense, to know whether they have got any office or not.

DR. L. D. BULKLEY—Mr. President, I rise to a point of order. All new matter should be referred to the Business Committee, and their action is to be revised or concurred in by the Association. The Business Committee meets daily to consider matters that come before it. If this resolution is referred to the Business Committee, we can report to-morrow morning.

DR. KELLER—I hope in the future the Nominating Com-

mittee will make its report when most of the delegates are present, and not wait until Friday when a large number have gone to their homes.

DR. QUIMBY—This is a resolution that justly and legitimately belongs to the Business Committee. It is simple in its nature; therefore it is not necessary to go through the red tape to send it to the Business Committee, the Judicial Council, or any other place. The Nominating Committee could have reported this morning.

DR. REYNOLDS—I hope, sir, that you will not rule that the Nominating Committee can not report when it has already completed its deliberations and is ready to do so. I know by precedent, sir, that in former years this committee has made its reports on Thursday morning. We have no law prescribing just what day the committee shall report. I hope, therefore, as the committee is ready to report, that there will be no objections to hearing the report now. (Applause.)

DR. HIBBERD—I move the Committee on Nominations be instructed to report "instantly." Seconded.

DR. BULKLEY—I insist, Mr. President, that this matter should come before the Business Committee as prescribed in our By-Laws.

DR. REYNOLDS—This resolution provides for the future conduct of the Nominating Committee, and Dr. Hibberd's motion is the one I insist upon. We want the committee to report now.

DR. E. JACKSON, of Pennsylvania, asked if the whole thing was not out of order and demanded the ruling of the Chair.

THE PRESIDENT—It is not compulsory that this matter be referred to the Business Committee.

Again, Dr. Bulkley rose to a point of order.

So many motions had been offered that Dr. Cohen asked what was in order, to which the President replied, Dr. Hibberd's motion.

DR. COCHRAN—I think I can offer a solution of the whole trouble. Let the resolution of Dr. Keller with regard to the future action come under the rules of the Business Committee, but that does not preclude the report of the Committee on Nominations being made at this time.

DR. KELLER—I am satisfied to have that done.

The Committee was then asked to report, but the Chairman not being present, no further action was taken.

A report from Dr. J. M. Toner, of Washington, D. C., as Chairman of the Jenner Vaccination Centennial, offering his resignation was read, as follows:

WASHINGTON, D. C., May 8, 1895.

To the President of the American Medical Association:

Dear Doctor:—Owing to continued poor health which renders me incapable of attending efficiently to the duties devolving upon the chairman of the committee of this body, authorized to provide a suitable program of exercises, occupying one day of the session of the meeting of the Association resolved to be held in Washington City in 1896, so as to appropriately celebrate the centennial of Dr. Jenner's discovery, vaccination, I must therefore ask to be excused from this service.

I request this in the interest of this, the most important discovery ever made in medicine, and believing that some more capable chairman will be able to make a brilliant success of this undertaking under the auspices of the American Medical Association, I herewith tender my resignation as chairman of the committee and request that some one else be named for the place. The committee as originally constituted was composed of Drs. J. M. Toner, N. S. Davis, T. F. Wood, J. F. Hibberd and H. D. Didama. The decease of Dr. Wood left a vacancy which I was authorized to fill, which I have done by naming Dr. J. S. Billings.

Trusting that the project of providing for the centennial celebration may be carried forward with success, I remain, dear sir, Your most obedient and humble servant,

J. M. TONER, M.D.

DR. N. S. DAVIS—Dr. Toner, as chairman, has given the subject a great deal of attention while his health permitted, and I think it would be well to wait until we hear the report of the Nominating Committee to see whether Washington will be selected as the place of meeting in 1896, as originally agreed upon.

DR. COHEN—If there is any member of the Nominating Committee present, I move that he be privileged to report in part or in full to the Association. (Cries of No! No!)

On motion of Dr. Millard, the Committee on Nominations was requested to report as to the place of meeting.

DR. J. E. REEVES, of Tennessee, announced that Atlanta, Ga., had been agreed upon.

DR. MILLARD then moved that the meeting of 1896 be held in Washington, D. C. Seconded.

DR. KELLER made a speech in behalf of Hot Springs as the next place of meeting; Dr. Gaston one in favor of Atlanta, and Dr. Howe, of New York, urged the selection of Niagara Falls.

After some discussion, participated in by Drs. Gihon and Keller, on motion of Dr. N. S. Davis the whole matter was laid upon the table till the report of the Nominating Committee was made in full.

THE PRESIDENT—Some action should be taken with regard to the communication of Dr. Toner in which he tenders his resignation.

On motion, the resignation was accepted, and the committee empowered to fill the vacancy.

On motion, the Association adjourned.

MAY 10—FOURTH GENERAL SESSION.

The hour for the opening of the session having passed, on motion of Dr. Taneyhill, Maryland, ex-President Dr. N. S. Davis was called to the Chair. The President and Vice-Presidents were all temporarily absent.

The Permanent Secretary began to read the minutes, when, on motion, their further reading was dispensed with.

PRESIDENT MACLEAN now entered and assumed his duties.

DR. HENRY D. HOLTON, of Brattleboro, Vt., read the "Address in State Medicine."

On motion of Dr. JOHN B. HAMILTON, the thanks of the Association were tendered to Dr. Holton for his able address.

DR. JOHN B. HAMILTON offered the following, which was adopted:

*Resolved*, That hereafter, the Permanent Secretary and the Treasurer shall proceed to the place of meeting one day in advance of the opening session, for the purpose of directing and facilitating registration of members and applicants for membership.

DR. OSLER, of Baltimore, offered the following resolution, which was unanimously adopted:

WHEREAS, This Association learns with profound regret that the "Index Medicus" will cease to appear with the current issue, unless very substantial support is immediately given; and

WHEREAS, We recognize the value to our profession of this most complete bibliography and the loss the profession would sustain if it were discontinued; therefore be it

*Resolved*, That this Association urge its members to individually support this publication with a view to its continuance until such time as more permanent provision can be made.

The Committee on Section on Benevolence reported as follows:

Report of the Committee on a proposed American Medical Benevolent Fund, to be raised by a Section of the Association for the benefit of the Widows and Orphans of Deceased Physicians.

Brief reference may be made to undertakings of the kind in the United States and Great Britain whose aim it is to afford prompt and sure pecuniary help to distressed qualified physicians and their families, especially widows and orphans:

British Medical Benevolent Fund. The President of this Association, founded in 1836, is Sir James Paget, F.R.S. A late report furnished by the courtesy of W. H. Broadbent, M.D., Bart., shows that the whole of the money subscribed is available for the objects of the charity for which the British Medical Benevolent Fund is raised—many of them of utter destitution, and the relief given is not unfrequently all that stands between the recipient and the humiliation of accepting parochial relief. The timely aid thus given has enabled the needy ones to look around and find means for the support of themselves and children. Her Majesty Queen Victoria, the British Medical Association, and the Faculty of Physicians and Surgeons contribute to this fund.

The first Medical Benefit Society in America for the relief of destitute physicians or their families was organized in Boston in 1854. The money distributed to beneficiaries amounts to \$9,340, according to Treasurer Dr. Francis Minot's report for 1891.

Next was founded the American Mutual Medical Aid Association of Kentucky, in which an admission fee of \$10, and annual fee of \$2, secures to the family of a deceased member of the society \$2,500, or to one sick, \$5 per week.

In 1875 was founded the New York Physicians' Mutual Aid Society, membership 350. Dr. Blumenthal, a late President of this society, says of the work: "The grief and sorrow assuaged by their benefactions no figures or words can express." Its most faithful supporters are bachelors of the medical profession.

In 1878 was formed the Mutual Aid Society of the Philadelphia County Medical Society. Dr. Benjamin Lee, a late President, says of this society: "It seeks to remove the

reproach from the profession that they alone of all callings and crafts make no systematic provision for the relief of brethren in distress and for their destitute widows and orphans left dependent on the cold charities of the world."

The Medical Aid Society of the State Medical Society of Virginia levies an assessment of \$1 on the occasion of the death of a member, to be paid over to the family of a deceased physician.

These societies hold annual meetings, and require the applicant for aid to give name, date of graduation, college, means of support and cause of pecuniary distress, and in case of death of a Fellow of the Association, the address and application of the widow or orphans certified by two physicians. It may be added, among prominent physicians in the United States who have given their support and money toward the endowment of a Medical Aid Fund may be named many ex-Presidents of the American Medical Association, viz: the late S. W. Gross, Austin Flint Sr., John Hodgkin, and W. T. Briggs, Prof. N. S. Davis Sr., Lewis Sayre, P. O. Hooper, Henry O. Marcy and the eminent gentleman who at present presides over the Association, Donald Maclean, all of whom have officially declared, "that any practical plan to aid disabled physicians and their families deserves the favorable consideration and support of every member of this Association, and they will gladly favor such an object."

In closing this report your committee will venture the opinion, based upon the facts and proofs above given of the success of the Medical Aid Societies of Massachusetts, of Kentucky, Pennsylvania and of other States, that the time has come for this Association to undertake a like good work according as its wisdom may decide. This appeal your committee would make especially to the Christian physicians of the Association who believe that "pure religion and undefiled before God and the Father is this; to visit the fatherless and widows in their affliction"—and, "if any provide not for his own, and especially for those of his own house, he hath denied the faith and is worse than an infidel."

Finally, your committee believes that if a Section on Benevolence be engrafted upon the Association that ere the close of the nineteenth century its membership will be augmented, its fraternity strengthened and other National organizations, such as the American Public Health, the Surgical and Gynecological, and the Military Surgeons' Associations of the United States will become cordial co-workers with us in this godly duty toward the needy ones of our profession.

Respectfully submitted,

FREDERICK HORNER, M.D., Chairman of Com.

On motion of Dr. Jackson, of Pennsylvania, the report was received, and the committee continued, with instructions to report a feasible plan at the next meeting of the Association.

Dr. E. D. FERGUSON, of New York, Secretary of the Committee on Nominations, read the report of that committee, as follows:

#### REPORT OF COMMITTEE ON NOMINATIONS.

The Committee on Nominations met at 3 P.M., on Wednesday, May 8 and organized by the election of Dr. J. E. Reeves as Chairman and Dr. E. D. Ferguson as Secretary.

After some preliminary arrangements concerning the methods of selecting candidates, etc., the following list of candidates was selected:

President, R. Beverly Cole, California.

First Vice-President, J. J. Chisolm, Maryland.

Second Vice-President, C. Le Grand, Alabama.

Third Vice-President, Augustus C. Clarke, Massachusetts.

Fourth Vice-President, T. P. Satterwhite, Kentucky.

Treasurer, Henry P. Newman, Illinois.

Secretary, Frank Woodbury, Pennsylvania.

Librarian, G. E. Wire, Illinois.

Members of the Board of Trustees: Alonzo Garcelon, Maine; I. N. Love, Missouri; James E. Reeves, Tennessee.

Members of the Judicial Council: N. S. Davis, Illinois; H. D. Didama, New York; John Morris, Maryland; W. E. B. Davis, Alabama; Daniel R. Brower, Illinois; D. W. Smouse, Iowa; M. B. Ward, Kansas, for three years. W. M. Welch, Pennsylvania, for one year.

Address in Surgery, Nicholas Senn, Illinois.

Address in Medicine, William Osler, Maryland.

Address in State Medicine, Geo. H. Rohé, Maryland.

Atlanta, Ga., was then selected as the place of meeting for 1896, and W. F. Westmoreland was designated as the Chairman of the Committee of Arrangements and J. McFadden Gaston, Jr., as Assistant Secretary.

JAMES E. REEVES, Chairman.

E. D. FERGUSON, Secretary.

Dr. G. L. TANEYHILL—I move the adoption of all of the

report except that pertaining to the place of meeting and the election of the Secretary.

Dr. GEO. W. WEBSTER, of Chicago—I second the motion. Carried.

Dr. FERGUSON—With regard to the question of election of the Secretary, the point was raised as to whether the committee should have made any nomination at all. There is provision in the Constitution that the Permanent Secretary shall remain in office until, either by death, resignation, or removal, by a two-thirds vote of the Association a change shall take place. Whether it is proper for the Committee on Nominations to bring up that question each year is a question. Personally, I feel that it should not. I therefore move that that portion of the report pertaining to the Permanent Secretary be not agreed to, and that the present incumbent remain in office.

Several members seconded this motion.

Dr. I. N. QUIMBY—I have a few remarks to make, and I do so with reluctance because I know what I say will be a divergence from some of my best friends; but under the present circumstances, taking all the views into consideration of the long, faithful service of our present Secretary, which has been, gentlemen, thirty-one years and without a single absence in all those times (applause); an unprecedented attendant upon our meetings, we ought not as a scientific body to cast him aside. Let us do justice to our faithful hard-working men. (Applause.) I tell you, Mr. President, that this magnificent Association whose foundation stone is principally the advancement of scientific medicine for the healing of the nation, can not afford to do Dr. Atkinson an injustice. It can not afford to do a single member injustice, whether he be high or low. Let the sentiment of this Association be *fiat justitia*—exact justice and mercy to every one, whether he be high or low, and let this Association sustain the present Secretary, at least for the present. Let us not send him home as though he had some affliction, but let us try and make him feel happy. I therefore second the motion that the present Secretary remain in office in the place of the one nominated.

THE PRESIDENT—Are you ready for the question? (Cries of Question! Question!)

Dr. OSLER—*Fiat justitia* for the Association is all right, but let the quality of mercy be not strained. I stand here and say plainly and honestly before Dr. Atkinson what I and many other members have said behind his back, that he is not an efficient Secretary of this Association, and that we have not found him so. (Hisses, followed by applause.) You may hiss if you will, but I unhesitatingly say that no more important step in advance will be taken by this Association than when it changes its Secretary. (Cries of Question! Question!)

PRESIDENT MACLEAN put the motion that the present incumbent remain in office, and it was carried by a large majority.

Dr. I. N. LOVE—It having been determined that this Association has no power to elect its Secretary, I move that the Constitution be amended, so that in future the Secretary shall be elected annually. Seconded.

Dr. PRIESTLEY—That is the point I offered in my resolution yesterday.

Dr. C. W. BROWN, of the District of Columbia, moved to select Washington as the next place of meeting. This motion was supported by Dr. A. L. Gihon.

Dr. JEROME COCHRAN urged Atlanta, Ga. After considerable discussion in which Drs. Gihon, Gaston, Taneyhill, Cochran, Keller, Quimby, Brown, Daly, Bishop, Reynolds, Scott, Davis, Garcelon, and Love participated, Atlanta was agreed to as the next place of meeting.

Dr. H. BERT ELLIS, of California, offered certain resolutions recognizing the members of the profession in New York regardless of their affiliation with the body which had abandoned the Code of Ethics.

Dr. N. S. DAVIS announced that to entertain these resolutions it would be necessary to alter the Constitution.

THE PRESIDENT decided that these resolutions were out of order.

On motion, Drs. Gihon and Ferguson were appointed a Committee to conduct the President-elect to the Chair.

Dr. R. BEVERLY COLE, of San Francisco, was then conducted to the platform and received by the President, amid much applause.

PRESIDENT MACLEAN, in introducing his successor, said: "It gives me great pleasure not only personally but officially to present to you our next President, Dr. R. Beverly Cole, of San Francisco. In doing so I extend to him the heartiest good wishes for his administration in this honorable office,

and I wish to say that if at the next meeting the members of the Association treat him as generously, kindly and nobly as it has the retiring President, he will be a very fortunate, happy and very proud man." (Applause.)

PRESIDENT COLE then addressed the Association as follows: "I apprehend that no man lives but that he at some time in his life has been overtaken by circumstances which paralyze his powers of expression. Such is my position at this moment. Any member would feel proud of being elevated to this exalted position by such a body of men, representing the brains of our profession of the North and South, East and West. The compliment is one that is not only appreciated by my humble self, but my State will feel that it is the handsomest compliment and the proudest day in her history when it shall be wafted across the continent that I have been elevated to this exalted position. (Applause.) In this there is no egotism involved. I am here as the representative of my State and coast. I would not be here otherwise, and then if it be that her representative is elevated to this position, must it not follow that the State herself will feel proud of this compliment as expressed through her humble representative? I want to say here that I am perhaps one of the oldest members of this Association. Many have been the voyages that I have made, that I might mingle with you, from the far-off land where the sun goes down, but leaves the softening influence of its rays upon her people. From that far-off land many have been the voyages I have made at a cost of three months' time. But there was some attraction for me, and I leave it to you to divine what that possible attraction has been. Since our facilities have increased I have attended the meetings almost regularly, with the exception that there was an interruption for four years of my visitations owing to impaired health. Thank God I have been measurably restored, and that an opportunity has been furnished me to return to the fold and to receive this hearty recognition at your hands.

"In my administration I shall endeavor to rule fairly, impartially, but you may depend upon one thing. I will endeavor to understand clearly and intelligently every question as it may be presented and rely upon my intelligence and interpretation of the law in my rulings. But there will be no hesitation. I shall rule firmly, but to the best of my ability and understanding with the light before me. (Applause.) I beg of you, then, that should it be my privilege and yours to meet at Atlanta next year, I trust I shall have your entire support. You may rely upon me doing my duty. I want you to come to me and give me the benefit of your advice. While in this exalted position, I am, so to speak, a little deity, but I want to tell you that I am but a man, subject to all the infirmities and errors of judgment that characterize other men; yet I feel that I can receive great assistance at your hands by timely advice, and this I now solicit. With these brief remarks I again thank you for the distinguished honor that you have conferred upon my State through this humble individual." (Applause.)

The President then appointed the following delegates to societies abroad: W. H. Daly, J. A. Ouchterlony, I. N. Love, C. G. Chaddock, L. H. Montgomery, A. E. Rockey, I. N. Quimby, and H. H. Bridle.

DR. GEORGE W. WEBSTER, of Chicago, offered the following, which was unanimously adopted:

*Resolved*, That a vote of thanks be tendered to the city officers, the Reception Committee, the Committee of Arrangements, the local profession and citizens, and the public press for the hearty welcome, the magnificent entertainment, the unlimited, spontaneous courtesy and hospitality, the accurate reports of proceedings, during our pleasant sojourn in the Monumental City; also a vote of thanks to the President.

DR. GEORGE H. ROBE, of Maryland, submits the following amendments to the Constitution:

1. After Par. 8, of Article II, insert the following:

"Active members shall consist of such permanent members as have attended three meetings of the Association and shall have all the privileges of delegates, so long as they conform to the regulations of the Association."

2. Insert in line 6, of Par. 6, Article IV, relating to duties of officers:

"He shall, in conjunction with the Local Committee of Arrangements, make complete arrangements for the verification of the credentials of delegates, and for the registration of members. He shall also prepare annually an accurate list of members of the Association."

3. That ordinance No. 18 be amended by substituting "The Permanent Secretary" for "Committee of Arrangements."

THE SECRETARY then read the

#### REPORT OF THE GENERAL BUSINESS COMMITTEE.

Upon the request of the Section on Materia Medica and

Pharmacy, the General Business Committee, recommends to the Association that the work in therapeutics be added to that of the Section, and that the name of the Section be changed to that of the Section on Materia Medica, Pharmacy and Therapeutics.

Upon the unanimous request of the Section on Dermatology and Syphilography, the General Business Committee requests that the name of the Section be changed to that of the Section on Cutaneous Medicine and Surgery, as it is believed that thereby there will be greater interest excited in the work of the Section on the part of the general practitioner.

The General Business Committee indorses the following recommendations from the Section on Materia Medica and Pharmacy:

*Resolved*, That in view of the adoption of the metric system in the U. S. Pharmacopoeia, this Section recommends the more thorough instruction of the students at the medical schools in the use of metric weights and measures, and further recommends that physicians, when writing metric prescriptions, always make use of the signs Grm. and Cc. to distinguish between quantities by weight and volume.

The General Business Committee gives notice of an Amendment to Article —, Section VII, relating to the establishment of the Committee, to the effect that, "officers of Sections shall fill vacancies temporarily in their Executive Committees, to serve on the General Business Committee during the current meeting of the Association."

L. DUNCAN BULKLEY, M.D.

Secretary General Business Committee.

*To the American Medical Association*:—Recognizing their high responsibilities in regard to the sectional and scientific work of the Association, and the need of fostering it in every way possible, your General Business Committee gave long and very careful consideration to the resolution which was referred to it, making the regular time for the reception of the report of the Nominating Committee to be Thursday instead of Friday, as has been the custom. In view of the amendment which has been proposed, devoting the entire day of Thursday to sectional work, omitting the General Session entirely on that day, and for many other reasons, your Committee unanimously resolved that it was not expedient to change the customary date of receiving the report of the Nominating Committee.

On motion of Dr. Cochran, the report was adopted with the exception of those portions which introduce changes in the By-Laws, which must lie over for one year.

The following resolutions from the State delegation of New Jersey were read and adopted:

*Resolved*, That the American Medical Association renews and hereby confirms its long-standing allegiance to and defense of the letter and the spirit of the unamended Code of Ethics and etiquette of the American Medical Association; and further

*Resolved*, That any revision of that Code on the lines hitherto adopted or proposed, should be rejected by every regular practitioner of medicine as being inimical to the honor of the medical profession and subversive of the best interests of the people of the United States.

ALEX. MCALLISTER, Chairman State Delegates of New Jersey.

#### REPORT OF LIBRARIAN.

The following report of the Librarian was offered and accepted without being read in full:

*To the President and Members of the American Medical Association*:—Your Librarian begs leave to submit the following:

During the past year all the books, etc., constituting the library of the American Medical Association have been transferred from Washington, D. C., to the Newberry Library at Chicago, in accordance with the terms agreed upon at a former meeting. A certified copy of this agreement is appended hereto.

The report of the Librarian of the Newberry Library shows that our library consisted of 3,781 volumes, 3,708 pamphlets. In accordance with the terms of our contract, these will be classified, bound, shelved, and for the first time in the history of our Association, be accessible to the profession.

Now that a permanent home and proper care is assured for our books and journals, there is an abiding reason for continued and generous contributions from the members of the Association. Respectfully,

GEORGE W. WEBSTER, Librarian.

*To the American Medical Association*:—The main part of the Library of the American Medical Association, now in the Newberry Library, filled seventy-four cases. It was supplemented by the exchanges of the JOURNAL office for the period, 1890-94, and by the exchanges sent directly to Dr. Webster. A rough count of the volumes and pamphlets gives the following figures: volumes, 3,781; pamphlets, 3,708.

Perhaps 95 per cent. of the collection consists of periodicals, transactions and reports; of which the most of those

published before 1885 are bound. The arrangement of the unbound volumes is not completed; but the work has gone far enough to show that few, if any, of the sets are perfect.

The percentage of single volumes is comparatively small, most of them being old books. Among these are a number of works on cholera. Some of the volumes have been ruined by damp, while others have been mutilated by roughly tearing off the covers; on the whole, however, the books and pamphlets are in a good state of preservation.

Recent exchanges are represented to the number of 250. This includes nearly all the United States medical publications; some from Europe, and many from the Central and South American States. The medical and learned societies of Europe are well represented as are our own State societies. The transactions of these societies are particularly valuable for library purposes.

There is also a good showing of United States medical periodicals, printed early in the century and coming down as late as 1850.

The pamphlets consist largely of reprints from United States medical journals and of the publications of German universities, notably those of the University of Kiel. There are also some early files of insane hospital reports.

According to the terms of the arrangement entered into between the Association and the Trustees of the Newberry Library, the volumes and pamphlets will receive a mark showing the source of acquisition. It is hoped that the members of the Association will continue to manifest their interest in the Library by forwarding to it copies of their works.

J. V. CHENEY, Librarian.

#### THE NEWBERRY LIBRARY AGREEMENT.

It is hereby mutually agreed by the Trustees of the American Medical Association and the Trustees of the Newberry Library that the American Medical Association shall permanently deposit in the Newberry Library its entire collection of books and pamphlets now in the Smithsonian Institution at Washington, or elsewhere, and in consideration thereof the following arrangements are made and agreed upon, namely:

1. That the said books and pamphlets shall be treated by the Newberry Library in all respects as its own, and as it treats its own books, except that in labeling, stamping, or otherwise marking them, they shall, when received, be so marked as to show that they belong to the collection received from the American Medical Association; and the said Association shall never thereafter have the right to remove said collection of books or any part thereof from the custody and control of the Newberry Library.

2. That duplicates or other books may be exchanged or sold at the discretion of the Librarian or Trustees, but that such books received in exchange or purchased with the proceeds of sale shall be marked or stamped as above provided for.

3. That the American Medical Association shall hereafter continue to deposit in the Newberry Library all the books, journals, etc., donated or contributed to it from any and all sources; except those given to reviewers for writing the reviews, and such journals as are needed to keep complete files in the office of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. All such books, etc., shall be treated in all respects as hereinbefore provided concerning the collection at present existing.

4. That the Newberry Library shall defray the expense of transporting the aforesaid collection to the Newberry Library.

Dec. 5, 1894.

THE NEWBERRY LIBRARY,

By EDWARD S. ISHAM, First Vice-President.

Attest: R. B. McCONNEL, Secretary.

GEO. W. WEBSTER, Librarian A. M. A., June, 1894,  
A. GARCELON, President Board of Trustees.

Attest: JOHN B. HAMILTON, Secretary.

The following resolutions from the American Pharmaceutical Association were offered and adopted.

In response to the resolution sent from the American Medical Association, the American Pharmaceutical Association offer the following:

*Resolved*, That the American Pharmaceutical Association condemns the prescribing and dispensing of proprietary medicines; and while the necessity of protecting capital invested in the manufacture and marketing of galenical preparations is recognized, we protest against any system of protection which permits one manufacturer to retain the exclusive control of a pharmaceutical product indefinitely, and regard the law which permits it as opposed to true progress in pharmacy and medicine.

*Resolved*, That the working formula of every pharmaceutical preparation should be published, and a technically correct scientific name given it, so that it may appear in professional literature, find a place in the

Pharmacopœia or National Formulary, and be free to all pharmacists to manufacture and sell.

*Resolved*, That physicians be particularly requested to consult the United States Pharmacopœia and National Formulary in prescribing galenical preparations, and that we request both of these works be made text-books in the medical colleges.

J. M. GOOD,

WILLIAM C. ALPERS.

THE SECRETARY read the following:

#### DECISION OF JUDICIAL COUNCIL.

May 9, 1895.

The papers referred to the Judicial Council concerning the Texas State Medical Association consist of a printed pamphlet severely reviewing the past action of the Texas Association, and a letter from the author, apparently, asking the Committee on Registration to suspend the registration of delegates from the Texas Association until a proper protest can be presented. But as no such protest accompanies the papers received by this council, there is nothing in form ready for the action of the Judicial Council of the American Medical Association.

JOHN B. ROBERTS, Secretary.

By order of Council.

DR. GINON offered the following, which was adopted:

*Resolved*, That the cost of the necessary printing and distribution of circulars for the Rush Monument Committee shall be defrayed by the Association on vouchers certified by the Chairman and Secretary of that Committee.

DR. HERR, of Lancaster, Pa., offered the following, which was adopted:

WHEREAS, Many of our ablest and most honorable members have been Acting Assistant Surgeons in the service of the United States during the War of the Rebellion, occupying responsible positions and subject to the same rules of discipline as commissioned officers, and enlisted men; it is the sense of this society that the Congress of the United States should, by enactment, place them where they honorably served, upon the same plane of distinction as commissioned officers of the same grade; therefore be it

*Resolved*, That this body recommend Congress to enact such legislation as will place all those who served as Acting Assistant Surgeons during the years from 1861 to 1865, and who were honorably dismissed, the same distinction as commissioned officers in the same grade of service.

The Association, on motion, adjourned to meet in Atlanta, Ga., the first Tuesday in May, 1896.

## SELECTIONS.

**Tuberculous Adenoid Vegetations of Naso-Pharynx.**—M. Lermoyez (*Ann. des malad. de l'oreille, etc.*, 1894, No. 10) alludes to some experiences with adenoid growths in the naso-pharynx, which, on examination proved to be not lymphatic, but tuberculous in structure. In such cases the removal of the growths gave only a temporary relief; a return soon followed. In one case a rapid development of tubercle of the lungs followed the operation. The writer proposes in all cases where there may be a suspicion as to the tuberculous nature of the adenoid growths to forestall the operation by a histological examination of a test portion and to complete the operation finally by galvano-cautery in order to hinder the entrance of germs into the opened blood vessels. The subject is quite important, but the writer's material was so scanty that further investigations in this direction are earnestly desired.

**A Case of Tubercular Meningitis, with Recovery.**—(Freyhan in *Deutsche med. Wochenschrift*.) Existing opinions in general are against the possibility of recovery from tubercular meningitis since the brain is only in rare cases the sole point of infection, but a general miliary tuberculosis, as a rule, exists. So much the more interesting is the observation at the city hospital at Friedrichshain in Berlin of an instance of recovery, in which the tuberculous nature of the process was most infallibly shown. The diagnosis was proved by puncture of the spinal canal at the level of the second lumbar vertebra and by drawing 60 c.c. slightly turbid, light colored serum, in the sediment of which was found a scanty number of pus corpuscles and undoubted, deep red, tubercle bacilli, arranged like strings of pearls, whose presence was further assured by numerous control preparations. After the puncture the patient recovered so quickly and uninter-

ruptedly that after three weeks without fever he was able to leave his bed. This case is also instructive with regard to the differential diagnosis between tubercular and cerebro-spinal meningitis. The recovery of a case in which opinion has wavered between these two affections, usually tends to strengthen the diagnosis of cerebro-spinal meningitis. The result of a puncture in connection with the microscopic and bacteriologic investigations is destined to clear the point. Entirely aside from the therapeutic value of this method, it is certain we possess in it a diagnostic resource of the first rank in the differential diagnosis between tubercular and cerebro-spinal meningitis.—*Centralblatt für innere Medicin.*

**Omphalectomy in Radical Operations for Umbilical Hernia.**—Dr. L. Pernice, surgeon to the Deaconess' Hospital at Frankfort, relates in detail an operation on a very corpulent woman for a long-standing, irreducible, umbilical hernia as large as a child's head. The operation was undertaken on account of constipation, pain, and persistent vomiting. The incision was about 25 cm. long, and passed in a semicircle to the left of the umbilicus. A short incision passed to the right of the umbilicus and so completed an oval which was excised with the sac and the margins of the rectus muscle. The inflated intestines were replaced with great difficulty. Then, following Bruns' recommendation of the plan of Condamin, he attempted the suturing in three layers, found this impossible from the tension, and even with the single layer was forced to resort to silver wire, and to use many sutures. The patient did well; stool on the fifth day after calomel; no rise of temperature, except on the eleventh day (38.4 degrees C.), when four days had elapsed without stool. All sutures removed on the sixteenth day. On the eighteenth day sudden dyspnea and cyanosis and she died within fifteen minutes from pulmonary embolism.

"I would especially emphasize that I do not ascribe this death to the method of operating, but to an accident. Although a post-mortem was refused, the diagnosis of embolism seems sufficiently assured. The operation in itself is simple; excision of the umbilicus is easy; replacing of the intestines would not in most cases be hard; but the greatest difficulty in the operation lies in closing the wound. The Condamin method of suturing can not be recommended. On the strength of this one case, I feel compelled to regard the usefulness of this new operation as limited. While in Bruns' case the hernial opening admitted the tips of two fingers, in mine five or six could easily enter, hence it was at least three times as broad. After such an excision the edges of the wound were separated too far to be easily brought together. And when, moreover, the hernial sac has long contained many coils of intestines, and the abdominal cavity has become diminished in size, it will be seen that the difficulty of closing the wound is much increased after the hernial contents have been replaced."—*Centralblatt für Chirurgie.*

**Snegirjoff Steam.**—A new Hemostatic. Preliminary Report. (Clinical Lectures of Professor Zacharyn and the work in the clinic of the Faculty of Therapeutics of the Imperial Univ. of Moscow.) This work of the distinguished Moscow gynecologist deserves special attention. In 1893 he extirpated an echinococcus cyst of the liver which protruded from the left lobe with a base of four fingers breadth. Since the base of the tumor was very thick and he yet wished to remove the entire sac, he tried to divide the pedicle with the actual cautery, but failed completely in stopping the hemorrhage, until at last he filled the wound with gauze as a tampon. The woman recovered. He was convinced, as other surgeons have been, of the inadequacy of our means of hemostasis from the liver. Sutures cut through, mattress-sutures can not always be used, cautery is often insufficient,

so that marpy scraps (Scotch gauze) become necessary. In this way there occurred to him another long known hemostatic.

Seven or eight years before, he had used steam as a cautery and hemostatic in gynecologic therapeutics. After a dilatation of the cervix and curetting, for instance, he passed into the uterus a catheter, perforated at the end, like a sieve, within which was a thin metal tube, connected with a steam boiler supply. The application of steam at about 100 degrees C., for a half to one minute was sufficient for cauterization and hemostasis and this was recognized by the discharge from the catheter of a dark-colored fluid, resembling strong bouillon in appearance. This operation is painless and the patient does not recognize the moment of application of the steam. What happens within the uterus? In the extirpated uterus, at an experimental trial, the mucous membrane immediately afterward appeared scalded, covered with a thin white pellicle. In cases where there was putrefaction, at once all odor disappeared; where the mucous membrane was painful, the pain was removed; if one adds the antiseptics accomplished by the steam, then its full significance is seen; cauterization, hemostasis, anesthetization and antiseptics. All this had long been known to him, but now he turned his special attention to the hemostatic action and conducted a series of experiments on animals with specially constructed instruments: 1, without any loss of blood portions of liver were removed, the animals surviving; similarly, parts of the spleen, the lung, the kidney, the brain; 2, hemorrhage from the cancellous tissue of bone was stopped. The marrow was scalded and reformation of true bone (?) resulted; 3, in a dog it was possible to remove a horn of the uterus without hemorrhage; 4, the femoral artery was severed diagonally or transversely without hemorrhage; 5, hemorrhage from wounds of muscles or skin ceased at once; 6, furthermore, primary union followed. The final experience was not only with animals, but also in operations on man, and even in laparotomies.

In 1893, he used steam in the Alexina Hospital in the following operations: 1, in five cases of resection of the knee-joint, without hemostatic forceps, without a single ligature; 2, in an amputation of the breast for cancer, also without a ligature; 3, in removal of cancerous, lipomatous or cavernous neoplasms of the skin; 4, in amputation of the cervix uteri; 5, in stopping hemorrhage from the pedicle after removal of fibroids; 6, in abscesses for disinfection and stimulation to cicatrization; 7, for hemorrhages from sinuses and fistula (especially in tuberculosis).

On the strength of this, Snegirjoff pronounces steam a powerful hemostatic and antiseptic. Sound as well as diseased tissues, and the organism *in toto* bore the action of steam vaporization well. Primary union was not prevented, the wounds of parenchymatous organs appeared smooth, even shining, at the site of removal of tumor. By way of illustration, Snegirjoff dictated a description of the examination of a dog subsequent to operation: in the region of the left kidney a piece of the left horn of the uterus, 2 cm. long, in which, as in a cyst, was a collection of fluid, was attached to the broad ligament. Over the steamed surface was a smooth cicatrix, pigmented in the center. The lumen of the left horn of the uterus, at the point of excision was firmly closed, in consequence of which the cyst-like collection of fluid resulted. The margin of the broad ligament, along the incision was smooth, even without noticeable cicatricial contraction. The peritoneum was smooth, moist, shining. No pathologic changes in the para-uterine or other pelvic cellular tissue. There were large blood vessels in the broad ligament of the remaining portion of the left horn of the uterus.

In view of this, the surgeon can without fear remove portions of parenchymatous organs. The far-reaching significance of the results thus made public is evident. If the statements are fully confirmed, the work of the active and vigorous Moscow college will bring about a revolution in the whole technique of operations. Steaming would have the greatest value in hemorrhage in laparotomy for extra-uterine pregnancy, in atony of the uterus, after injuries of the soft parts in delivery, after symphysiotomy, in rupture of the uterus, all the operations for cancer, etc.—*Centralblatt für Gynakologie.*

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MAY 18, 1895.

THE BALTIMORE MEETING.

The forty-sixth annual meeting was characterized throughout by great harmony. The Section work has seldom been better managed, and the attendance was larger than the average. The ASSOCIATION, by an overwhelming vote, indefinitely postponed all proposed amendments to the Constitution and there will therefore be none of consequence to be voted upon at the Atlanta meeting.

The vote by which the Secretary and the Treasurer are required to be in attendance one day before the opening session, for the purpose of better organization of the registration, will save much annoyance to the members, and relieve the local committee of much of its burden.

The action of the Board of Trustees in regard to the advertising was the subject of much favorable remark. This action, which appears in detail in the report, was agreed upon at the Chicago meeting of the Board, but as two members were unable to be present at the Chicago meeting, the Board were not ready to report earlier than on Thursday. An attempt was made on Monday to compel them to report at once, and to have a special committee appointed to inquire into its nature, but the ASSOCIATION declined by a majority vote to appoint a committee, the effect of which would have been to create distrust. When the report was made, it was so clearly in the line desired by the mover of the resolution, DR. S. SOLIS-COHEN, of Philadelphia, that that gentleman himself, amidst thundering plaudits of the meeting, moved its adoption in an eloquent speech. This action of DR. COHEN at once proved

the sincerity of his course, and the practical unanimity of all parties composing the ASSOCIATION. Now that the advertising question has been eliminated from further consideration, we sincerely trust that all may work the harder to sustain, support and improve the JOURNAL. It is due the Trustees to state publicly that the change finally adopted has been gradually going on, for the last year, and as fast as contracts have expired the formula has been required from advertisers of proprietary medicines. It will take some time to bring the remainder into line. The members will please to understand that those carried beyond this issue are only awaiting the expiration of the existing contract.

PRESIDENT MACLEAN still further added to his well-won laurels by the dignity and wisdom with which he performed his difficult duties. In the election of DR. R. BEVERLY COLE, of San Francisco, a tribute was paid to long and faithful service in the ASSOCIATION, recognition of a medical teacher of National reputation, a sanitarian of eminence, and a compliment to the profession of the Pacific coast.

The minutes of the general sessions, which we present in full in this issue, will, we feel sure, be of unusual interest, not only to those members who were present at the meeting, but as well to the larger body of our colleagues who were compelled to remain at home.

The social features of the meeting were quite sufficient to occupy all the time at the disposal of the members and the ladies by whom many were accompanied. Baltimore looked its best. The boulevards are fresher at this season than at any other; the grass and the leaves a more vivid green; the flowering shrubs, the wisteria clusters with their delicate heliotrope coloring, everywhere met the eye, and the fragrance of lilacs pervaded the air. Nowhere in America, except in Washington, does one see cleaner streets than in Baltimore, and if certain sanitarians do occasionally take a fling at the policy which prevents the construction of sewers, it must be admitted that the month of May in Baltimore is a very charming month indeed.

The teachers at the Johns Hopkins Hospital had every opportunity to show to good advantage the high class work they are doing, and that they made full use of the opportunity thus offered was as pleasing to the ASSOCIATION as it was creditable to themselves.

In conclusion, it may be said that those elements which go to make up the *tout ensemble* of a successful meeting of our great ASSOCIATION, viz., harmony, science and social pleasure, the forty-sixth annual meeting possessed in an eminent degree.

Blank Applications for membership in the ASSOCIATION at the JOURNAL office.

## THE WORK OF THE PRINCIPAL SECTIONS.

This number of the JOURNAL is preëminently the ASSOCIATION number, for we have a verbatim report of the discussions and debates in the general sessions, and as well the resolutions passed therein. The bare report of the final action of the body, without a statement of the debate which gave direction, is sometimes unintelligible to those who were not present.

The work of the Sections was in general characterized by thoroughness and enthusiasm. We append a brief review:

## PRACTICE OF MEDICINE.

An unusually large number of papers were read in the Section on Practice of Medicine. The topics were well selected and the authors gave more than usual care to their preparation. We have a pleasure in store for our readers who were not present at the meeting, in the perusal of the papers of this Section.

## SURGERY AND ANATOMY.

The work of the Surgical Section comprised the presentation of forty papers. Of these papers all but ten were read. The latter were read by title, and will be published in the proceedings of the Section. Whereas the range of subjects covered the entire field of practical surgery, a number of special subjects were extensively considered. Among those of special interest were, "The Surgery of the Kidney and Ureters," and "Modern Methods of Cystoscopic Examinations of the deep Urethra and Bladder." Abdominal surgery was further considered in papers and discussions upon, "Appendicitis," "Intestinal Obstruction," and "Surgery of the Gall-Bladder." To accomplish the reading of all the papers, the Chairman of the Section felt it incumbent without favoritism to enforce the twenty minute rule as to the reading of papers, and the five minute rule for the discussions. The good judgment of the Section at large was amply illustrated in discussing particularly those questions which were of paramount interest, and passing, without comment, papers of less general interest and importance. Altogether, the work of the Section was fully equal to the best efforts in the same direction of previous years. If any exception could be taken to this work, with the view of improving Section work for the future, it would be in the number of the papers read. As the Section work is now constituted, the Chairman of the Section is not empowered to refuse volunteer papers. The time must come when all papers will be presented to a proper committee and deemed worthy of a place upon the program before they can be submitted to the Section by their authors. J. R.

## OBSTETRICS AND DISEASES OF WOMEN.

The work of the Gynecologic Section was satisfactory to a high degree. As will be seen from the reports, the papers presented were of an unusually

high order, both as to subject matter and manner of treatment. The discussions were spirited and were led by men qualified to speak with weight upon the points at issue.

The attendance at each session was large and interested, the only drawback to the enjoyment of the meetings being the difficulty of hearing speakers in so large an auditorium, the acoustic properties of which were bad. Withal, the Chairman of the Section, DR. FRANKLIN H. MARTIN, is to be congratulated upon the unqualified success of the department over which he presided. The Chairman-elect of this Section is DR. JOSEPH TABOR JOHNSON, of Washington, D. C.

H. P. N.

## OPHTHALMOLOGY.

The sessions of the Section on Ophthalmology brought together probably the largest number of working ophthalmologists that have ever assembled in America. The restriction of papers to ten minutes, and of remarks in discussion to five minutes for each speaker, was noted to be more effectual in keeping out matter lacking general interest, and in holding the speakers to the point under discussion, than any other means that have been tried.

In arranging the work of this Section all the papers on the same or related topics had been carefully grouped together; and time had been provided for their discussion, and speakers invited to open the discussions. The result was not only that large numbers came to the meeting to attend this Section, but that they closely followed its sittings up to the last day of the meeting.

The series of papers on operations on the ocular muscles; and other methods of treating muscular anomalies; on plastic operations about the eye; and on astigmatism, with the discussions they elicited, will long be remembered by those present. What was felt to be the most serious defect in the program was the arrangement of receptions on the evening of the Section dinner. This annual dinner has become a highly appreciated occasion of reunion; and the feeling in this Section is very strong that in arranging for future meetings one evening, preferably the second, should be devoted entirely to Section dinners.

E. J.

## NEUROLOGY AND MEDICAL JURISPRUDENCE.

The Section on Neurology and Medical Jurisprudence at the Baltimore meeting, had the largest attendance and the greatest number of scientific papers of any previous meeting of the Section. The average attendance exceeded that of any other Section of the ASSOCIATION.

The scientific work was arranged principally in three symposia, to-wit: hypnotism, electricity and epilepsy, and about a dozen papers were read on miscellaneous topics on neurology. The discussions were unusually good, and participated in by some of the ablest neurologists in America.

D. R. B.

## STATE MEDICINE.

The Section on State Medicine had an unusually large attendance. There were thirty-eight papers on the program, twenty-two of which were read. The symposium on alcohol by members of the American Medical Temperance Association was one of the distinguishing features, and the character of the papers was of high scientific value. The appointment of a special commission to investigate the alcohol question will doubtless be hastened by these preliminary discussions in the Section. The Section, as will be seen elsewhere, loyally adhered to the ASSOCIATION movement for the establishment of a Department of Public Health.

## DISEASES OF CHILDREN.

This Section, which has languished for the last two years, sprung into new life under the active efforts of its Chairman, and the meeting this year was the largest ever held. In scientific value the papers were fully equal to those of the Detroit meeting, which up to this time has been supposed to be its best meeting.

## LARYNGOLOGY AND OTOTOLOGY.

The work of this Section exhibits the same general advance in interest that was manifest last year. The attendance was more than three times that at San Francisco, and several of the leaders who of late have been conspicuous by their absence from the ASSOCIATION meetings, were present and warmly welcomed.

## CONCENTRATED FOOD AND ARMY RATIONS.

A ration, in the phraseology of Army Regulations, is the "established daily allowance of food for one man." The regular ration of the United States Army is accepted by all as liberal and satisfactory; but as it may not always be possible to issue it during active service, the question of an emergency ration has been under discussion, for some time back, in Army circles. Recently a practical turn has been given to the subject which promises to yield results that will be of value, not only to the soldier, but to the country at large. GENERAL MORGAN, Commissary General of Subsistence, has invited the attention of the Secretary of War to the want in our service of a special ration to be carried by each soldier and used only when the regular issue can not be made. Such a ration should combine the properties of wholesomeness, palatability, proper nutritive value and portability, and should in addition possess good keeping qualities. MAJOR WOODRUFF, of the Commissary General's office, has elaborated a ration of biscuit and soup tablets, the latter containing the fiber of the meat, which is regarded as furnishing the needful nutritive principles in a minimum of bulk and weight; but before recommending the adoption of this, GENERAL MORGAN desired to have the coöpe-

ration of line and medical officers in considering the question and determining the selection. He therefore suggested that in each of the military departments a board, of one subsistence, one medical and three line officers, be convened to consider and recommend a proper ration for troops operating in emergencies, and that each of these boards give special consideration to the following points: "1, the component parts of the ration selected with regard to wholesomeness, nutritive value and portability; 2, acceptability to taste; 3, keeping qualities; 4, weight, and the kind, size and form of package for convenience of use and of carriage on the person; 5, directions for use; 6, number of rations to be carried by the soldier, and 7, whether these are to be carried at all times as a part of the equipment or to be issued only as required by the probable emergency. If after the reports have been received by the commanding general it should be found that there are material differences of opinion it is suggested that a board of officers be convened at Washington to reconcile these differences if practicable. I also recommend that a sum not exceeding \$100 [and this is the practical part of the recommendation] from subsistence funds be assigned to each board to meet the expenses of materials and preparations thereof in the experiments necessary to be made by it." The Secretary of War has approved the General's recommendation and these boards will speedily be organized.

The emergency ration of foreign armies consists generally of biscuit and meats, pemmican, sausage, stews, soups, etc., put up in hermetically sealed tins and prepared usually at private factories. Of these the pemmican is regarded as the highest concentration, four ounces being considered equivalent to one pound of meat. The meat biscuits, 25 per cent meat and 75 per cent flour, formerly used in the British service were found to keep very well; but as the baking at about 500 degrees Fah. was believed to injure the nutritive value of the meat, their use was discontinued. For some years preserved meats from Australia, Argentina and the United States were used by the British government. Chicago canned beef was regarded by the medical officers of the Netley Medical School as having more than twice the nutritive value of an equal weight of good roast beef. This canned beef with its high nutritive value costs in the United States less per pound than fresh meat, with its large percentage of refuse and its liability to become tainted. Students of domestic economy should make note of this important fact. Germany established canneries as long ago as 1870, and is now able to turn out daily nearly half a million of meat rations. Up to this time France has depended on the United States and Australia for a canned meat ration; but a recent Army Commission has reported against any further con-

tracts for these meats, on the ground that the foreign manufacturers before canning the meat, extract from it a concentrated bouillon from which they make Liebig's extract and solidified soups. They are thus able to underbid French manufacturers who put into their cans every particle of the nutritive elements of the meat. The Commission therefore urges an appropriation for the establishment of governmental canneries.

Beef extracts are not used as emergency rations by any of the governments. The meat fiber is present in all; but in most of the samples, particularly in the patent or cooked rations of various makers, on trial by military authorities, there is an unnecessary amount of water. In some this non-essential water constitutes more than half of the bulk. In the form of biscuit, farinaceous foods appear to approach as near as possible to the condition of water free food. It is therefore mainly to the elaboration of the meat ration that the attention of the boards to be convened at the request of GENERAL MORGAN, will no doubt be directed,

#### PERILS OF THE LABORATORY.

It has been so, since the world began, that the pathologist takes his life in his hand. There are, we believe, far fewer dissecting-room wounds now than before the Listerian era, but the grounds of peril have not been removed; they have been shifted to the laboratory. When one considers the vast army of laboratory workers, however, and the minute and almost unintermittent toil given by many of such workers, is it not strange that more frequent misadventures by infection have not been reported? The rules of all well-constituted laboratories are rigid, and recognized to be in the line of the self-preservation of the workers. These are all very well and yet they doubtless do not, and can not, cover all the points of peril coming from atmospheric infection; take, for example, the ærial carriage of the tuberculous bacillus, in the form of floating floor-dust, after the break-age or upsetting of a tuberculosis culture.

The death of DR. JOHN M. BYRON, of New York Quarantine Station, has recently been reported, and is believed to be an instance of the fatal results of laboratory infection by tuberculosis. His death at the early age of 35 years means the untimely removal from the ranks of the profession of an exemplary scientist, a man who has already achieved a more than local reputation.

DR. JOHN MANUEL BYRON was a Peruvian by birth and a graduate from the University of Lima. After taking his degree he went to Europe and spent several years in study, making a specialty of the diseases originating in bacteria. He visited Paris and Berlin, attended medical lectures, and pursued original investigations in the hospitals. He then went

to Naples, and settled down there to practice. He was proficient in five languages—inclusive of his native tongue, the Spanish. About seven years ago, he took up his residence in New York. He never practiced very much, preferring the life of the laboratory. He was appointed chief of the bacteriologic department of the Loomis Laboratory, and lecturer in that branch in the University Medical College. In addition to this work he was connected with the New York Dispensary. He did not court outside practice, but used all his leisure in the study of his specialty in the Loomis Laboratory, where he gave special attention to the bacterial study of malarial fevers and leprosy. During the cholera scares of 1892 and 1893, he was made the pathologist to the Swinburne Island Hospital, and was isolated there until the cases were all closed by recovery or death. Health Officer of the Port, DR. DORY, had only recently appointed him to a similar but larger line of work, as the bacteriologist of the quarantine establishment of New York Harbor. Concerning his own experience in regard to the onset of tuberculosis, he is reported to have expressed himself as follows:

"I have been making cultures of disease germs for twelve years, and I suppose familiarity with them made me careless, just as a surgeon frequently cuts himself with his knife. You know it was our custom to get the sputum of patients in the hospitals suffering from consumption, and to find this bacteria. These are generally confined in bottles or tubes when not in use, but when we want to put them under the microscope they are spread out on glass.

"One is practically safe as long as they are wet, but when they become dry they fill the air as so much dust, and you can not help but inhale them. It is in this way, you know, that consumption spreads.

"I was somewhat run down last February—in fact, I had never become very strong after my exposure during the cholera scare. I was doing some experimenting with tuberculosis bacteria at the time, and I suppose that some of them had been allowed to dry—how, I don't know—but it may be that some were brushed to the floor during our researches, or that the bottles were not thoroughly sterilized, or in any of the thousand and one ways in which carelessness may exhibit itself."

#### ON THE RIGHT TRACK.

The JOURNAL hastens to seize the present promise—before it fades away fruitless—that the opponents of oleomargarine are about to fight that product on legitimate grounds. Bills are pending in sundry State Legislatures to forbid the addition of coloring matter to oleomargarine or any of its variants whereby it may be butter in appearance—"the same with intent to deceive."

This is laudable and proper. Every honest citizen who hates sham and fraud will join the JOURNAL in applauding such a measure. Let us have our oleomargarine in its pristine purity, like the pearl from which its name is borrowed. Let us have no sailing

## ADDRESSES.

### ADDRESS ON SURGERY.

Delivered at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY C. A. WHEATON, M.D.

ST. PAUL, MINN.

A retrospective examination of surgical literature since the advent of anesthesia does much to make the thinking student wonder whether the longevity of the human family has been conserved, or its physical welfare materially enhanced by modern surgery. That the operating room has been robbed of its terrors by ether and chloroform is conceded. That the clinical chart no longer presents the erratic markings of the clinical thermometer as influenced by a body aflame with the products of infection, ignorantly permitted to obtain a foothold in the human economy, is also admitted—but has not our feeling of safety, engendered by our acknowledged perfection in surgical detail, opened a wide field of surgical speculation and experiment which serves rather to enrich the surgeon than to minimize disease and prolong life. In my humble opinion the segregation of our professional work is in a large degree responsible for much of the opprobrium which attaches to the over-zealous pursuit of a given theory or special method of doing an operation whose only excuse for being done is the desire to elaborate a hobby. The practice of the various branches of our profession to-day is practically relegated to the different specialties. I would not underestimate or undervalue the great achievements of such men as Senn, Kelly, Price, Polk, and many others in this country, and with such guiding hands as Keith, Tait, Creig, Smith, Treves, Fenwick, Batlin, Heath, and a host of others in the British Islands. With continental Europe teeming with the literature of such medical Nestors as Billroth, Charcow, Virchow, Pasteur, Koch, and the prominent members of the present French school, is it any wonder that we occasionally pause in amazement at the accomplishments of the members of "our cloth" in all the civilized countries of the world, and wonder whether it is not all a chronicle that might have been contemporaneous with the Arabian Nights, or heralded by a Sancho Panza. That this whole magnificent fabric should have been evolved from an intimate acquaintance with the primary cell, whose intrinsic importance is just beginning to unfold itself to the scientific thinkers and workers in the various branches of our art, is harder to conceive and more difficult to believe than the revelations of the Book of Genesis or its associates in the whole autonomy of man.

It is said that "the sovereignty of reason is the sphere of morals; or man's power as possessed of reason to give law to himself." In following this line

of thought he who assumes to dictate the destinies of so many of his fellow creatures should be well caparisoned for the fray and should be symmetrical in his professional growth in order that he may discharge with dignity, proficiency and honor the obligations that fall to his lot as a surgeon. He can not be such an one, unless his professional superstructure is built upon a fundamental basis, such as is born of a thorough knowledge of all the collateral arts and sciences which bear intimate relation to his life work. I believe that the specialist of the future, no matter what avenue he elect to follow, should be a regular graduate in all the branches of medicine, and should serve a sufficiently long period in the field of general medicine to raise him above the level of mediocrity before he assumes to pose on the witness stand as an oracle in nervous disease, or at the bedside to advise for or against an abdominal section. I confess to a feeling of sentiment and regret when I think of the decline of the family physician. There was a time in the childhood of most of us when that functionary was one of the most important adjuncts of the domestic circle—his edict was law—his coming was a pleasure and his going a regret. He was consulted in matters domestic, financial, political, and if his advice was not always heeded it was usually sound and healthful. As the nineteenth century advances he is becoming year by year a greater rarity, and I regret it, for I believe it is from the ranks of such men that our specialists should be recruited. That time-honored quotation from the early Sanscrit is specially apropos in this connection: "A surgeon not a physician is as a bird with one wing." How truthful and full of meaning this old aphorism is—if his surgical growth is not symmetrical, his professional career must of necessity be full of doubt, hazard and disappointment, fraught with wretchedness to himself, danger to his patient, and unjust criticism of his art.

A review of the evolution of surgery as a science since the birth of anesthesia, is indeed a wonderful story. Operative surgery was practically shorn of its terrors and in less than a quarter of a century thereafter, through the agency of Mr. Joseph Lister and his co-workers, the possibilities of surgical convalescence were understood, and now with the revelations of the microscope in connection with bacteriology we would seem to be approaching a surgical millennium. And we might almost think we had attained it, were it not for some of the license which is a common accompaniment of great victories—I refer to what I consider some of the abuses of nature's (now known) marvelous resources. There is unfortunately no longer need for hurry in the operating room, and convalescence is assured in most cases, if we are surgically clean and our work reasonably well done. I say, unfortunately, because if the recording angel who stood at our elbow had spoken her mind, we

would have been admonished that although we had snatched our confiding victim from the "valley of the shadow," we had possibly also added weeks, months, and perhaps years of suffering and woe to one who might have been spared the long exposure of body surface or vital structures to the curious gaze of one who should have been ready to do the work, and do it promptly, when the patient was ready. There is little doubt that anesthesia is responsible for just this abuse of the operating room, and that many a tortured nervous system lives to-day to testify to the truthfulness of this statement. Let us review operative surgery in a general way and see what it has accomplished:

The cerebro-spinal axis has attained a prominent position in the forefront of latter day surgery, as a result of the painstaking untiring labor of such men as Ferrier, Horsley, Thorburn and others abroad, and a goodly array of fellow-workers on this side of the Atlantic, marshalled by such men as Keen, Roberts, Starr, and kindred students in the same field. They have done away with occultism deciphering the many maladies that owe their origin to organic changes in these most important structures. The physiology of the brain and cord is beginning to be understood, and fitting surgical remedies are at hand to successfully combat these diseases. Craniectomy has come into the surgical lists for recognition as a remedy for microcephalus, but its usefulness is doubtful and its legitimacy questioned by some of our best authorities. Laminectomy for the paralysis of Pott's disease is an operation of much less favor than formerly—it undoubtedly had a useful place in surgery when applied to paralysis as the result of trauma resulting from fracture, hemorrhage or inflammatory pressure, but otherwise the limitations of its usefulness are very circumscribed. An infinity of surgical procedure has been suggested and practiced for epilepsy but, except as applied to the disease of traumatic origin, all are of doubtful utility. One exception possibly may be taken to this statement—in occasional cases of well-marked focal or Jacksonian epilepsy—but then only after the most critical study is surgical interference to be entertained. Excision of the Gasserian ganglion for trifacial neuralgia is a comparatively recent acquisition to our list of operations. Its environments are such as to make its removal of the greatest surgical difficulty, and it will be rarely undertaken except under the most trying conditions.

Although ophthalmology has made such praiseworthy growth since Von Grafe revolutionized the extraction of cataract, it has not been without its surgical peccadillos. For example, when the popular clamor against clapping glasses on all offending eyes became of rather alarming proportions, graduated tenotomy was suggested as a remedy for all muscular insufficiencies, without other mechanical means, and it was months, yes years, before operators awakened to the fact that a buttonhole was a very good and permanent aperture in some fabrics, but muscular tissue was not among them. Otology also bears its quota of caprices, conspicuous among them being the indiscriminate angling for the ossicles, which would have reached far more extensive limits had it not been for such men as Jack and Blake whose faithful and honest reports have done much to stop this questionable method of treating dry catarrh of the middle ear. I think it is generally conceded that for sound conducting purposes, the

ankylosed ossicles as a stiff conducting rod between the drumhead and the "oval window" is far better than to have nothing but an air space interposed between the outside world and the broken foot-piece of the stirrup, bound lightly to the entrance of the labyrinth, not to mention an incus supposed to have been removed, which is still crouching in the attic, there slowly necrosing, unmindful that the war is over.

The naso-pharynx has become a labyrinth of marvels to the layman as well as the specialist—compromise of its functional integrity threatens the maintenance of all the special senses; its serious impairment is one of the gravest calamities of early childhood and may interfere with all the functions of organic life. It is the breeding ground of many of the microorganisms that threaten us upon every hand. A knowledge of its anatomy and physiology is an imperative necessity to the successful surgeon. There is little doubt that in the coming years the indiscriminate burning, lancing, probing and swabbing will become less general and the treatment of naso-pharyngeal disease will furnish fully as much of benefit to mankind, and less to criticise in its extravagances.

The surgery of the tongue, jaws and face has not materially changed in the past decade, except the improvement noticed in our plastic work about the face, aided by the Thiersch method of skin grafting. Esophageal surgery has materially increased its boundaries since gastrostomy has become an operation of comparative safety. Drainage of pulmonary cavities and operative invasion of the mediastinal spaces are, fortunately, rarely a necessity.

If his statistics are reliable, Professor Halsted has added fresh laurels to his already brilliant record, in his recently published demonstration of what can be accomplished by early and thorough removal of the breast for malignant disease; to my mind it is one of the most important bequests to modern surgery; it bids fair to revolutionize the statistics of this operation. The ghastly history of breast surgery will certainly be improved when the laity become aware of the fact that hope of cure is to be entertained if the disease has early recognition and proper operation.

In a seriatim review of human anatomy, from a surgical standpoint, one does not invade the infradiaphragmatic territory without some misgivings. It is here that we find a theater frequented by nearly all the specialists. The stomach, the gastro-intestinal circuit inclusive of the gall bladder and intestinal tube, kidneys, ureters, appendix, cæci, uterus, Fallopian tubes, ovaries, bladder and the genitalia, male and female.

Pylorotomy, and the various other plastic operations for gastric cancer, are triumphs of skill on the part of the operator and of endurance on the part of the patient, but for many obvious reasons should be rarely practiced. Gastro-intestinal anastomosis is vastly more humane and will, in most cases, contribute as much to the patient's comfortable longevity. The gall bladder has deservedly attracted much attention in the past few years; in suitable cases where anastomotic communication between this viscus and the duodenum is desirable, we have a most useful adjunct in the ingenious device of Murphy—which has proved also a great comfort in operations of emergency where lateral approximation of the intes-

tinal canal becomes a necessity. Whether it will supplant the older methods of end-to-end union of the divided gut is still a mooted question. It seems a queer dispensation of fate that so small an organ as the vermiform appendix should create so much physical woe and so much professional bickering. To the man whose faith is pinned to internal medicine (if we are to believe their reviews of its inflammation) it is not commonly the cause of much solicitude. To the surgeon who is brought in frequent contact with it at the operating table, and who has so often seen its frightful ravages, "under cloak of modest mien" it is a never-ending source of anxiety.

I hail, with gratification, the turning tide in favor of honest conservatism in the surgical management of disease within the female pelvis. It is a lamentable fact that in this, as in every other branch of surgery, in his evolution from surgical boyhood to maturity as an accomplished master of his art, the surgeon's pathway is strewn with wreckage which can only be atoned for by the greater good he is able to dispense to suffering humanity. Every State in the Union has its dozen or more laparotomists mostly gathered from the ranks of the younger men—each struggling to outdo the other in the race for supremacy, and each must of necessity leave behind him a trail of mistakes, misfortunes and accidents. A very large percentage of the material from which he gleams his experience is furnished by the female sex, and her pelvis is a most prolific field for adventure. If this battle could be fought by the giants who represent the advanced and mature thought of the day, how much better for suffering womankind might it all be. The day has gone by when every so-called cystic ovary will be removed, when ovaries are removed for symptoms rather than disease, when all tubes will be removed because they contain pus or serum. Plastic surgery will take the place of these more radical measures. Myomectomy will take the place of many hysterectomies now being done. The vaginal route will be the one of election when possible. Trachelorrhaphy will not be advised as it too often has been as a panacea for all the woes of women. Electricity will be left to the few who care to, and know, "how to use it." And in proportion as the scattered remains of her tattered anatomy and function are restored, her enlarged field of usefulness will be a benediction and a blessing to him who has wrought this change.

Bladder, ureteral and kidney surgery has received a recent impetus at the hands of Dr. Kelly, of this city; he has made it possible to secure an accurate ocular review of the mucous membrane of the "female" bladder; with his ureteral catheters, accuracy of diagnosis is attained and intelligent therapy, medical and surgical, can be applied.

The pelvic extremity of man, just now, is in greater jeopardy than any other part of his anatomy, in consequence of the recent investigations of Professor White, of Philadelphia. His remedy for senile enlargement of the prostate is probably not destined to become popular with the sex, but when his comprehensive review of the subject is digested, and we see his deductions and results corroborated by many of the most distinguished teachers in all parts of the world we are constrained to give it serious thought. It is difficult to understand why the removal of functionally inert testes should cause an atrophy of the prostate, but that such a result does follow is

established by incontrovertible proof. We have had no experience in this method of treatment of prostatic disease, but a quite large and successful experience with suprapubic prostatectomy and the known repugnance of man to part with any of his organs, *particularly these*, has prejudiced me against the operation. The ingenuity of some of the operators in ureteral surgery has demonstrated the feasibility of lateral anastomosis; it is possible and at times practicable when that tube has been accidentally injured. Some plastic operations upon the kidneys have been recorded, but of date too recent to establish their practicability. The literature of radical cure of hernia is filled with remarkable records of cure, by many different operators and by many different methods. With the exception of the series of cases reported, I think, within the past year by Professor Halsted of Johns Hopkins, none are sufficiently affirmative to make us feel that we ought to advise the operation purely as a cosmetic measure; in other words, a properly fitting truss which amply protects the hernia is a sufficient argument against radical operation. There is an element of doubt as to whether the cure will be permanent, and remote elements of danger in the operation.

There is little that is new or worthy of special consideration in the surgery of the circulatory system and little to be added to the masterly review of Senn in his experimental surgery on nerve suture. Since its infancy, orthopedic surgery has vacillated between the operative and mechanical periods. But a few years ago, arthrectomy excision or amputation was about all the attention the joint received. Then there came a sudden reaction and mechano-therapy came in vogue and is no doubt a great advancement especially in growing bones. I believe America has reason to be proud of its so-called orthopedic measures designated as American.

The conservative treatment of joint diseases is without doubt gaining in favor and demanding more attention from the surgeons of Europe. Lorenz as late as 1892 states that it is very important that the patient has the benefit of sunshine, fresh air and exercise, while the joint is protected by an apparatus which will relieve the weight of the body from the diseased joint, thus permitting freedom of exercise without pain. This has been regarded as fundamental in this country for years. The chief danger now seems to be that they carry the mechanical treatment too far, neglecting the operative.

Not a decade has passed since a prominent surgeon created considerable consternation among his fellows by making the statement that he believed that a cold abscess when it remained quiescent had best be allowed to remain so. Were the question submitted to the orthopedic surgeons of to-day I believe the majority would still be in favor of this treatment.

The aspirator is not such a universal instrument as it once was for the opening of abscesses. The results have been exceedingly unsatisfactory. Even if the flaky condition of the pus does not check its flow through the needle, the abscess cavity refills with great rapidity. From the large needle which must necessarily be used and the repeated aspiration necessary, the fibrous wall soon breaks down and we have a spontaneous opening. Thus this practice has been gradually abandoned and if surgical interference is necessary at all, a free incision with thorough cleansing is now the practice.

Of late years the club-foot shoe has largely given place to the knife and forcible replacement, open incisions, tarsectomy, free subcutaneous division with subsequent retention. The very important and useful treatment of manual and mechanical treatment is almost lost of.

Mechanical appliances, immediate rectification by osteotomy and osteoclasis for the cure of rachitic deformities seem to be receiving more attention than the early diagnosis of rachitis, and the prevention of the deformities by prophylaxis. At present the injection of iodoform seems to be much in vogue, especially in European practice. I believe that a great deal more is claimed for it than it deserves. That immobilization of a given joint is in a large degree responsible for the benefits derived from the injection treatment.

Scoliosis has attracted a great deal of attention in the past, because of the various appliances which have been exhibited, recommending forcible correction; the old treatment by gymnastics hardly seeming to deserve recognition. Torticollis has for its treatment the distinction of nerve excision.

The various appliances for the relief of congenital dislocation of the hip have been largely abandoned, and now we find the orthopedist scooping out the os innominatum for the reception of the head of the femur.

Operative interference is greatly practiced for the relief of the deformity following spinal or cerebral paralysis. A good-natured quarrel upon traction as a means of fixation in the treatment of joint diseases shows that some one is trying a hobby, if we are to judge by the Orthopedic Section of the New York Academy of Medicine. One would think from articles written and from the number of statistics regarding tuberculous joints, that little if any attention is given any other joint affection, unless it be scorbutic joints which seem at present to be rather gaining in fashion.

Orificial surgery, so-called, is one of the recent fads. It is conspicuous by its absence from the transactions of all surgical deliberative bodies.

#### CHAIRMAN'S ADDRESS.

Delivered at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY E. WELLS KELLOGG, M.D.

MILWAUKEE, WIS.

*Gentlemen of the Section on Practice of Medicine, American Medical Association:*—I cordially welcome you to the forty-sixth meeting of this Section, here, in the same city, where, nearly half a century ago, the AMERICAN MEDICAL ASSOCIATION, as a newborn infant, gave its birth-cry.

This lusty infant passed through adolescence to maturity, and now in adult life, returns to the place of its birth.

A vast change has come over the medical profession during these forty-six years. The division of labor and the specialization of the practice of medicine has taken slice after slice from the so-called "Section on Practice," and yet I believe that with all the specialization there is no section which should more interest every disciple of Esculapius.

It seems fitting that at this time we should take a backward glance over the past forty-six years to that first meeting of the newborn ASSOCIATION, and contrast the Then and Now.

Such remarkable progress has been made in certain special departments of medicine that many consider the practice of medicine as a whole, somewhat backward. But looking over the past years, we can see a progressive change of ideas and methods which, though less marked perhaps than in the special departments of gynecology and surgery is no less apparent, each year adding to the list of boons conferred upon mankind.

The changes which have taken place can not be better suggested than by quoting the following from the report of the Committee on Medical Sciences, given at the first meeting of the ASSOCIATION in Baltimore in 1849:

"The fact is established that certain etherial vapors when inhaled produce insensibility to pain, and that the most sensitive portions of the living body may be divided by the knife of the surgeon, while his patient lies in a state of unconsciousness."

This astounding fact was at that time one of the recent advances in medicine; and it proved one of the greatest blessings ever vouchsafed to man; yet the committee at that time was divided in regard to their value, one portion considering the limited amount of authenticated facts in relation to the danger of their use, a sufficient ground for opposing them. The same committee stated that another virtue still attributed to quinin was its anti-malarial effect and ventured the opinion, "That there did appear to be something like an antagonism between quinin and malaria."

The salicylates were unknown. Antipyretics were unknown and many others too numerous to mention, the discoveries in chemistry having revolutionized the practice of medicine.

As late as 1877 at the annual meeting of the ASSOCIATION the theory that many diseases were caused by minute organisms was pronounced a seductive but unwarranted assumption.

As chairman of this Section I am required to present any recent advances in the branches belonging to the Section, but in speaking of the recent advances it is not an easy task to determine which are real advances and which are only apparent advances, to be followed by retreats. We, as a people, are prone to follow fads and the medical profession is not exempt from fad followers.

The temple of medicine has been slowly building for centuries, and it continues to rise; but many stones are laid only to be removed because they do not stand the test of time and experience. The ground is strewn with blasted hopes and exploded theories. Half a century ago physicians bled for everything, later the lancet was obsolete, now it is again being rationally used.

The use of antiseptics has been carried to the top-most wave and broken in foam; yet we have learned that avoiding causes of disease is better than removing the disease after it has developed; that the practice of asepsis in medicine as well as in surgery is better than the use of antiseptics; that good hygiene is preferable to the best therapeutics.

Serum therapy more than any other one subject has during the past year occupied the minds of the profession.

It is with the utmost caution, that I approach this latest form of medication. The past year has brought forward a theory and practice, which is either a tremendous farce, or the greatest discovery, in any branch of medicine, since Jenner in 1798 proclaimed

to a plague-stricken world, the greatest scientific discovery ever made by man.

Toxin is prepared in glass vessels containing sterilized and peptonized broth which is infected with diphtheria bacilli from a fresh culture. This culture is kept warm for a month when the toxin is filtered off and injected into a healthy horse two or three times a week for about three months, when the animal is considered immune. From the jugular vein of this immune horse a quantity of blood is withdrawn and the serum from this immune blood called antitoxin is used hypodermically. It is manifestly important that the serum be a pure culture of definite strength; that the diagnosis in every case be a bacterial one; that the operation itself be performed under strict asepsis to avoid the introduction of pathogenic germs; and that it be performed at the earliest possible date in the history of the case.

Serum therapy is daily securing new advocates. If one-half of what has been written concerning Behring's discovery be true it is worthy a trial. Its advocates boldly claim that they can abort one of the most treacherous diseases in an incredibly short space of time; that the remedy is innocuous, and produces no untoward effect when injected into the tissues of healthy persons; that a diphtheritic patient's condition, as a rule, greatly improves almost immediately, the exudate subsequently peeling off, leaving a healthy membrane, and that all abnormal appearances often disappear within twenty-four hours; that it is a prophylactic for seventeen to eighteen days against diphtheria.

But, on the other hand, some careful observers after a trial of months under the best conditions, declare that the remedy does not fulfill the claims made for it; that its uselessness in secondary infections, in diphtheria of the bronchi, and the unfortunate after-effects, as purpura, albuminuria, hemorrhagica, nephritis, arthritis, and other evidences of systemic intoxication which at times have resulted in death, more than counter-balance its good effects.

Extraordinary enthusiasm has been shown upon both continents over this new departure in medicine, but a single year's experience is not enough time to determine its value. Enough has been proved to determine that it is worth a trial in connection with other better known remedies, and we may well content ourselves to await the dictum of time and experience.

The ultimate criterion must be a clinical experience covering a large number of cases under all the varying conditions and circumstances, and this can only be determined by careful work and the lapse of time.

The practice is still *sub judice*, and must pass the stage of empiricism before it can be adopted as a curative measure by the general practitioner.

In this present age, when new ideas flash around the globe with the rapidity of lightning; when the discovery of to-day is upon the lips of the world to-morrow; when countless numbers of men are vying with each other for the production of a panacea for some of the microbic diseases which have destroyed humanity for ages; we may well be cautious of our conclusions until enough time has elapsed to determine whether the lights in the horizon be a sign of dawn or simply a will-o'-the-wisp shining to lure the traveler from the true path into unknown depths.

In looking back over the wrecks of previous exper-

iments, the false hopes raised by the advocates of tuberculin, and the well-known fact that cases of diphtheria often recover with surprising rapidity with little or no medication, we can well afford to await the verdict of years of experience before pronouncing it a certain specific.

The numberless remedies which have been claimed for almost every disease may well be taken into consideration before we pronounce this a cure for a disease which has long baffled mankind.

The tendency of the profession against the use of antipyretic drugs, except in extraordinary cases, I regard as one of the recent advances in medicine. There can be no doubt that the use of heart depressants in fevers has been carried beyond the limits of reason, and the reaction has begun.

Tuberculosis is each year regarded more as an infectious and contagious disease, and the profession as a whole can not be too active in urging upon the public by all possible means the necessity of regarding it and guarding against it as such. The marvelous fact that persons are allowed to systematically travel over the continent carrying and spreading germs of a disease more fatal, more destructive to human life than any other known ailment, can only be explained by the ignorance of the public as to the danger of such a practice, and physicians have a sacred duty to perform in urging upon the laity the necessity of regulating this matter by law.

## LECTURES.

### LECTURES ON INTRACRANIAL SURGERY.

X.—THE OPERATIVE TREATMENT OF IDIOCY.

BY EMORY LANPHEAR, M.D., PH.D.

ST. LOUIS, MO.

Continuing the discussion of the operative treatment of idiocy I will first speak of

#### RESULTS.

The immediate danger is little. As Packard has said (*Annual of Medical Sciences*, 1891): "The procedure is a brilliant one, but of surprising ease in skilled hands." The primary mortality is about 10 per cent. since we have learned exactly how to handle these cases. There is commonly a considerable amount of improvement in many of the symptoms within a very brief period—an improvement that may last but for a few hours or that may be permanent; for example, if the child has been restless and inclined to sway back and forth with the peculiar cry of the idiot, there may at once supervene a condition of happy quietude; if of sufficient age, the patient may begin to notice things that have hitherto passed unnoticed—the general condition is very much as if there were a reversion to infancy; in a face heretofore void and expressionless, there may come a look of intelligence corresponding to that found in a baby a few months old; and shortly after the operation, if progress be favorable, there will be a more or less decided change for the better in the mental condition, as manifested in attempts at playing with toys, self-feeding, and by crying when spoken to harshly. This change I have seen to occur within a few weeks in cases of apparently hopeless idiocy. What the ultimate result will be, time alone can tell. In some cases there has been a marvelous amount of change—for a time—and then a lapse into the same old state.

## CASES.

As an illustration of the various types of idiocy I have operated upon, I will relate the following histories:

*Case 1. Microcephalic Idiocy—Operation—Improvement.*—Harry A., of Riverside, Cal., age 4 years, came under my treatment April 25, 1892. His general health was excellent. When he was about three months old, he had a severe convulsion, which was repeated in a few months, and since then spasms have occurred at irregular intervals, ranging from a few days to a week or two. The family history was good, except that the father and grandfather were inebriates; three brothers, aged 8, 12, and 14 years, were in perfect health. The child had never manifested any signs of intelligence, except to pay close attention to music, and to be attracted by bright colors. He always liked to make a great noise; had never made any articulate sounds, but always whined when not engaged in any noisy play. He could walk a few steps in a hopping sort of a gait, frequently falling; he never made any attempt to feed himself. Examination showed an expressionless face, evidence of only the slightest cerebral development; the frontal region somewhat deficient; occiput unusually well developed but the entire skull much smaller than it should be. The parents were told that very little could be hoped from an operation, but that it would be done if they so desired.

He was admitted to the hospital May 12, and was prepared for the operation in the usual manner. I made the first operation May 13, with the assistance of Drs. J. D. Griffith and J. F. Binnie. A large flap was turned back on the left side, including the periosteum. A half-inch trephine was applied, about one inch in front of the coronal suture; the bone was found to be unusually hard and thick. When the button was removed, the brain bulged prominently into the opening, but pulsated well. With Keen's forceps, a part of the skull was removed,—about three and one-half inches backward, and one and one-half inches in width. Hemorrhage was checked, iodoform applied freely, a rubber drainage tube inserted in the lower angle of the wound, and the scalp closed with continuous catgut suture, iodoform gauze, bichlorid gauze, cotton and bandage. Patient was put to bed at 10:45 with very little shock. At 12 he was very restless and crying piteously; therefore he was given:

R Chloral hydrat. . . . . 4.  
Elixir potassii bromidi. . . . .  
Elixir simplicis. . . . . aa 16.

Misce bene. Sig.: Half teaspoonful every two hours until quiet.

At 6 P.M. the temperature was 104.5, although there was no evidence of "shock;" he was sleeping, but very restlessly. He was ordered 3 grains of acetanilid, as a result of which the temperature was 103.5 at 11 P.M.

May 14 at 7 A.M., the temperature being still 104, he was chloroformed and the dressing removed. It was found that the drainage tube had slipped out of sight. The wound was therefore opened and the missing tube searched for; it was discovered pressed between the bone and dura behind the motor region, in the region of the supramarginal gyrus as nearly as could be determined. It was removed, the wound cleaned of blood serum, iodoform dusted in, catgut drainage inserted, and the usual dressings applied.

At 9 A.M. his temperature was 101 and he was more quiet; this prescription was given:

R Ammonii bromidi. . . . . .2  
Hydrarg. chlor. mit. . . . . .03

Misce et. ft. pulv. No. i. Sig.: To be repeated every two hours until bowels move freely.

At 7 P.M. the temperature was 99; patient doing nicely and sitting up in bed.

May 16. Doing well. Temperature normal.

From this time on, progress was uninterrupted, the child not being confined to bed even an hour.

The second operation was made June 17, by Dr. Griffith, assisted by myself. The same steps were followed as on the opposite side, except that catgut drainage was used instead of rubber. The temperature never rose above 99.5, and the dressings were not removed for a week. Convalescence was rapid and uninterrupted.

The boy improved rapidly in his mental condition; in

August my case record says: "This child can now walk in a natural gait. He is beginning to talk, saying, 'baby,' 'mama,' 'papa,' 'auntie,' 'good boy,' 'O God!' etc. He can now feed himself to a limited extent; pays the greatest attention to what is going on around him, and is playing with toys, something hitherto unknown to him."

The last report in 1893 from this patient showed even more marked improvement; and he had not had any more spasms.

A letter of recent date (almost three years after operation) from his mother states: "My boy is getting along finely now. His health is good, though he is still quite nervous and does not talk well yet. He can say a great many words distinctly, and has become one of the smartest boys you ever saw but he will persist in running away from home. He does not have his nervous spells (convulsions) now. He understands fully everything that is done and said and sometimes will repeat long sentences I speak to him, then laugh and run. I think he could talk if he wished to. He can sing any song he hears once or twice. He is very fond of music and has learned how to play on the guitar. He will play and sing for hours at a time. Dr. Lanphear, I will ever be thankful for what you have done for him."

The most remarkable thing about this case was the tremendous elevation of temperature after the tube slipped beneath the bone below the motor region. This, accompanied by the marked motor excitement, it seems to me, goes to support the assertion of Horsley, that there is a thermotaxic center in the motor region. The rubber drainage tube was used merely as an experiment, because there was an unusual amount of oozing; the experiment will not be repeated. A few strands of catgut have proved amply sufficient for drainage in a large number of trephinations I have done, and possess the advantage of not having to be removed.

*Case 2. Congenital Idiocy—Operation—Unexpected Improvement.*—Henry B., of Cairo, Ill., age 6 years, patient of Dr. J. C. Sullivan, presented for operation Sept. 22, 1892. Family history neurotic, epilepsy and insanity being present in near relatives. General health excellent; no history of illness except meningitis at his third year. He presented all the signs of the genitetic form of idiocy since his birth, and suffered from convulsive epilepsy for several years, the seizures increasing in severity and number until they were noted almost daily for some months prior to examination. My notes taken at the time read thus:

"Status Presens: Child well developed physically, except in the lower extremities; has all the symptoms of congenital agenesis of gray matter, viz., idiotic expression, prominent and brutal lips, irregular and decayed teeth, dribbling of saliva; he has the habit of sitting alone and swaying back and forth with a crooning noise, quite frequently throwing himself back on the pillow, screaming or moaning, tossing his head from side to side as if in pain; mental condition a perfect blank. The mother states that the child has never shown the slightest sign of intelligence, has never attempted to walk or to use his hands except automatically, has never tried to say a word, or appeared to notice anything that is said to him nor to pay attention to tones; at times she even thought him deaf because of his inattention to sounds. He has to have his food masticated and put far back into his mouth, as he has never learned to chew, and sometimes can scarcely swallow food, even liquids. He lies for hours, sometimes simply whining to himself or moaning. He becomes fretful when hungry, but is generally good-natured when kept well-fed."

The mother was told that this was a case that presented absolutely no hope from operation, as it was a variety that had never been operated upon so far as I could learn; and one that might possibly prove fatal. It was explained to her that there was the barest possibility that the irritation set up by the operation might produce a trifle of improvement, and she decided to take the chance; consequently the child was prepared in the usual manner for operation.

September 22. I performed craniotomy assisted by Drs. Thrush and Maxson, on the left side of head; the skull was very thick; the dura bulged strongly into the opening, pulseless, but upon enlarging the trephine hole to the usual dimensions, pulsation was established. In this case I opened the dura; decided paleness of the brain, and shallow sulci were noticed. Dura and scalp were closed with catgut and the patient put to bed in good shape.

September 23. Little shock was present; patient slept well; he was restless in the early morning, but food was given him, after which his actions were the same as if no operation had been made. Temperature 99.5.

On October 5. Operation made on right side of head. Bone greatly thickened but soft, was removed to the extent of 2 by 4½ inches. Dura not opened; no blood lost; duration of operation, twenty-eight minutes.

October 6. No shock; resting quietly; temperature 99; doing well; acting as usual.

October 7. No bad symptoms, restless manner entirely gone; has not cried once since operation.

October 17. Discharged from hospital.

December 26. Mother wrote that "Henry is improving in general condition; spasms are very infrequent and not severe, and he is beginning to pay attention to what is said to him, and particularly as to the tone of voice. When spoken to crossly he cries as would a baby six or eight months of age. He is learning to play with toys, and seems to take an interest in some things that are going on about him."

March 22, 1893, the mother wrote: "Henry seems altogether different. He has lost the restless way he had before the operation. He seems contented and satisfied everywhere. His feet are filling out, and he is getting a little use of his legs. His flesh is firmer and more solid. When he is hungry he hollers, 'Eat, eat, eat,' and, Doctor, his ways are all so much like a 1 year old baby's. He tries to climb up by chairs and stand on his feet, and I notice that if he happens to fall when climbing up, he is careful to hold his head and try and not fall again. He does not put his hands to his ears and head as he did before the operation. He gets amused with playthings and seems to enjoy himself. He seems to grow stronger in every way, but does not improve about walking. Still, he wants to hold to everything that he can reach. He eats heartily and sleeps well. His arms and body seem to be very strong, and his lower limbs are improving also. If they were only strong, I think he would walk soon. The way I first noticed his flesh was getting more solid was when he would kiss me, he would press his cheek against my face and it felt so much harder than before you ever saw him, so I felt of his arms and legs, and I know that he is gaining in flesh.

"Well, Doctor, I have been asked more questions about him since his operation; it seems to be a miracle the way he has improved, so everybody says who sees him. He blows his lips like a child just learning to talk. He can say four words right plainly, and he often does what I tell him to do and seems to understand me. I can say God bless you, and hope that some day we can send you money."

Dr. Sullivan recently informed me that progress is still satisfactory in this case—decidedly far more change than he ever expected to see; and that the present condition is certainly much better than could possibly have resulted from mere educational efforts.

This was a typical case of congenital idiocy, and as pronounced as any that has ever come under my observation; yet if the reports can be regarded as true, the amount of development since operation has been more phenomenal than that of any case that has ever been reported; which leads to the conclusion that operation is of some benefit in cases of congenital as well as in microcephalic idiocy. It does not seem to me that simply the increased efforts to teach the child could account for such marked changes; certainly the craniotomy was responsible for checking the epileptic paroxysms which were such a distressing element in this case.

*Case 3. Epileptic Idiocy—Removal of Angioma—Some Improvement (Temporary).—*Roy L., of Independence, Kan., age 12 years, was sent to me Nov. 29, 1892, by Dr. A. McCully. He was well developed; general health, good, and in excellent bodily condition. As a baby he was excessively nervous, but otherwise well, and was unusually intelligent up to the age of 3½ years when he began to have "night terrors," and a few months later developed epilepsy. Since then his mental development was very slow. Examination showed patient to be suffering from epileptic idiocy (the idiocy being of high grade); his language was fairly good, though sharp and quick, and only the most infantile forms of expression were used. His right side was far less developed than his

left, and the spasms were always on the right side of the body. He had convulsions very frequently at night, and once in four to six weeks had a hard convulsion in the daytime, the diurnal attack being upon both sides of the body. He had to be watched constantly because of a developing viciousness. He could intimate his desire to micturate and defecate, but could not unbutton his clothes. He had absolutely no idea of right or wrong, the moral sense being totally absent. He played with the usual toys, was passionately fond of music and could readily learn to whistle a tune. Operation was strongly advised, for the cure of epilepsy, but with little encouragement as to mental improvement.

On December 1, I made the usual operation. With the gouge a cut was made through the skull to the dura just at the margin of hair on forehead, then the opening extended over the frontal and motor regions about two inches wide and four inches long. Over the leg and part of the arm center there was found an angioma measuring about one and one-half inches across. This was excised with much bleeding as the veins in the dura were almost varicose in size, and had to be ligated with catgut. The dura was sewed with catgut, iodoform put in, catgut drainage inserted, catgut sutures in the scalp, and the usual dressings applied. Duration of operation, one hour and ten minutes. In the evening he was resting well; temperature 99.5 and no evidence of spasms. Recovery from the operation was speedy and uneventful. He had a convulsion December 5, but no more up to the time of his discharge on Dec. 21, 1892.

May 10, 1893, Dr. McCully informed me that reports from the patient indicated much improvement in the mental condition. Language was being acquired with marked rapidity. Education was already begun with gratifying success, and there had been no return of convulsions since discharge from hospital. But unfortunately the boy could not be sent to Wilber's School for the Feeble-Minded, at Kalamazoo, Mich., as I advised; instead he was placed in the Kansas Insane Asylum at Osawatimie. The Superintendent, Dr. L. F. Wentworth, lately wrote: "He now has frequent attacks of epilepsy; many of his seizures are very severe and the number sometimes reaches as high as six, eight, ten, twelve or even fifteen in a day. His mind is therefore weak and childish and there has been no improvement in this particular since he came to the institution."

This was a typical case of idiocy due to convulsive seizures, I believe, and may be taken as an illustrative case of what might be accomplished by operative procedures in cases of suitable character; I am sure that the general epilepsy which caused the mental deterioration might have been prevented by earlier recognition and operation at a time prior to such marked impress upon the whole brain. It is a case which emphasizes the absolute necessity of early operation in Jacksonian epilepsy. Of course no man can make a diagnosis of angioma of the dura before trephining, so that in a measure such operations are exploratory; but none the less indicated.

*Case 4. Traumatic Epilepsy—Operation—Death.—*Jay B., of Guthrie, Okla., age 6 years. Family history and previous health excellent. Up to the age of 3 years he was in good health and as bright as children usually are. He then fell down a full flight of stairs and was picked up unconscious. The physicians called did not think the skull fractured, and prescribed a placebo. The unconscious condition continued for forty-eight hours. Upon return of consciousness the baby had a convulsive seizure like epilepsy and seemed "dazed." After this time convulsive epilepsy manifested itself by almost daily spasms and by mental deterioration. At the time of examination, Feb. 12, 1893, a condition of idiocy was found present; no speech, no attention to what was said or done, restlessness pronounced and spasms frequent, one occurring during examination. Upon the head over the motor region, there was a great prominence with roughened margin of old fracture apparent through the scalp. Operation was advised. With the assistance of Drs. Maxton and Truex, on February 15 I removed a button of bone with the trephine, and found the skull to be one-half inch in thickness just behind the parietal eminence. In front of this there was a depression with very fine fibrous tissue overlying the dura, with the thickened and roughened margin of the old fracture sticking up at its edge. With a Hoy's saw and chisel the protruding mass of bone was removed, as shown by the accompanying specimen:

There were two large sharp osteophytes projecting inward more than a half inch, removal of which caused sharp hemorrhage for a moment. The adhesion between the roughened, depressed bone and the dura was very firm. After removal of the bone the dura was opened and the brain found apparently normal in appearance and consistency, so the dura was quickly closed and the operation brought to an end. This was especially necessary as the child came near dying upon the table from some unexplainable cause—possibly from shock. In the evening the patient was resting easily; no convulsions; temperature 100; some shock, but apparently not severe.

February 16. Patient passed a quiet day, eating well and sleeping soundly; no convulsions during day.

February 17. In the early morning the child gave a scream, went into a most extraordinarily severe convulsion, ceased breathing, and died.

The post-mortem revealed no reason for the death of the child, and it is hard to account for the fatal termination. There was, as already stated, complete recovery from shock to all external appearances, and at midnight the patient was reported as out of danger. The house surgeon, who was present at the time of death, regards the fatal ending as simply asphyxia from the prolonged continuation of the tonic spasms of the muscles of respiration during the convulsive seizure.

'This was a case that should have given excellent results, and I should not hesitate to advise operation in every similar one. The size of the piece removed may seem extraordinary to those unacquainted with

Figure showing shape of piece removed and space in center. Actual size. Thickened and depressed bone; roughened and thinned bone, and small osteophytes; adhesions.

work upon the head, but I have frequently removed pieces of even larger size than the one here shown, without fatal termination. I am inclined to believe that the house surgeon is correct in his opinion as to the cause of death.

*Case 5.—Hydrocephalic Idiocy—Operation—Mental Improvement.*—Lydia W., age  $4\frac{1}{2}$  years, Kansas City, Mo.; had always been healthy excepting the head trouble, though rather weak and anemic. She was apparently normal at birth and until the fifth month was not unlike other children although her head was regarded as rather large and fontanelles had shown no signs of closing. About the end of the fifth month she began having slight spasms, the head drawing to the left; soon afterward her head began increasing in size rapidly and she soon had well-defined hydrocephalus, from which she became totally idiotic; she had severe convulsions occasionally, and from five to ten light ones daily. Examination showed a head twenty-two and one-half inches in circumference and sixteen inches from ear to ear. She had marked protrusion of the eyes and some strabismus. At the time of examination the head was hard and the sutures closed, though for long they remained widely separated and projecting as ridges beneath the scalp. Operation Nov. 28, 1891, after careful preliminary treatment. Scalp opened by large horseshoe flap over left side; button removed with trephine; skull found eburnated but not more than one-thirty-second of an inch in thickness. The opening was enlarged to about one and one-half inches by three inches. The dura was thin and translucent, showing a large amount of fluid below, but no fluid was withdrawn; the scalp was stitched back into position and the wound closed. Little shock.

Duration of operation twenty-six minutes. In the evening the patient was resting well and smiling; had been very quiet during the day and slept some. No vomiting. Temperature 100 degrees. On November 29 the patient was in good condition, eating as usual. Temperature 99. November 30 she was in as good shape as before the operation. Temperature normal. On December 6 the dressings were removed and healing by primary union found. A hollow needle was thrust through the scalp and dura and three ounces of serum removed; antiseptic dressings were then applied. A slight convulsion was noted afterward. December 10 the puncture was repeated. No convulsions were noticed, but there was some continuous leakage after withdrawal of the needle. On December 16 more fluid was withdrawn, though constant drainage had necessitated changing dressings. December 20 three and one-half ounces of serum were removed and one-half ounce of iodoform emulsion (10 per cent.) previously sterilized, injected. A slight convulsion followed. January 16, the patient was rapidly improving. Withdrawal of fluid and injections were repeated.

The people now disappeared and the case was never seen again; but friends of the family recently reported marked improvement in the mental condition—they called it a "cure," the pressure symptoms, convulsions, etc., having disappeared. The mental condition is said to be about like that of a child of 3 years.

*Case 6.—Inflammatory Idiocy—Operation—Death.*—Nicholas L., of Selina, Texas, age  $4\frac{1}{2}$  years, came under my observation March 6, 1892. Family history was excellent. The health of the child was good until the age of eighteen months, at which time he was as bright as any baby of that age and was learning to talk. An attack of meningitis occurred at this period of his life, presenting the typical features of acute inflammation of the meninges. It was followed by complete loss of all intelligence, and the child remained a perfect idiot until date of examination. After securing the history and making a careful examination, operation was advised against; but the parents insisting, the experiment was made. A very large piece of skull was removed from over the motor area, extending forward into the frontal region. There was great thickness of the dura, and upon incision a cloudy infiltrate was noted in the pia. Upon attempting to raise the membrane from the surface of the brain, adhesions were found everywhere over the frontal convolutions, but not in the superior parietal ones; hence the impairment of intelligence, but non-involvement of the motor functions. The adhesions included the speech centers as well as the convolutions situated more anteriorly. As nothing could be done to secure improvement in this case, the dura was closed with catgut and the scalp united without drainage, there being no hemorrhage of consequence.

Death fortunately followed two days later from meningitis. I characterize the fatal termination as "fortunate," because the operation certainly would not have done any good. It is possible that some cases of less severe degree might be benefited from breaking up the adhesions; but I must strongly advise against operation in any case known to be of inflammatory origin. I have thought it best to report my fatal cases lest it might be inferred that there is but trifling danger. In twelve operations for idiocy I have lost three patients—a mortality of 25 per cent. My first fatal result was due to the use of the chisel and to the fact that I operated upon both sides of the head at one operation—a thing I would not do now. This case is reported in full in the *Kansas City Medical Index* of February, 1893.

Aside from the case of Nicholas L. just reported, my operations have been limited to microcephalic, traumatic, congenital and hydrocephalic classes; the remaining cases are as yet too recent to permit legitimate conclusions to be drawn.

#### CONCLUSIONS.

From a thorough study of the literature of the subject and careful observation of my own cases, (which certainly have not given as good results as Lannelongue's reports led me to expect) I have reached this conclusion: the field is a limited one

yet operable cases are so very numerous, the mortality so low, the future of every case so barren of hope without operation, that I can not but believe we are justified in still continuing the experiment. But we should make it an invariable rule to carefully explain to the parents that the operation is a purely experimental one, point out the dangers to be encountered, very plainly state that the results thus far observed are not sufficiently flattering to warrant us in recommending operation, and that we can promise absolutely nothing except that the mental condition can not be made worse. If in the face of these statements the parents insist on having the operation done, we are certainly justified in undertaking the work in the most careful manner possible, to give the poor unfortunate the one slight chance of relief from an otherwise impenetrable darkness.

## ORIGINAL ARTICLES.

### CLINICAL REPORT OF THE PAST TWO YEARS' WORK, AT THE ROCHESTER STATE HOSPITAL FOR THE INSANE.

BY R. M. PHELPS, A.M., M.D.

ASSISTANT PHYSICIAN ROCHESTER STATE HOSPITAL FOR THE INSANE;  
MEMBER AMERICAN NEUROLOGICAL ASSOCIATION, AND OF THE  
MEDICO-PSYCHOLOGICAL ASSOCIATION.  
ROCHESTER, N. Y.

Much of valuable clinical material is incident to every hospital year, and would seemingly be fitly gathered and rendered available for study and comparison with other hospitals of its class, as well as by physicians generally. As a lengthy list of cases would be tedious, we would frame a review of the two years' work, by touching upon those topics and cases which rise above the level of the daily routine, so familiar to us all. First, we would add some explanatory comments upon the clinical information, designated by the statistical tables of our report. Every hospital report has accompanying it, a list of statistical tables. As every official doubtless knows, this information is necessarily very defective.

1. *The Recoveries.*—Dr. A. A. Christian, of the Pontiac Asylum in an article (*American Lancet*, 1894, p. 161) analyzes with great pains a series of cases to show that a large number of so-called "recoveries" speedily relapse, and are more or less recurrent in character. That another proportion is not fully recovered, as shown by the test of ability to meet their home duties. He finds, after rigidly excluding such cases, only about 17 per cent. of true recoveries to admissions, in a considerable number of cases studied with painstaking care. Dr. Burr, Superintendent of the same hospital, in 1893 urged this same matter before the Association of Superintendents. Indeed, Earle's book on "The Curability of Insanity" covered a considerable part of the same ground some years ago.

Dr. Burr urges the formation of tables which shall be more accurate; but if by accuracy is understood the following of the case for five years after dismissal, it would seem to be somewhat impracticable, approximations being all that are possible any way. Tables call for designation of cases as recovered or not, at the time of dismissal. Public reports, moreover, have to be made regularly, and one can not wait years before making a diagnosis for them. The central idea

of most value is, that the decision "recovered" or "not" is in each and every case a *matter of judgment*, and that there is no way of having it otherwise. That the person making the table can include doubtful cases as "recovered," or call some recovered whom others of equally good judgment would exclude is true. It is, however, possible to draw up some lines, forming a basis of judgment, which shall be used by all making such judgments, and therefore a common standard be secured. This is the aim as I take it, of the resolutions adopted by the Psychological Association. The personal quality of painstaking judgment in the one making the decision, and a common standard seem to be what are required. To follow patients, however, after leaving here for all parts of the State seems hardly practicable, and most of them have no friends with sufficient judgment to make an accurate report.

Aside from any "judgments," however, our total of curable cases admitted (which as Dr. Chapin suggests in his late report would be those selected by a general hospital in its estimate of results) is at a close approximation and excluding inebriates, about 266 out of a total of 621 insane admitted. This, however, leaves out of account chronic mania, and chronic melancholia, as well as the senile degenerations, paranoia, paresis and others. But these cases designated as chronic, (over one year's duration) occasionally recover. Adding these to our list, then, we have a total of 397 out of 621, to be considered upon admission as recoverable cases; leaving 214 or 34 per cent. who would be considered incurable usually on admission. Of these 397, some are recurrent cases. It might be said in general, then, that 35 per cent. of the cases admitted to this hospital are clearly incurable at the time of admission. A personal canvass of each case, however, reveals that most of the so-called chronic cases are also practicably incurable, and therefore 50 per cent. would be more near the true figure.

A caution is needed here; by "curable" we do not mean *treatable*. General paretics and others need treatment. Probably from 70 to 80 per cent. of cases need treatment, slight or great, upon their admission, although later they may drift into a chronic and stationary state.

2. *Age of Admission.*—Sinkler, Harriet Alexander, C. K. Mills, Sarah Weldt and others, have in the past two years had their interest excited, and have gathered some cases of insanity under 10 years of age. It is admittedly, however, rare and tends toward epilepsy or defectiveness. The great tendency of insanity is to wait toward the decline of life. As if forsooth, the impetus of natural endowment or constitution carried a man past the most vigorous time, only to be caught as the powers of life naturally begin to decline. The average age on admission here of over three thousand cases, is approximately 38 years. The average of cases coming into this asylum, then, are at what may be called the beginning of the decline of life.

3. *Causes.*—In our table of the causes alleged by physicians and friends on admission, there is necessarily so much of error as to make it of little value. We do not know enough of the history to correct more than a few of these causes, and the examiners are apt to put down impromptu, that which has been the last stirring event, or most prominently suggestive or suggested by the relatives. This is copied in by us,

only correcting it as our knowledge will occasionally allow. But, aside from all this, it is to be remembered that it is rare that *one cause alone* is responsible for the disease; and moreover that a clear distinction as possible is needed between predisposing and exciting causes. For this period we have carefully considered these causes, and have tried to classify them so as to suggest prominent and leading causal factors.

We firmly believe that *heredity* is the chief predisposing cause. Heredity must needs have no narrow sense, however. It must be broadened out so that it means both, "if the patient is peculiar, eccentric or partly demented, and the son goes to the asylum an acute raving maniac and, on the other hand, if the parent be a raving maniac, and the son have only the quiet unnoted feebleness of mind. But in all statistical tables neither of these cases would find any recognition, nor are many others of indirect heredity recognized at all." These tables of heredity only recognize insanity in a near relative, so gross as to be well known. Indeed a large number even of these are denied to us.

Recognizing an inherited or inherent brain and nerve instability as the predisposing cause, then we feel that it must almost necessarily be present to allow for other causes to act. Probably this is the most important topic in our list. It would seem, in looking about in the world, that you could sum up and pile all of the other causes on one man and he would not become insane because he had *not* this inherent instability. Without being able to define this most essential element in the cellular nervous structure, we would yet say that it is to an extent recognizable in the same way as is the tendency to consumption; in the consideration of which it is fully as manifest that some men will go through all of the causes and never have the disease, consumption. These latent, inherent predispositions of the body are hard to define, even with the use of modern terminology; yet need not be therefore denied. But heredity of the indirect though real form, can not be reduced to statistics. Of direct heredity, we find 84 men and 58 women, out of a total admission of 374 men and 247 women. This is probably much too low even for the direct form; but incomplete information is not preventable.

4. *Forms of Insanity*.—It is seemingly very important to have a table of diagnosis of the forms of insanity; but a close thought would reveal that it is really, however, not so important as it is to have *uniform methods* of naming the form among different hospitals. But we doubt if any two hospitals for the insane in the United States have exactly the same list of names. The distinctions between the different forms, even if made by experts, being in many cases transitory or unessential, it is the broad types which the far-seeing alienist wants; not particular names. There is a type of "general paresis," and particular cases conform with more or less closeness to it or lean over toward other types. There is the type, "senile dementia," and special cases conform with more or less closeness to this type, or vary toward the paretic or apoplectic type. There is the type, "acute mania;" and only a few cases adhere closely to it, many having a quite distant approximation, while some are on the border line toward melancholia or senile dementia; and so on through the whole list. The sharp lines drawn are all in our imaginations. They are arbitrary. The cases are not fenced off

into pens, as we would fence a drove of animals, but are scattered over the whole field, and each may imagine his own fences arbitrarily. However, one set of boundary lines may be far better than another, and we should, as far as possible, select broad fundamental differences. For example, youthful cases are apt to approximate the defective or feeble-minded class; having superadded variable and vacillating exacerbations, upon a gradually increasing mental trouble. This is a far more fundamental distinction than is the transitory and varying maniacal or melancholic behavior of any particular time. "Pubescent insanity or developmental insanity" are names we have used to designate these cases; names more true than those of mania or melancholia.

The distinctions, "acute" and "chronic," are only arbitrary, and are by some discarded altogether. To call all cases under one year's duration acute, is a common method. If some committee could be appointed with authority to enforce the use of some list of names, we all ought probably to sink our preferences in favor of uniformity. Of the acute manias we have made two classes; the acute disease which rises to a climax like a fever, with its typical excited incoherent speech and conduct. A second class might be probably called sub-acute; it includes the exacerbations of mildly affected cases; very slowly progressing cases approximating chronic, yet not over one year's duration as reported by relatives and having no acute rise as far as known. Of these two forms the former (the only true acute mania), we have in a total of 621 admissions only 54 cases as shown by our tabular analysis. Moreover, even of these 54, only about 20 were of the extreme maniacal type, with flushed face, trembling incoherent speech, etc., approximating the type, "acute delirium." Adding to these the 130 cases of *acute melancholia*, and we have as approximately the sum total, 163 cases in 621, in which insanity was distinctly an acute disease, rising to a climax, and unassociated with any gross brain lesions, like those of atheroma, paresis, senile dementia, etc.

"Syphilitic dementia" designates the dementia produced by syphilis. If a mania or melancholia is accompanied by syphilis it goes among the other manias, and syphilis is put down as a cause. This is due to the predominating tendency toward dementia as a sequel to syphilis.

"Choreic dementia" is subdivided into the dementia of the adult progressive chorea and the "juvenile" form, according to the very different characters of chorea producing the trouble.

The melancholias are subdivided into the agitated and stuporous forms, to meet the usual distinctions made as to behavior.

"Puerperal" is put down among the list of causes, and the manias so produced are included among other manias; this seeming to be the most just and accurate way.

5. *The Causes of Death*.—These cause some perplexity. It would seem best to have the immediate and fundamental causes given separately. The word "exhaustion," perhaps, causes the most question. Exhaustion usually means tire from activity; in insanity it frequently does not. For example, in general paresis or senile dementia, it means a gradual deprivation of central nerve power. The cortical impairments of these troubles easily suggest the cause. The substitution of the immediate for the fundamental cause

is avoided as much as possible. "Heart-failure" was, however, necessarily used in several instances; for example, one old man failing somewhat from senility, died suddenly and quietly in bed a half hour after eating a good supper. He seemed well, and as no autopsy was held, and atheroma did not seem prominent, "heart-failure" was designated as the cause.

"Acute periencephalitis" has been used to designate the cause of death in cases following H. C. Wood's designations. The five cases so named could be termed subacute meningitis doubtless, if we so wished. They seem to fall halfway between acute delirious mania (or the "acute delirium" of recent writers) and ordinary meningitis. No autopsies of these cases were secured. Among the total number of deaths of 131, we find that 40 are from pulmonary tuberculosis, and 39 from general paresis. Epilepsy claims 8, apoplexy 4, senile dementia 13 and brain disease 11.

6. *Occupations.*—The occupations are systematized and condensed on the fundamental lines of a probable leaning toward mental impairment, and do not well sustain the idea of brain strain or mental overwork as a factor in producing insanity. A preceding defectiveness is the most prominent element.

Leaving now the statistical tables, there are other subjects which have received especial study and consideration during the past two years. "Phthisis and its relation to insanity" was quite thoroughly looked up by Dr. Sarah L. Phelps. "Strychnin—the use of in inebriety," was made the subject of an experimental study. The general consideration of "Inebriety" as a curable disease was considered. "Hereditary chorea," and its relationships, and "Periodicity in insanity," were made subjects of articles. Of phthisis or pulmonary tuberculosis, Dr. S. L. Phelps, from analysis of evidence, concluded that there was no mysterious connection with insanity; that it produced no especial form of insanity, nor did insanity, except in the various *indirect* ways, produce the lung troubles. Confinement, inactivity, extremely careless habits of neglect, extreme neglect of all voluntary sanitary measures, predetermining toward tuberculosis, producing a somewhat larger proportion of cases than among the outside population, even if among selected people of the same ages. Looking over our record we find that we have had 40 deaths from tubercular disease of the lungs, during the past two years, out of a total of 131.

Dr. Channing recently (*Boston Medical Surgical Journal* July 19, 1894) assumes tuberculosis to be the cause of insanity quite definitely, following Clouston in his ideas of the disease, and asserting it to be about three times as prevalent in asylums as among the sane. Later study, however, it seems to me shows many corrective facts. The average age on admission to hospitals for the insane is here about 38 years. Statistics among the sane usually include all ages, of which the total adult population is but a fraction. Again, most cases of tuberculosis in asylums are among melancholiacs and demented, who sit inactively for months, and neglect, as far as they are personally concerned, nutrition and exercise, which are the two main preventives of the progress of tuberculosis. Sane people do not so neglect themselves. Again, the insane are careless as to cold-catching and exposure; the sane are not. The insane have a tendency toward sedentary life, as in most cases the sane do not.

Dr. Channing found the average number of deaths

resulting from tuberculosis among the insane, to all deaths, to be about 16 per cent. which is about our average here. This is hardly, however, three times the proportion of deaths from tuberculosis outside, which for persons at adult age, say from 35 to 45, the average age of the insane seems to be nearly (perhaps a little over) 10 per cent. while for all ages it seems to be only about 5 per cent.

Of evidence of tuberculosis as the cause of insanity, we can add little that is new from this two years' record. In two cases of admission here, tuberculosis was present on admission, and progressed coincidentally with acute typical mania, both dying in a few months. One was a case of a girl aged 18, who had been some five years previously treated here for a similar attack, and had quite fully recovered. Tuberculosis was in the family history. She failed rapidly, dying twenty-three days after admission. Another, an old lady, aged about 61, approximating somewhat the senile age, yet had an attack of quite typically acute maniacal behavior, the second one in her life, it leading on rapidly to death from pulmonary tuberculosis in the same manner as the preceding case, about six months after admission. Among the forty cases of deaths during this period these are the only two, however, suggesting in any way a causal connection, and we fail to see any distinct evidence, more than a coincident one, in these cases. Ordinarily these consumptives are quiet melancholiacs or demented. In the forty cases mentioned, twenty-six were melancholiacs and nine terminal dementias; one, chronic mania; one, mania a potu; one, morphinism. Only four cases were at all active ones.

*General Paresis.*—General paresis is a subject always calling forth peculiar interest. As will be seen, we have thirty-nine deaths from this trouble, this period; thirty-three men and six women. This is a large and important element in our death causation. More sad still is the fact that once diagnosed, treatment will only delay the fatal termination, never prevent it. It receives extended study, however, not so much in hope to cure, as to study its forms and causes and to secure such thorough knowledge as to prevent to some extent its invasion. The causation is still somewhat vague. Continued study only goes to show that though syphilis is considered the most powerful cause, that all intemperance and excess seem to help its onset. Too little attention, perhaps, is paid to the element of *predisposition* in this case. For it is evident upon a broad outlook that while the causes of paresis act upon an immense number of people, only a few of them develop the disease, general paresis. Lack of space prevents giving a synopsis of the thirty-nine cases.

Under general paresis it should be said that more and more cases have come to be included, which once went by other names. Senile cases of strong parietic form, also gross brain lesions of various kinds, which have tended to produce the same sluggish parietic state, and even to have considerable of the same progressive tendencies, tend to receive the name. We have not space to review the thirty-nine cases which during the past two years have proved their diagnosis by a rapid progression and death, but will mention a few summarized facts concerning them.

Of the thirty-nine deaths, thirty-three died in exhaustion, by which is meant a steady progressive failure, without other special bodily trouble. One

died from choking, one from meningitis, two died from convulsions of an apoplectic form, and one from a series of convulsions, simulating status epilepticus. One died with erysipelas.

Concerning convulsive seizures in general, it is to be said of the thirty-nine, that nine had at some time during the course of their trouble, convulsions of a decided character, while seven more had "spells" which approximated unconsciousness, with or without convulsive movements. Their average age on admission was 41 years; the average duration of their stay here was one and one-fourth years. To this duration, however, we would add the probable average duration of each case before being admitted to this hospital, of from one to two years.

*Chorea.*—Of chorea we have had examples of the varied forms; have had two cases in youth, (one aged 18, another 20) in which the mental weakness and confusion of mind was coincident with the chorea, seemed to be caused by it and receded with its recession. These we have designated as choreic insanity "juvenile," to differentiate it from the radically different adult form. We have had two more cases of the adult progressive chorea with choreic dementia, one of these giving a vague history of "hereditary chorea" form. We have had two marked cases of the so-called "post-hemiplegic chorea," also one case of most extreme chorea with imbecility.

There was also one case of a sudden outburst of chorea of most extreme form, coming on within two or three hours at the beginning of a relapse of typhoid fever. The mental state in this latter case was a hysterical delirium, culminating in this choreic attack with quite complete helplessness. This case, a young girl of about 20, recovered very perfectly.

The most striking case of chorea was one of acute form, producing death, coming on about a year after childbirth. This case is published elsewhere, (*International Medical Magazine*, February, 1895) as also a case of prolonged lethargy of nine months duration, and one of adult bilateral athetosis, idiopathic in character.

*Paralysis Agitans.*—Two cases have been admitted during the two years just past; one a woman aged 70, having dementia of the senile, weak, childish form, without defined delusion. The other, a man of nearly the same age, also demented, with delusive ideas feeble in character. It is doubtful if a special kind of insanity should be so named; it is probably enough to record paralysis agitans as the cause, with the mental reservation that it is perhaps merely the concomitant element.

*Jacksonian Epilepsy.*—Jacksonian epilepsy, in the sense in which is meant an epilepsy with some localizing motor spasms, is rare in the advanced cases presented here. One case in which epilepsy followed a gross brain injury of seventeen years ago presented itself. This man, in spite of a trephining, had been epileptic for some seventeen years; had been at times somewhat actively deranged mentally, but usually only when he drank, which he did at every chance. He recently, while here, began having fits more severely and showed more of mental derangement, and after some of them there remained a numb feeling, a lack of power in one hand, with some occasional involuntary motions of the fingers. These motor symptoms in a general way, corresponded with the locality of the scar upon the opposite side of the head. Dr. Charles Mayo on consultation agreed to

operate. Before consent of relatives was obtained, however, patient went into a status-epilepticus, out of which he was brought by the use of nitro-glycerin. Was then in a semi-delirious condition. Operation was successful; scar was found to be not all bony, and directly under the scar was a cyst holding about two ounces of fluid. Patient had one fit the next day, but in the course of about two weeks recovered his ordinary mental state, and eloped from this place reaching home safely.

*Gross Brain Injury.*—A man was admitted here, in 1893, with a large irregular opening of nearly two square inches in the skull, above the inner corner of the right eye. This had been produced by a supposed intentional suicide, with a gun. The brain lay exposed and pulsating to the view, though covered by a coating of purulent deposit. A probe reached indefinitely back along the surface of the brain; brain matter to the extent of a teaspoonful or more was said to have exuded, and was removed after the accident. He was obliged to keep his face forward, for the drainage of what was practically a large open abscess cavity. He began to have some fever, went to bed, seemed to be failing, and his people were sent for on the strength of a bad prognosis. They took him home, however, and a month later sent for his discharge, on the plea that he wanted to do some business. He had, while here, no motor symptoms or paralysis, and was only a case of ordinary mild melancholia. If accurate data could have been had as to amount and exact location of the brain matter removed, the case would have been of considerable value.

*Acute Alcoholic Dementia.*—This is the designation of one of our cases, and would be of one more, except that the second one came upon an inebriate warrant. As the term might be perhaps misleading, I give the case briefly: a man, aged 50, was here several months as an ordinary inebriate. He went home on trial, and a few months later was committed as insane. He was then found to be completely demented, and in a condition closely resembling general paresis. His face was blank and smooth in the extreme; his memory almost gone, talked fairly free and very peculiar; polite in form, although his ideas were mostly imaginary. Speech was hesitating but not much slurred. In this state he has continued for the eight months which have since elapsed. The causation in this case was acute, and the result is quite different from that of a case of chronic alcoholic poisoning, and therefore we have given the distinguishing name.

*Primary Dementia.*—This is used to signify a number of cases in which there is a slow growing demented condition, such as is produced by alcohol without any especial mania or melancholia. In some cases, however, there seems to be no alcoholic history or other like causation upon which to base the designation. To these we have given the name, "primary dementia" in that we have considered them too different to come truly under any one of the other designations. These cases are usually of adult life, and could not, therefore, as would be otherwise quite possible, combine with the pubescent cases. These could be forced into other classes by distribution, but it would seem could not be done without obliterating important distinctions.

*Use of Strychnin in Inebriety.*—Among other subjects which have received special study during the past two years, the preventive action of strychnin

upon inebriety was studied by an experimental trial in twenty-five cases, in the firm belief that this was the active element in Keeley's cases. The results were published. Though averse to having any seeming connection with Keeley's methods, yet of its possessing an action above any suggestive one, there seems to me to be no doubt. That the suggestive element must be relied on to carry on the effect, however, there is also not much doubt, as the drug action is only a temporary one. That it can be asserted to be logically the best drug for the purpose is, however, in my opinion very probable.

Our opinion as to the value of hypodermic injections of strychnin in combating the craving for alcohol, was practically re-affirmed two years later by Dr. Breed, (*Philadelphia Medical News*, April 7, 1894) who outlines in a similar manner its direct value above that of a suggestive one, in annulling the appetite of the inebriate, "and that without the least effort on his part." Its strong tonic action is also dwelt upon. Dr. Breed, however, was a little too near to the first enthusiasm of the immediate effect of the hypodermics to judge conservatively of their permanent value. He assumes inferentially, moreover, that the drug effect is a permanent one which seems to me a great error. Suggestions, fear and moral effects must keep up the waning influence of the drug. (I have often wondered if the administration of the drug could be kept up either in small doses or in an intermittent way, so as to insure permanent effect.) Dr. Breed also speaks of the hypodermics of strychnin as if new, whereas during the past two years it has been frequently mentioned, and our own idea two years ago was gotten partly from the references to the records of Russian and Italian physicians, the experience of whom I believe goes back as far as 1880, and from whom I suspect Keeley to have adopted and developed the idea. Partly also my incentive was from Dr. Gray, who claimed to be using it in his Sanitarium at La Porte, Indiana, and whose methods rather than Keeley's were the ones that I adopted. We used here the nitrate of strychnin, especially prepared by Eli Lilly, for such treatment.

Partial or modified responsibility. This somewhat philosophical subject, running out on theoretical grounds, yet being of far-reaching practical value, the "partial" or "modified" responsibility of some people, was strongly advocated as needing a recognized standing in an article before the State Medical Society this year. The connection of Bright's disease with insanity, strongly and ably advocated by E. D. Bondurant of the Tuscaloosa Asylum, stimulated us to an extra effort to see if we could justly admit ourselves to have overlooked such fact. Aside from the consideration of any theory of connection, however, we could not find any such facts of albuminuria and casts as he detailed. We found even after some selection of cases, only about 13 per cent. of cases; and probably we would average not over 5 per cent. of the admissions; whereas he found about 85 per cent. in consecutive examinations, some 50 per cent. having both albumin and casts. Drs. Bennett, Tuttle, Christian, Amelia Gilmore, Babcock, Norris and others have all studied the subject with varying results. Landon Carter Gray's recent article also falls in the same line.

*Treatment of Choking.*—In connection with Training School work, there has originated a peculiarly useful mode of treatment in cases of choking which,

so far as I have noted, is not mentioned in any text-book on nursing. In one case of choking by meat, when the finger could not reach the morsel, and the man was becoming comatose before my eyes, it suddenly occurred to me to reach with thumb and finger deep down behind the sternum, to pinch the windpipe and strip it upward; thus carrying the contents up into the throat. It was easily and promptly executed; the meat taken from the mouth, after which three minutes of artificial respiration brought him to life. So simple and fairly sure is this procedure that I should now think that one of our nurses was neglectful of duty who did not try it in any similar case.

*Hypodermics of Nitro-Glycerin in Epilepsy.*—In last year's literature several references were found as to the value of hypodermics of nitro-glycerin in checking the convulsions of epilepsy. Upon having a case of status-epilepticus in a young girl, in whom a comatose condition had been present for over twenty-four hours, in whom the temperature had reached 104 degrees and who was considered as surely going to die, the idea of trying these hypodermics was considered. The very first one was followed by a reviving effect, and a continuation brought her from the coma and fever to her usual condition in, approximately, about four days. She has been as usual since. This seems to me a quite noteworthy and unexpected effect. The hypodermics were tried later in the case preceding trephining, as outlined elsewhere, and with good results. This is the last case of status-epilepticus which we have had here. We have tried the remedy on the mental confusion of an epileptic state with somewhat of temporary benefit, and are trying it now on various other epileptic temporary conditions that come up from time to time. Its permanent benefit must as yet be considered very doubtful.

*Massage.*—This was first introduced systematically last year. The very first case taken by the members of the class in massage, a case of "post-operative" exhaustion or shock, progressed so steadily and logically toward health that it acted as a great incentive to the class to continued work. The case was one of confusional state of mild melancholia, and the Wier-Mitchell treatment of rest, massage and electricity was very effectual.

Contagious diseases have been very rare in the hospital. During the last two years, however, we had several cases of measles and several of mumps; in all but two cases, however, among the employees. We had three cases of typhoid fever, all sent to us from the cities. We had no dysentery except in isolated cases during that period.

## CHRONIC INEBRIETY—FROM A MEDICO-LEGAL POINT OF VIEW.

Read before the American Association for the Study and Cure of Inebriety, in New York City.

BY T. D. CROTHERS, M.D.

SUPERINTENDENT WALNUT LODGE HOSPITAL, HARTFORD, CONN.

The chronic inebriate appears most frequently in the lower courts charged with crime against persons, and also minor grades of crime against property. He is commonly a continuous drinker, taking spirits daily, and to excess, when he has the means to procure it, and the conditions are favorable; or a periodic drinker with distinct drink paroxysms, at uncertain or definite free intervals. The paroxysms

subside usually from exhaustion, and begin again when a degree of restoration comes on. Such persons are more commonly laborers, mechanics, bar-keepers, boatmen, hostlers, and others of servile occupations. A certain number have descended from higher levels of business and social life, and a certain percentage are wrecks from various disasters; but the larger proportion are degenerates from inheritance, and have never been able to rise above the present levels. In appearance an irregular shaped head, face and body are often prominent. Often they are of large coarse frame, or small irregularly developed bodies, with coarse, bushy, or thin, straggling hair, irregular projections or defects of the nose, mouth or eyes. The entire body seems to be stamped with signs of imperfect development and degeneration. Such persons begin to use spirits early in life and are usually intoxicated at or before puberty.

This drink impulse is often associated with dangerous sanitary conditions, with irregular, unhealthy living, sleeping in bed-rooms insufficiently lighted and ventilated, and living on bad, innutritious food, also in a bad mental atmosphere. Add to this the continual indulgence of all the impulses and passions, in surroundings full of the contagion of bad examples, and the result is inevitable. There is here a constant widening perversion from the natural standard of mental and physical health. Exhaustion and drinking of early life is followed by degeneration, which affects the entire organism. Ambition dies out except for the most selfish gratification. Criminality grows out of these surroundings as naturally as weeds spring up in a neglected garden. The evils they suffer from perpetuate themselves, and grow more and more rank. All effort to rise to better conditions of living and acting involve the exercise of powers which are either wanting, or are feebly developed, or early crushed out by the predominance of other elements. As criminals they always lack the boldness of experts; usually they are followers acting under the guidance of others, and are sneak thieves, petty swindlers, gamblers—ready to engage in any scheme that will furnish sources of gratification to their passions, without much danger or special labor. As inebriates, they drink insanely for a time, governed by circumstances and conditions. Some of these cases are reared in bar-rooms and the lowest circles of life, and have the marks of pronounced degeneration. Others come from the wealthy classes, or in those inheriting large amounts of property and have grown up without any fixed purpose in life. Not unfrequently they have squandered their patrimony, and been placed in positions where all efforts to help themselves have resulted in failures. They are ordinarily marked by a weak mind and unbalanced judgment, and suffer from neurosal and mental troubles, and are filled with delusions of oppression and wrong at the hands of others. Conscious that society is at war with them and its methods antagonize the full play of their passions, they accept the situation and never seek to change or vary the conditions. Finally, they rapidly become beggars, criminal paupers, robbing their relatives and friends; also lapsing into communists, full of all the small vices, ready at any moment to aid in crime, or take advantage of any weakness, licentious and drunken at all times, and resorting to the lowest devices to gratify their impulses. Syphilis and general degeneration are common—improvidence, fawning, and

audacity are marked. In some cases they possess an apparent average or superior brain power, coupled with a defective moral force, and general want of control. They are more prominent as inebriates than as criminals, and often do criminal acts under cover of apparent drunkenness. This class are the skeletons haunting their friends continually for money and support, rarely committing noted crimes, but always in centers of low dissipation.

The second group are made up of persons who have been clerks, traveling men, peddlers, gamblers, and swindlers of all kinds. They are higher up than the last class, and possess a degree of activity which is evidence of more brain-power. Quack doctors, police, lawyers, defaulters, and patent swindlers are of this class. They frequently inherit an unbalanced organism and a distinct degenerative diathesis; with a family history of insanity, epilepsy, inebriety, syphilis, criminality, cancer and consumption.

Like the first class, they are largely the outgrowth of the surroundings, originating in bad sanitary and mental influences from early life. The worst phases of this class are seen on the frontier, as miners, speculators, and gamblers, or in business centers of large cities, as brokers, agents, and middle-men, who are ready, with any excitement or excuse, to defy law and order. As communists and railroad rioters they have attracted much attention for some time. Frequently they are filled with delusions of wealth and power, are superstitious of fate and chance, and alternate between hope and despair. Failure follows in nearly all circumstances of life, and is attributed to others, and the wrongs they suffer at their hands. While complaining bitterly of the dishonesty of others, they continue to cheat and drink in an aimless, impulsive way. They have appeared in the temperance work in great numbers, and have been noted as defaulters in coffee-house enterprises, and as lecturers recounting their experience, and soliciting help to build up again, etc. With a degree of sharpness and low cunning that is rarely obscured by drink, they have found the various temperance movements of the day a field for the fullest play of all their talents, which they are not slow to occupy. They are truthfully called the temperance tramps of the day. As inebriates they are noted for their marked periods of sobriety, and the unexpected, insane-like relapse, which seems to be partially under the control of the will. After the fullest gratification of the disordered impulses, they stop short and seem to recover. They commit crime in this impulsive, unreasoning way, confusing courts and juries as to the motive present. In asylums and in prisons they are always the most hopeful, and are sure to create sympathy, and gather about them friends which they sooner or later victimize.

In both of these groups the surroundings and predisposition to criminality and inebriety are about equally developed; sometimes one predominates over the other, and in some cases they exhibit much skill in concealing the one or the other; profound degeneration and suspension of the will and moral power is present in such cases. They never realize anything but the fullest gratification of the lower faculties as the ideal of life, and criminality and inebriety are the best means to this end. They suffer from neurosal disorders, such as exhaustion and a special degeneration of the nerve centers. Either from a non-development or a general perversion of functions

and structure, they are born both inebriates and criminals.

Such persons are usually marked in every community by their irregularities of living, and mental peculiarities, as well as physiognomy. They appear as inebriates in all grades of crime, and are seen in prisons, hospitals and work-houses, all over the world; and are frequently studied in courts of law and insane asylums, as types of all inebriates. Literally, they are all moral imbeciles, that drift up and down the world like ships without a rudder or compass.

They are committed for crime against both person and property, and constitute over 50 per cent. of all the inmates of prisons and jails. Not unfrequently they occupy places of trust in society, and when tempted fall precipitately, and puzzle experts and judges to determine between insanity and criminality, and the measure of responsibility.

The inheritance of disease is more marked in this class than others. Dr. Stevenson remarks: "There can be no question but that heredity exists in the mental as well as the physical world, and that the diminished stability of organism and perversion of physical function are transmitted with as much certainty as the germs of disease; that brain structures receive certain tendencies from inheritance, which bind it down or control its future, or that it has a certain capacity for impressions and energy of organism which goes with it always after."

This expresses clearly the doctrine of heredity which is now accepted as an established fact. The inebriety of this class is of the same order of neurosis as insanity, and depends upon some molecular change of cell and nerve tissues, which coming down from parent to child fixes the mental and physical character with certainty. In other words, it is a symptom of physical degeneration of the nerve centers, an outward expression of an inner condition of disease, always connected with degenerate undeveloped cell and nerve structures. All this is confirmed by clinical histories of numerous families where, for generations, the criminal insane and inebriate neurosis has developed in one or more of the family.

Such persons possess a distinct neurosis, which manifests itself either in inebriety, criminality, or pauperism; or, very commonly, two or more combined in one. This degeneration may not be tangible to any physical examination, but later, the autopsy and microscope often indicate distinct cell changes.

When a certificate of continuous and excessive use of spirits is ascertained, there is specific degeneration of both the brain and entire organism. If the history indicates a diseased ancestry, this degeneration is more pronounced. The direction of these defects will be toward imbecility and general paralysis. In one case a low type of conduct and reasoning will appear, and sharp reversion back to mere animal life are the prominent features. In the other, mental exaltation appears with delusions of power and capacity, beyond all ranges of reason and observation. The brain is disorganized and weakened. A progressive dissolution has begun which is apparent in the general depression and failure of all the mental activities. Such cases use spirits more uniformly, and are more stupid from a less quantity of drink and grow more incapable of work; muscular control of the body is lessened; the use of the hands and legs becomes feebler, memory fails, and ideas and

judgment are faulty. Apathy and indifference to himself and surroundings, and no thought except to procure spirits are often prominent. Excitability and irritation occur in some cases and crime follows, which is usually impulsive, unreasoning. Assaults are committed on any one, both with or without provocation and no apparent realization of the act and its consequences are noticed.

The following are some common examples: a chronic inebriate of this class stumbled and fell on the street and was helped up by a stranger who jokingly alluded to his condition. He seized a stick and killed the stranger without a word or exclamation, and continued his walk down the street all unconscious of what he had done. Another man of this class shot a stranger who looked at him closely on the street, attracted by his staggering gait and manner. In a third case an inebriate killed his wife because she did not have dinner ready when he came in. These are common examples of chronic inebriates in a stage of dementia suffering from paroxysms of irritability and delirium. The dull apathetic cases are often involved in crime against property. They are stupid thieves, coarse bungling swindlers, and commit assaults and even murder when driven to it by circumstances. Seldom any premeditation is associated with crime they commit, and the same indifference is manifested as to the consequence of their acts.

When these demented cases develop symptoms of general paralysis, most commonly noted by mental exaltation and mild deliriums of strength and power, crimes against person are common. If against property it is from the suggestion and direction of others. Such cases become noted for their prominence in conversation and manner, and general recklessness of conduct. They drink at all times and are not often intoxicated or stupid from spirits, but are always impulsive and vociferous, never resenting insults by violence, and growing more and more egotistical. In the early stages they are politicians and reformers, and enthusiastic followers of every new movement that is revolutionary or lawless; later, they are senile egotists who boast of their influence and power. Often such persons are bigamists, and accessories to criminal acts, assisting and concealing crime and criminals. While such crime may show reason and cunning it will always lack in consistency and uniformity of conduct, and be noted by blunders and bad judgment in all their acts. The secretiveness of one stage of the criminal act, will break away into the most transparent expression of his purposes and motives in another. His denial of acts and explanations of suspicious conduct will be thoroughly imbecile and childish, and convey the real truth more accurately than confession of any kind. Statements of crime, either as witnesses or participants are of no value unless confirmed by other testimony. Some of these chronic inebriates manifest an unusual susceptibility to the personal influence of others. Particularly to some favorite bar-keeper who furnishes the spirits, or some woman along the same line of living, and but rarely for any one who antagonizes his mode of life and conduct. This is practically a hypnotic power along the lower levels, and on the plane of everyday life. But it varies widely in uncertainty and brevity. The hypnotic control of a chronic inebriate is very unstable, and while it may be used for the purpose of crime, can not be de-

pended on to conceal it. To make a man intoxicated and suggest crime to him is not unfrequent, but the commission of the act depends on a wide range of circumstances that may vary any moment; circumstances that the operator has no control over, and conditions that must be in harmony or the act will fail.

A saloon man sent an inebriate to set fire to the home of a temperance reformer. The flask of spirits to give courage for the act brought on a stupor, and after a short sleep, and confusion of mind he built a fire in the barn of the saloon-keeper by mistake. In another case an inebriate was urged to kill a certain man and partially intoxicated was led out where he could commit the act. He evidently became confused and began firing at every moving object, then when his victim appeared, confessed that he came to shoot him, and after an emotional period of weeping offered to kill the man who sent him on this errand. Often the statement is made by chronic inebriates, that persons have suggested crime and offered to reward them for the commission of such acts, but why they were not committed was not clear. In reality the inebriate mental condition is so uncertain that but a limited range of criminal acts can be committed only from the most favorable circumstances, especially crime by suggestion from outside sources.

The man who is apparently under the influence of some companion, who urges him to commit a criminal act fails because of some slight obstacle at the time or some sudden change in his mental condition. Such a case may go home and kill his wife or some other person on the slightest provocation, or commit some strange crime, without suggestion and from a passing impulse. The suggestion to have committed this crime any time before would have been unheeded and failed.

In reality the chronic and degenerate inebriate, while in some cases susceptible to suggestions of criminal acts, lacks reason and steadiness of purpose to carry them out. The confused brain is the center of conflicting impressions and rapidly physiologic changes that make it impossible for any fixed line of action to be pursued. Each glass of spirits increases the circulation of the blood in the brain for a brief time, then diminishes it. The exhilaration and rapid thinking of one period is followed by the depression and slow confused thought of another, and these follow each other so rapidly that it is almost impossible to follow any special line of conduct or carry out any particular idea. In certain cases confessions of criminal suggestions are made that are false. Crime is committed and the inebriate when sober is unable to explain why he should have acted thus. The thought that possibly some one urged him to do the act occurs. After a short time this becomes a conviction which increases with each repetition.

In one instance an inebriate who had shot his brother was questioned at the station house by a zealous officer, who suggested that he committed the crime under the direction of an enemy of the murdered man. He accepted this theory and confessed to an elaborate plot, in which all the details were described minutely. On the preliminary trial this story was elaborated, and accepted as true. Later, it was proved to be false in every particular. The prisoner had not seen the man who suggested the crime for many months, and at the time he was supposed to have instigated the crime was in a distant part of the State.

In the second case an inebriate who committed an assault which proved fatal, was told by his wife that she believed it was done at the bidding of a certain companion who had great influence over him. He accepted this and asserted it to be true, giving minute details. Later, it was ascertained to be false, and without any basis of reality. The statements of chronic inebriates of the causes and conditions of crimes which they have committed, are unreliable and untrustworthy unless confirmed by other testimony.

The possibility of committing capital crime at the suggestion and bidding of other persons is always open to grave doubts and should never be accepted as a fact unless established by very clear evidence. The statements of undue influence and suggestion of crime after the act by the criminal may be equally doubtful and should require the strongest proof before acceptance. In civil contracts and wills this question of suggestion is more frequently an issue. In wills the point raised is the undue influence of some interested party exercised when the man was intoxicated. Here, as in criminal acts, there is a wide range of possibilities and no general or uniform line of conduct which can be predicated. The enfeebled brain alternately exalted and depressed, always under a mask, and never able to appreciate its relations to the surroundings will act differently at different times. In one case such a man willed his property to his youngest son, and the next day to a daughter, then to the physician. In each case he declared he had no other wills and was, no doubt, honest in his convictions. It is extremely doubtful if any acts or disposition of property can be relied upon as rational, unless the act in itself is consistent and reasonable and just in its results to all concerned. A chronic inebriate disposed of a large property to many persons, and an issue was raised of his intoxication at the time of making the will. It was proved that the provisions of the will had been determined and mentioned to many persons long before, and in reality was simply the culmination of previous reason and judgment, that could not have been influenced by the intoxication at the time of signing the will.

The chronic inebriate not infrequently exhibits new and distinct personalities of thought and conduct. When drinking rapidly he may display emotional delirium of thought and conduct. At another time when using spirits regularly in excessive quantities, be very still and reserved, and show caution in conduct and speech. In the first period he may be loud and violent in his language but excessively cowardly, and the possibility of committing a capital crime at this time is very slight. In the second period the crime may be the sudden impulse of the moment, and never premeditated a moment in advance. In some persons, delusions of persecution, open or concealed, may be present and crime may follow as a sequence to this, but only from a rare combination of events. In other cases optical and aural delusions are the basic exciting causes. In some cases where after long continued intoxication voices are heard, some of which are threatening and insulting, sudden assaults are committed, the real causes of which may be forgotten. In a case of this kind a fatal assault was committed which was explained as self-defense at the time. The next day all recollection of this had faded away. In a second

case a fatal assault of a stranger on the street was explained by the criminal inebriate as self-defense. The victim came toward him with the most violent language and threats, telling him that he had a concealed knife which he would use and send him to hades. In the wild frenzy of fear the act was committed. The victim was quietly walking down the street, all unconscious when struck down. The criminal could not recall the reasons for this act a few hours later.

Optical delusions have been noted in some cases where suddenly the appearance of some man on the street would be interpreted as evidence of assault, and in defense the inebriate would attack him. Such cases are termed mistaken identity, and are settled as blunders and accidents. Some chronic inebriate will suddenly on the street have optical delusions, and conceive that the man who is passing him with his hand raised, is in the act of assaulting him, which he repels instantly, only to discover his mistake which he explains as mistaken identity. He may at this moment hear voices and have aural delusions as well as optical delusions; after the act he will have no clear recollection of what has occurred. *Many of the criminal acts of this class come from centers of infection, such as a dog fight, a personal altercation, an accident, some apparent wrong, or injustice; railroad and other strikes, or any occasion in which intense excitement is developed seem to have a powerful influence over the alcoholized brain. Crime under these circumstance is fitful, unreasoning and largely accidental, and of an insane transitory type. Property is destroyed, assaults are committed and strange unaccountable wrongs are enacted, associated with a degree of frenzy that dies away quickly before any superior force.*

The chronic inebriate thrown into centers of excitement, drinks freely and is soon narcotized and unfit for any physical or mental activity. On recovery from the stupor in centers of similar excitement, he becomes more delirious, and the former delusions are more prominent and new ones added.

Practical observation shows that the open saloon near centers of great public excitement is not only dangerous but increases the services of lawlessness and incapacity of all who frequent it, to act rationally. Crime committed in such circumstances and surroundings is practically insanity.

Sexual crimes by this class will be of the same impulsive unreasoning character. The history of the case, and circumstances of the act, will rarely fail to show the delusional and delirious character of the mental operations. The sexual impulse in these cases is usually exhausted early in the progress of the case, and passion is a small element in criminal acts. Cases who have been excessively immoral, as a rule, have parietic symptoms and are always exhausted and have incipient or pronounced states of dementia. Criminal acts lack in reason and premeditation, also ordinary caution and prudence, and when studied point out clearly the degenerate brain of the person. Any criminal with a history of chronic inebriety, meaning continuous and excessive use of spirits, is a pathologic case and should come under medical care and study at once, before his case is adjudicated or is examined legally. What are the physical conditions which have entered into the act, and been influential or prominent as causes? It is the answer to this question which will determine what disposition should be made of the criminal.

## READY-MADE MEDICINES.

BY CHAS. E. WARREN, M.D.

ROSLINDALE, MASS.

Some of the many medical journals, and societies, assuming a censorship in the matter, unauthorized by reason, and mistaking a spirit of obstructiveness for one of conservatism, have been trying in the past and are attempting at present to pronounce a wholesale damnation of ready-made medicines, without discrimination, asserting that such preparations are unscientific and unreliable; branding the physician who avails himself of them as too lazy to write a prescription, or too ignorant to know how. The physicians are also stigmatized as violators of the Code and irregulars, and are tacitly excommunicated from the body medical, by these self-appointed and self-righteous judges. It is too true, 'tis a pity too, that there are in existence many medicines, made up of unknown or unheard of ingredients, claiming to cure every ill that flesh is heir to, and many besides that have a spiritual existence only in the mind of the originator; myths, which he sends forth to dwell in the bodies and terrify the minds of his victims, as spooks and ghouls were supposed to do in ancient times, living on human flesh and preying on immortal souls. Of such remedies we can not express too deep an execration or pronounce too severe condemnation. We trust that there are few physicians who are so low in morality or so poor in purse as to resort to the use or recommendation of such remedies, and we are sure that all physicians and well-educated people will agree with us that the use of patent medicines without a knowledge of their composition, does injury to the health of the people.

"Because they may, and in fact sometimes do, contain powerful or poisonous articles unsuspected.

"Because they always may be, and often are inert, and become a false reliance to the neglect of other and due measures in the care of health.

"Because they are liable to be changed in composition so that any experience of their effects as they are purchased at one time, is not conclusive as to the same-named articles purchased at another time.

"Because they favor excessive recourse to medication, and thereby increase the resort to physicians, and intensify the demand for the physician to give medicine whether needed or not.

"Because it is submitting disease to the treatment of a distant and irresponsible stranger, and hazarding health in an apparent game of chance.

"Because they are trusted to act as an antidote in the sense in which no medicine can act.

"Because their analyses show the greater part of them to be given with multiplied falsehood, and the patronage of falsehood must be demoralizing both to the mind and to the body."

On the other hand, there is a class of special medicines, the composition of which is known, many of them prepared from the formulas of reputable and eminent physicians of high standing, by large houses or competent individuals, who have attained great skill by long experience. Such preparations have a merited place in modern medicine and are to a greater or less extent, employed in the practice of every physician.

It would be manifestly absurd to condemn in one sweeping statement, without a hearing and without qualification, all remedies known by a special name

or which are superior in purity, elegance of preparation, facility of administration or assimilation, or which are prepared by a well-known house, simply for any one of these reasons mentioned.

It is claimed that the use of these remedies is unscientific. But why, forsooth? Is it not unscientific and irrational not to use them? Medicine ought to avail itself of every remedy that it can obtain.

The Code asserts that it is unbecoming to the profession to keep secret any remedy which is found to be of benefit to mankind. But if we are required to give information to our confrères, *pro utilitate hominum* should we not also be willing for the same reason to accept information, or its equivalent, a remedy which will alleviate suffering or cure disease?

The duty of the physician morally, aside from monetary questions, is to alleviate sickness and this he is in honor bound to do, in allegiance to the name he bears, regardless of any code to the contrary. If a medicine is in the market which is superior to any that he knows of, he is bound to use it. Even the courts of justice say this, for a man is supposed to keep abreast of the times and to give his patient the benefit of all the improvements that progress may have introduced.

Many of the preparations in that classic book of reference, the Pharmacopeia are merely empirical compounds, some of them centuries old, handed down with the Code, as relics of a by-gone age, moss-covered milestones in the road of progress, which would be more fitting as tombstones of the dead past. When we read the list of advantages claimed for some of the official drugs, and see what an army of ills each one can slay single-handed, yea, more than the jawbone of the ass, in Samson's hands, we are led to think that the description is nearly as inclusive and sweeping as that of some quack medicines which claim to cure everything without regard to sex, age or nationality.

Many special medicines contain but one remedial agent in an agreeable vehicle or combination. Others are rational compounds which clinical observation and physiologic experimentation have shown to have a real value in medicine. No one can consistently deny but that the value of a given drug is increased with its elegance of administration or perfection of assimilation. A cod-liver oil emulsion is certainly tolerated in many cases where the plain oil would be rejected, and we think the physician who would refuse to use one of the many emulsions in the market in such a case would be guilty of contempt of the times and negligence of his duty to mankind. The same is true of all elegant preparations; gelatin- and sugar-coated pills, encapsuled powders, cachets, flexible capsules, elixirs, syrups and the like, and in especial of prepared foods, yet such is the obstructiveness of conservatism that at a recent State meeting of physicians all food articles were excluded from the exhibit. Such an action was certainly very short-sighted in its policy and derogatory to the good name of the profession as a progressive body. Physicians, who all of their lives have laid special stress upon the advantages of a properly regulated regimen in living and eating, and have attempted to discourage the indiscriminate employment of medicine by the profession, and the irrational resort to drugs by the laity as a cure for every ill, are helplessly and involuntarily placed in an anomalous position by such an action which seems to set medication above treat-

ment. They seem to say to the young physician, You must give medicine; let nature take care of herself. Medicine you must give! Accordingly the advance guard who depend more upon a rational treatment, are cut off from the main body of the rank and file and left without support.

We eat to live, but unfortunately some are so constituted that it is very difficult to find anything suitable to eat. In wasting diseases, in fevers, where it is all important to keep the spark of life alight until we can subdue the raging disease, or until it wearies itself out and its violence is overcome by sheer exhaustion; in such cases where each drop of nutriment is fuel, like oil for life's flame, we welcome liquid foods, beef extracts and other invalid foods as we would nectar from the gods. To the invalid, such foods may serve as a staff to aid him on life's rough road, to help him to ford the river of disease, and perhaps to gain the vantage ground of health beyond. In such a case, food is far more valuable than medicine and, in fact, in some cases medicine is injurious.

It is said that ready-made medicines are unreliable. In truth, many of these are more reliable than those extemporaneously compounded. Even the druggist who attempts to dissuade the physician from the use of these articles, avails himself of a certain class in his extemporaneous work. Tinctures, syrups, extracts, plasters and the like are sold in large quantities to the druggist, and few at the present day fill their stock bottles with their own preparations, since they can purchase them, of standard and uniform strength, cheaper and better than they can make them extemporaneously. In the preparation of these remedies the purest and freshest drugs are employed, as a rule. Expensive machinery is needed and the utmost care is taken at every step to retain the activity of the drug. Careful assays are made during the progress of manufacture and a standard article is placed on the market.

It is asserted that the use of these remedies is a violation of the Code of Ethics. It is not! These preparations are not patent or secret and are not vaunted as cure-alls. They are advertised, legitimately, in medical papers of established character, the proper medium for conveying information to the profession. The manufacturers incur great expense to inform the profession still more, by samples and circular letters, and by their agents, all of whom are as a class gentlemanly in their address and unobtrusive in their manner, contrary to the rule of the road that "a drummer is a bummer." Many of these agents are young physicians and are thoroughly entitled to the respect of the physician upon whom they call. No man knows so much but that he may know more. I am not ashamed to say that I have learned many points of value in talking with such men and have seen some very pretty and striking demonstrations in my office, and yet some men who are ethically gentlemen prove themselves practically bores by their ungentlemanly reception of agents, forgetting that civility costs little and is worth much.

Any one who uses ready-made preparations, does so understandingly; the character and quantity of the ingredients is known; the dose of each is regulated and it is as proper to prescribe them as it is any drug in medicine. It is unfortunately true that these remedies may be abused. Manufacturers may advertise their preparations among the laity and they may

thus become household remedies. But if they do good and relieve suffering they are in accordance with the Code. Then, too, there are many drugs that are household articles such as Jamaica ginger, paregoric and the like, and yet we prescribe them in spite of the fact that they are known to the public. Granting that the manufacturer abuses the confidence of the physician, the latter has the remedy in his own hands. He alone can regulate his own actions and it is manifestly unjust for any man or clique of men to lay down arbitrary rules for his guidance, to trespass upon his liberty, or to dictate arbitrarily, "this, thou shalt not do."

I am convinced that much of this hue and cry is raised by mercenary druggists, actuated by envy or malice. One reason for this is that it is becoming possible for the physician to dispense his own remedies, thus naturally depriving the druggist of a large percentage of profit. His cupidity being disappointed, he turns like a snapping dog on the one who opposes him and by blackmail attempts to injure him. In former days the physician properly filled his own prescriptions; the druggist was a latter-day convenience, but now the physician has become the druggist's convenience. The patient comes to a physician and gets a prescription, which he has charged; he takes this to the druggist who fills it and gets cash, several hundred per cent. upon the dollar, in many instances. If the druggist is not over-scrupulous, he will not hesitate to fill the prescription an indefinite number of times, by number, for any one who may call, or to recommend the prescription to others, or to put it up as a preparation of his own. We once had a patient who begged for a face lotion and we gave her a prescription making a 4 ounce mixture. She liked this so well that she had the druggist put up a gallon of it and retailed it to her neighbors and has since established a thriving business. In another case, an enterprising druggist, more enterprising than honest, criticised a prescription and the treatment, and sent the patient to another physician who paid the druggist a percentage—and the patient—died. These are not imaginary cases but facts, for which I can vouch.

Physicians can change all this and easily settle the much disputed point as to the ownership of the prescription by furnishing the patient with his medicine, no prescription being needed. The patient is thus better satisfied as he gets something material, a *quid pro quo* for which we will pay much more readily than for a prescription and advice. The average mind can not approximate or appraise the value of an opinion; it can set a price on the material substance. Hence it happens that the druggist is paid, while the physician may whistle for his fees. The one is a business transaction, by a tradesman, the other an ethical courtesy extended by a professional gentleman, who sets a false dignity upon himself, and his comrades, and who is deterred from setting a just money value upon his services, because forsooth it is derogatory to the dignity of the profession. Still a man is thought more of if he insists upon his rights and for value given a physician certainly ought to insist upon an equivalent value in return.

Aside from the politic aspect, the physician can often alleviate suffering, at once, by having a medicine case handy, greatly to the relief of his patient and to his own reputation. Tablets, triturations, and

concentrated tinctures and extracts furnish potent remedies, in a portable form, which are of especial value in emergencies and in night service when it would be impossible, or would involve great delay to obtain them from a druggist at a time when a minute saved may mean a life saved. The charges made are serious and demand earnest consideration, but they should be conscientiously disposed of and be handled without prejudice. We have spoken of the Code. We do not want to be considered as opposing the Code. It is very good what there is of it, and plenty of it, such as it is. It contains incongruities, inconsistencies and contradictions which are not acceptable to a reasoning man. It attempts above all to manufacture a gentleman by arbitrary rules, and yet all know that gentlemen are born so and are not made so. The profession, individually, need no such Code. If a man can not keep the Golden Rule and the eleventh commandment, on principle, he ought to do so from policy. The profession do need a rational code of instruction in complicated cases and need it very much. The present Code is antiquated, and in many respects obsolete, and to be guided by it is like navigating one of our monster iron steamships with a crude and ancient compass and a roughly drafted primitive chart, both uncorrected and uncertified and sure to run the ship to destruction.

The Code tries to cover too much and takes too lofty ground. Some consider medicine a science, others an art. Some think physics a profession, others a trade. No rules can cover all this variety of purposes. The business must be governed by business laws which are practical. Science, which is essentially built upon theory, until proved by fact, can not be bound by narrow rules but must have latitude to soar and be visionary, to dream and, perhaps waking, find a reality.

All of us, as physicians, I am sure honor the first principle of our profession, that to alleviate suffering is of the first importance. I am sure we all realize the high morality of our calling and endeavor to advance its highest good, but incidentally the corporal existence must be maintained, for without a body there is no mind. So the money question is an important one after all. Way down at the bottom of the matter, at the root of the evil, we catch a glitter of gold, and we see the whole of mankind digging for that glittering gold with all their energy. Fame is but a name and glory but a story; both may make a good dessert but not a good square meal and neither has a marketable value.

### GANGRENOUS INGUINAL HERNIA.

HERNIOTOMY INCISION MADE—BROKEN GUT FOUND—  
LATERAL INTESTINAL ANASTOMOSIS WITH MURPHY BUTTON THROUGH INDEPENDENT LATERAL ABDOMINAL INCISION—SIX MONTHS LATER, AN END-TO-END UNION FOR THE CURE OF FECAL FISTULA—RECOVERY.

Read before the Chicago Pathological Society, Feb. 11, 1895.

BY THOMAS A. DAVIS, M.D.

CHICAGO.

Patient a male, white, aged 36. Admitted to the Medical Department of Cook County Hospital on Feb. 27, 1894. At the time, the following brief his-

tory was written: patient has been sick about one week, suffering from severe pain across the lower part of abdomen. His bowels have not moved for five days. He has suffered from a right inguinal hernia for nineteen years and stopped wearing a truss two weeks ago because of pain in the abdomen which he thought due to the truss, which had been worn with comfort for years previously. Has been vomiting for three days (not fecal) and has also had troublesome hiccoughs.

Examination: chest negative; abdomen rather distended, tympanitic on the left, flat on the right. Hernia is reduced. No impulse on coughing. Patient thinks that the hernia does not come down, when he stands up and coughs.

Morphiæ sulph. . . . .	gr. 1-6
Pepsinæ . . . . .	gr. ii
Sodii bicarb . . . . .	gr. iv.
Bismuth sub nit . . . . .	gr. v
Pulv. Rhei . . . . .	gr. ii

Hot fomentations to abdomen.

This was the treatment given from the day of entrance into the hospital February 27, until March 3, when I made an examination of the case with the interne, and concurred in his diagnosis of strangulated hernia. The patient was immediately transferred to my care in the surgical ward and prepared for operation. The diagnosis was based on the history gotten at the time of the examination: that the intestinal obstruction symptoms did not subside after the apparent reduction of the hernia was made; there was tumefaction and tenderness on palpation in the right inguinal region (the seat of the hernia); the temperature was 97 degrees F., with pulse 84 and respirations 24 per minute. The patient's features were expressive of great distress.

Operation: an incision as for herniotomy was made. The hernial sac was found to be gangrenous, the gut gangrenous and broken open and fecal extravasation, which had given rise to a phlegmonous inflammation of the surrounding tissues had occurred. This seemed to me to be a very unfavorable field for a hernia-laparotomy and equally so for the establishment of an artificial anus, as very little, if any, intestinal contents passed during my inspection of the broken-down gut; and if, as I thought, the obstruction was due to inflammatory adhesions, together with still existing primary constriction at the inner ring, to break these adhesions down, it seemed to me, would invite a septic peritonitis. For these reasons I concluded to make a lateral-intestinal anastomosis with the Murphy button through an independent lateral abdominal incision. The abdominal wall was thoroughly cleansed and the herniotomy wound was packed with iodoform gauze. A lateral (right) abdominal incision about five inches in length was made, extending to within two inches of the upper end of the primary herniotomy incision. When the parietal peritoneum was cut through, a distended, congested, intestinal coil appeared and was traced but a short distance downward when its attachment to the internal ring was found. This was the proximal gut. A loop of collapsed intestine was drawn up from beneath the distended gut, traced to the same point of adhesion, and was considered to be the distal gut. There was no evidence of peritonitis. A lateral anastomosis was quickly made with button No. 3, and the abdominal wound closed. Free fecal circulation was promptly established and patient made an uneventful recovery, so far as general health

was concerned. Locally, however, the conditions were not so favorable. The button passed down the proximal portion of the gut and necessitated extraction nearly two months later.

About one month from the time of the removal of the button, fecal discharges ceased from the fistula. Patient was now allowed to get out of bed and to be about the ward. He grew strong, increased in flesh and felt pretty well, but the fistulous discharge increased and became fecal, and patient was transferred to the suppuration ward and given a bed, the first one from the large outside door where he said he took a violent cold the first night that he spent in the ward. From this time he began to fail. A severe cough with free purulent expectoration, loss of appetite and progressive emaciation attending. The offensiveness of the rapidly soaked dressings made life miserable and the patient urged an operation for the cure of the fecal fistula. This I did on September 10.

After curetting the fistulous tract, carefully disinfecting the field of operation and packing end of proximal gut with iodoform gauze, a hernia-laparotomy incision was made, opening into the peritoneal cavity just above the internal ring. The adhesions to this gut were but a line in thickness, though quite firm and strong. They were severed with the scissors, the intestine drawn down and Murphy's intestinal clamps applied. The mesentery was then tied off for two inches from either end and end-to-end approximation, with round button No. 3 was made. The peritoneal cavity was closed by suture and the external wound was sutured, leaving small space for iodoform gauze drain.

The recovery from operation was apparently without incident, excepting that the severe cough caused some intra-abdominal pain and necessitated an extra compress over the field of operation. Button was passed per rectum the tenth day. The subsequent history is that of progressive emaciation, severe cough, profuse expectoration until death October 23, forty-three days from the last operation.

The patient was able to be out of bed for a few days from about twenty days after operation. The history of the case from the time of transfer from medical ward March 3 to the time of death could not be found, so that I have been obliged to draw almost wholly upon my memory for this description.

#### NECROPSY.

Body quite emaciated. Circulatory organs: pericardium smooth and shiny and contains about 30 cc. straw-colored fluid. Heart: about the size of owner's fist, soft and flabby, weighs 320 grams; decolorized clot in right ventricle; both ventricles contain clotted blood; tricuspid valves negative; numerous small plaques in aorta; all valves competent to water test. Pleura: adhesions on right side anteriorly; none laterally or posteriorly; few adhesions over left side; there were firm adhesions below to diaphragm. Lungs: weight together 1700 grams (left 920 grams); right lung, firm inter-lobular adhesions, crepitates and floats; lower lobe, posteriorly is firm; both upper lobes emphysematous along anterior margins; a thin frothy fluid expressed from lower lobe (edematous); small cavity in apex of this; (right lower lobe not described). Left lung: lower part sinks, upper lobe emphysematous; inter-lobular adhesions; pleura much thickened in places;

the whole lower (left) lobe has many cavities, filled with brownish purulent fluid, some of it being thick and cheesy, gray and very offensive. No description given of condition of lung around these cavities.

Peritoneum: smooth and shiny except over region of operation. Stomach: negative. Small intestines: a band of adhesions from the parietal wall near the seat of wound of operation, passed downward and attached to ilium about three feet above ileo-cecal valve. Large intestine: negative. Liver: two thousand grammes; surface smooth; markings distinct; substance firm; lobules indistinct; center depressed and periphery raised; on cut section, pale in color. Gall bladder: thirty cc., dark bile; duct patent. Spleen: weighs 140 grams; flabby; capsule smooth; section, soft and pale in color. Kidneys: embedded in mass of fat, together weigh 400 grams, right, pale on section; pyramids distinct; cortex to the medulla as  $2\frac{1}{2}$  to 1; capsule peels readily; stellate veins marked; vessels in cortex well marked; glomeruli quite distinct. Left kidney: small cyst on posterior inferior extremity; otherwise same as right kidney. All other organs examined, negative. Microscopic, anatomic or bacteriologic examination not made.

#### Post-mortem diagnosis:

1. Beginning endarteritis deformans of aorta.
2. Localized adhesive pleuritis.
3. Right lung: edema of lower lobe and small cavity.
4. Left lung: multiple cavities in lower lobe. (abscesses).
5. Parenchymatous degeneration of liver.
6. Parenchymatous degeneration of spleen.

The specimen of intestine which I will exhibit shows perfect union in both lateral and end-to-end approximations of bowel. The cicatrices are linear and slightly less thick than the normal bowel wall. The thickening near the end-to-end approximation is due to the puckered four inches of mesentery which was tied off from the intestine resected. The lumen of the end-to-end union is as large as the button; that of the lateral about one-fifth larger.

#### CONCLUSION.

1. That the cause of death was independent of surgical operations.
2. That while the statistics so recent, and as yet showing so few cases of intestinal union with the Murphy button, do not place it beyond the pale of a device on trial, yet, if the statistics are referred to at all, we have the same right to make comparison between the different methods of the application of the button. In the *Clinical Review*, February, 1895, Dr. Murphy reports, in total number of cases up to date, seven cases of lateral anastomosis for benign obstruction with seven recoveries. With my case it would be eight cases with eight recoveries. In the same report he gives, "of the resections for gangrenous hernia, twelve cases with two deaths, a mortality of  $16\frac{2}{3}$  per cent."

In both of the fatal cases the gangrenous gut was broken, and in one an extensive peritoneal infection had occurred prior to the operation.

In his conclusions, in Dictum No. 6, Dr. Murphy states that end-to-end union should always be performed in gangrenous hernia. For the reasons given, and in consideration of experience in my case, I would beg to differ, and would offer a classification of gangrenous hernia: 1, with unbroken gut which

should be treated by end-to-end union; and 2, broken gut which should be treated by lateral anastomosis.

3. That the restoration of the fecal circulation by means of the Murphy button gives a large union-lumen, with marginal linear cicatrix, and all of the apparent conditions would seem to insure permanency and adequate patency.

#### DISCUSSION.

DR. J. B. MURPHY—The question raised by Dr. Davis as to whether the lateral or end-to-end operation should be preferred is certainly one that has two sides to the question, and I can see that there is good ground for taking the position the Doctor has taken. In my most recent case, which was somewhat similar to the one reported, there was gangrene of this portion of the bowel as well as the sac; that is, the sac of the congenital hydrocele was entirely gangrenous and infected, and it has been my belief since, that if I had

merely drained the hydrocele sac and made a lateral approximation in the hernia above, I might have saved the patient. Still there was a large quantity of fluid and blood in the peritoneal cavity at the time of the operation, and the case had gone on for six days with complete obstruction. Lateral approximation could have been made very readily without opening the sac of the hydrocele. The diagnosis of the pathologic condition was not made until I opened the original hernial sac. There were two sacs in this case; one hernial, and the other a hydrocele sac, and the patient had a Littre hernia in the ring of the hydrocele sac, involving four-fifths of the circumference of the bowel. The Doctor reduced hernia from the hernial sac and supposed he had completely done so, but examination of the patient before operation showed that he evidently had continued obstruction. I believed that it was because the hernia had been reduced *en masse*, and that the strangulation continued at the neck of the sac within, as we frequently find in umbilical hernia, but that was not the case. It was simply a strangulated Littre hernia that had existed from the beginning in the hydrocele sac, as shown in the illustration.

The operation of lateral approximation frequently requires a secondary operation, but not always. Dr. Joseph Price, of Philadelphia, has operated in one case which did not require a second operation, and there are two or three others who have done the same. Another objection to lateral approximation with this method is that the button might appear on the proximal side, that is, instead of falling into the distal portion of the intestine, it will fall into the proximal portion, the distal portion having been contracted before obstruction; but if the precaution be taken on the third or fourth day after the operation, to compress the fistula so as not to permit the escape of the contents of the intestinal canal through, the current will pass out through the opening in the side of the button, and the button will not appear in the fistula but pass on into the intestine. I saw an article recently in the *Annals of Surgery*, reporting a case of this kind, in which the doctor stated that on removing the button through the fistula, he tore the adhesions that had formed at the site of approximation. The report differs very materially from one which I received from the interne who made the autopsy after the death of the patient. The interne told me that the intestine was torn loose from the abdominal wall in extracting the button, and not at the seat of approximation. The doctor who reported the case must have misunderstood the post-mortem report which he had received or had forgotten it. It makes a very great difference in these cases, for it is an unsurgical procedure to extract a button of the size of No. 3 through a fistulous opening in the intestine. Dr. Davis tells us that at the second operation there was but slight adhesion; that the adhesion of the bowel to the abdominal wall was not firm. When we are resorting to lateral approximation, one of the precautions to be taken is not to make much traction on the intestine. If this is done we will tear it loose from the abdominal wall and leakage will occur.

Another difficulty encountered in lateral approximation is that we can not always tell when we have the right coil. (Dr. Murphy demonstrated the importance of this point by illustrations.) With reference to the mortality following end-to-end approximation for strangulated hernia, where we have a gangrenous condition and all the tissues are infected, we must expect it to be large. If we have a hernia that has existed for a long time with all the tissues infiltrated, I think the position taken by the Doctor, of resorting to lateral approximation is the proper one; but if we have the gangrenous non-perforative condition, mentioned by the Doctor, I believe the end-to-end operation is preferable.

## NEPHRECTOMY FOR TUBERCULAR AND SURGICAL KIDNEYS.

Read before the Chicago Pathological Society, Feb. 11, 1895.

BY J. B. MURPHY, M.D.

CHICAGO.

The following is a clinical history of the cases from which I secured the kidneys I here present for your examination:

Case 1.—Mrs. P., age 32, of Dixon, Ill., came under my observation May, 1888. Had complained for the last three months of pressure and pain on the right side just below the margin of the ribs. The pain was of a somewhat intermittent character, at times severe and at times entirely absent, but a sense of increasing pressure on the right side caused the patient to consult a physician. Examination of heart and lungs negative, patient emaciated, abdominal walls drawn in. On the right side a movable tumor the size of a man's fist could be detected at the position of the right kidney. It was somewhat irregular and very sensitive to pressure. It moved up and down about one inch with respiration. The fingers could not be pressed in above its margin, between it and the liver. The urine showed pus in considerable quantity, a few blood corpuscles, and no renal epithelium; specific gravity 1018; quantity in twenty-four hours, forty-one ounces. The lower end of the left kidney could be felt between the hands, was not enlarged and was slightly movable. The pressure on

the side continued during the succeeding week. Urination became more frequent and slightly painful. Temperature in the evening 101, on an average. There was at all times an absence of a history of renal colic. Diagnosis: pyelonephritis. Operation, September 1888, lumbar incision; pelvis exposed, kidney opened and drained; contained pus, but no stone. I could not succeed in passing a catheter down the ureter. Pus disappeared from the urine for a time, and the patient improved. The tumor diminished in size. After a time the drainage was dispensed with, but the patient was attacked with chills and fever, and the drain had to be re-inserted. Notwithstanding the thorough drainage, every three or four weeks the patient would have an attack of fever. During the attack she emaciated rapidly, and the pus in the urine increased in quantity. The discharge through the tube was offensive. She wore an elastic urinal over the tube. About half a pint accumulated in twenty-four hours, consisting of pus and urine. This was kept up until October, 1894, six years, when the patient finally consented to have the kidney removed. Quantity of urine passed daily, through the bladder before operation, thirty-two ounces, containing considerable pus; urination every hour, day and night. The patient had a chill the second day before operation; temperature 105, pulse 134. She had become addicted to morphin. Operation Oct. 19, 1894. A posterior incision around the sinus was made, and liberation of the urinary fistula down to the perirenal adipose tissue effected; then an anterior incision along the right linea semilunaris into the peritoneal cavity. Cecum and colon were then displaced to the right. An incision five inches long in the posterior peritoneum exposed a large indurated mass extending from the lower margin of the liver to the brim of the pelvis, and from the median line to the spinous process of the ilium. The posterior peritoneum was peeled off, drawn forward and sutured to the anterior peritoneal layer, thus shutting off the peritoneal cavity from the field of operation. The process of enucleation was then begun, first on the outer side until the fistula was reached and the adhesion separated, then the upper margin separating it from the liver and gall bladder. Great difficulty was experienced in removing it from the iliac vessels. The tumor was then drawn forward in the wound, the ureter separated and cut off. The induration continued beyond, and embraced the abdominal aorta and vena cava. Twice I had my finger around them, believing they were adhesions. A very careful dissection was then made between the margin of the kidney and the vessels on the right side; the renal vessels secured and ligated; remaining adhesions separated and the kidney taken out. The ureter was fastened in the lower angle of the wound; the upper angle was packed with gauze, and a small anterior drain of gauze close to the ureter. Gauze drains were used, and the ends retained in the wound.

It was the most difficult operation I had ever performed; and I am confident if I had endeavored to remove the kidney through the posterior incision, I should have torn either the iliac or abdominal vessels or both.

The patient's convalescence was uneventful. The morphin was cut off at once, and on the third day the patient jumped out of bed and quarreled with the nurse for morphin. Still it had no untoward effect on her. The pus has entirely disappeared from

the urine. The average daily quantity is forty-seven ounces. At the time of operation patient weighed 91 pounds; she weighs now 128 pounds.

Pathologic condition of kidney: the cortex had almost entirely disappeared; here and there a small nodule of secretory tissue remained. The mass looked like a thick-walled multilocular cyst; some of the pockets had only small openings accounting for the retention symptoms. The ureter was pervious, but its mucosa very much thickened. The microscopic appearances will be described by Dr. LeCount. The gross appearances were those of a pyelitis with retention.

*Case 2.*—Mrs. C. applied to me for treatment June, 1894. She had previously suffered from a pleuritis with effusion, which had disappeared; had enlarged glands of the neck, and a family history of tuberculosis. Complained of frequent urination followed by severe pain; quantity of urine passed in twenty-four hours, thirty-four ounces. It contained blood, pus, and tubercle bacilli. An enlarged, slightly movable nodular kidney could be felt on the right side. Examination of bladder, Kelly method, showed a tubercular ulcer around the right ureter and induration of ureter also present. Urine from that ureter contained a large quantity of pus; urine from left ureter normal. Diagnosis: tuberculosis of the right kidney and ureter, with tubercular ulcer of the bladder. Patient was suffering so intensely that it was decided to remove the right kidney and ureter. This was done with an incision similar to former case, in the right linea semilunaris. The kidney was much enlarged, sacculated, still readily enucleated; vessel ligated, ligatures cut short. The ureter was much thickened and removed to below the margin of the pelvis, was ligated, and a strand of gauze brought from the ureter out of the lower angle of the wound; wound closed with posterior and anterior gauze drain; forty-eight hours drainage; removed, with result of complete primary union. Patient's bladder symptoms subsided, a very small quantity of pus being found in the urine; she left the hospital three weeks after the operation. Two weeks after leaving the hospital the tenesmus set in anew. The pus increased in the urine; the bladder symptoms increased rapidly in severity until complete control of the sphincter was lost. The position in the wound where the ureter was sewed, reopened. Bacilli were present in the urine. The patient's condition became worse. She died Jan. 10, 1895, with symptoms of uremia, dropsy, and tuberculosis of bladder.

Pathologic condition of kidney: kidney reduced to a tubercular sac; all resemblance to a kidney gone; made very fine sections. The cortex was reduced to a granulation tissue sac, caseous inside. Here and there, evidences of tubules with regenerated lining cells, only obliterated glomeruli, the so-called fibroid glomeruli on the outer portion seen. The ureter was not so much attacked by the tubercular process. The muscular walls were in fair condition. The lining was gone and the ureter filled with caseous and necrotic debris.

The anterior incision made in these cases, I consider of very great importance, as it exposes the field of operation perfectly, and all tissues can be recognized and relations kept well in view. The only advantages which a posterior or lumbar incision has over an anterior are: 1, the peritoneum is

not opened; 2, drainage. The method I used, of suturing the posterior parietal peritoneum to the anterior, before extirpating the kidney, practically closes the peritoneum and makes the operation extra-peritoneal. I believe there is very little more, if any, danger with this method than by the lumbar incision. The posterior drainage is very easy to make after the operation is complete. The removal of an enlarged and adherent kidney from a fat subject through the lumbar incision is a very difficult and trying operation.

#### DISCUSSION.

DR. E. R. LE COUNT exhibited the specimens in connection with Dr. Murphy's paper, and made the following remarks: "The specimen from the first case shows the ordinary condition found in pyelonephritis, and at first I was inclined to think it was tubercular, but on examining the capsule and the trabeculae which divided off the cavities, I find it is not. The condition of the tissue is much more firm than that usually found in tubercular pyelonephritis, although on the whole, there is not a great deal of difference between the kidney in the first case and that from the second one, which is a tubercular pyelonephritis. There is this difference in the second case, that the formation of connective tissue in the capsule is not as extensive, and the connective tissue trabeculae which run down toward the pelvis are not as extensive either. Within the cavity of the pelvis we notice various sacculations, and the dilated calices are lined by well-marked necrotic membrane which is visible even at present."

#### A CASE OF BILIARY OBSTRUCTION BY A CALCULUS, WITH INTERMITTENT PYREXIA.

Read before the Chicago Pathological Society, Feb. 11, 1895.

BY ELIZA H. ROOT, M.D.

CHICAGO.

Mrs. M., aged 50, married thirteen years, the mother of five children, all healthy, the youngest being 7 years of age. She entered the Chicago Hospital for Women and Children Nov. 4, 1894. Previous history; the following history was kindly furnished by Dr. C. D. Collins: the patient was healthy before marriage, a few months after which she had her first attack of chills and fever. Some months later her first child was born, and during the following year she was quite well. Then the second attack occurred. From then on, she had repeated attacks at irregular intervals and lasting varying lengths of time. These attacks were characterized by chill, fever and sweat, followed by great prostration. Soon after the birth of her youngest child, an attack occurred after which she never wholly recovered, but has failed in health and suffered from recurrences of the group of symptoms. She was habitually constipated, the feces clay-colored. During the last three years there has been no albumin found in the urine. She was better when upon vegetable diet. There is no history of syphilis. There was not much pain until recently, when it was severe at times. Condition on entering hospital: patient was much emaciated, skin and sclerotics deeply yellow. Coughs a good deal and suffers from dyspnea. Temperature, 99.8 degrees; pulse, 100; respiration, 36. The liver was greatly enlarged, the right lobe extending to the crest of the ileum, the left lobe filling the epigastrium and extending into the left hypochondriac region.

The patient was in the hospital one week. The urine was acid; specific gravity, 1010, bile stained in color, and contained no albumin. The pulse was irregular, ranging from 80 to 120. The temperature was from 99.8 to 101 degrees F. The respiration varied from 30

to 36, and there was great dyspnea at times. Patient died comatose.

AUTOPSY BY DR. VIDA A. LATHAM.

The examination was made twenty-four hours after death, Nov. 12, 1894. The salient points were as follows: there were firm adhesions over surface of left lung, with calcareous patch on posterior surface. The heart weighed 496 grms., and showed simple hypertrophy. The pancreas and liver with pylorus end of the stomach were firmly united by adhesions, and together weighed 3,712 grams. The pancreas was very firm and showed increased connective tissue. The liver was greatly enlarged, a thick yellowish-green fluid oozing from its cut surface. Pigmentary deposit was seen in the periphery of the lobules, and there was a marked hyperplasia of Glisson's capsule, even to its finest ramifications. The gall bladder contained little fluid, and its walls were very friable. A calculus was found in the bile passage at the junction of the cystic and hepatic ducts, the latter being larger than the gall bladder. The calculus was two inches in length. It was examined chemically by Dr. J. H. Salisbury, and found to consist of cholesterolin, the soft exterior being reddish yellow in color, but containing little or no trace of iron. Crystals of bilirubin and biliverdin were present in the liver cells, capillaries and bile capillaries. The ductus communis choledochus was patent. A point of interest was a duct-like connection between the duodenum and fundus of the gall-bladder. This is evidently a point where suppuration had occurred and healing had taken place.

The kidneys together weighed 400 grms. They were both pale with indistinct cortical markings. The spleen was enlarged, weighing 432 grms., nodular and firm to the touch, and deep red in color. The stomach was small, with thickened patches along the greater curvature. There was a decided constriction of the pyloric end at the junction with the upper two-thirds of the viscus. The peritoneal cavity was filled with a clear yellowish-green fluid. There were abundant firm peritoneal adhesions.

Bacteriologic and microscopic examination: cultures from the liver gave the bacillus coli communis and pyogenic cocci. The tissues, hardened and stained in various ways, gave the following, on section under the microscope: the spleen showed the changes of chronic passive congestion; the pancreas exhibited a well-marked chronic interstitial inflammation with indistinct parenchymatous cells; the kidneys showed an arterio-sclerosis, with shrunken glomeruli; the tubular epithelium was swollen and desquamated; the capsules were thickened and there were subcortical hemorrhages. Blood cells and casts were seen in many tubules. These changes were most marked in the left kidney. In the liver were seen a commencing cirrhosis and a perihepatitis. Bands of fibrous tissue extended in from the surface. The liver cells were cloudy, swollen and fatty. Some times between distended capillaries were seen biliverdin crystals, granular material, breaking-down blood cells, some polynuclear leucocytes and bacteria, bacilli and streptococci. In places the central vein of lobules was obliterated. There was a well-marked cell infiltration and hyperplasia of the fibrous tissue. The bile ducts were atrophied, as also the portal vein and hepatic artery. The iron reaction was tried with negative results.

DISCUSSION.

DR. J. B. MURPHY.—The symptom of pyrexia in connection with lesions of the gall tracts is an exceedingly interesting one, and one concerning which we are not yet enlightened as to the exact cause of the pyrexia. We have the pyrexia occurring most frequently where a gall stone has reached the common duct, usually in the ampulla of Vater, and we have all the symptoms of an intermittent fever, with rigors every two, four or seven days, and sometimes even every fourteen days with regularity. In the cases in which post-mortem examinations have been made, it has been found that there was always an abrasion as a result of pressure of the stone, and it is my belief that on this account as well as because the ducts in this region are richly supplied with lymphatics, we have a septic manifestation developed. The temperatures occurring from impactions higher up are more rare, but not so very much so. We have cases of obstruction (from retention) to the cystic duct. In many of the cases I have operated upon for gall stones, over 50 per cent. were from obstructions in the neck of the gall bladder or cystic duct, never involving the common duct. At least 20 per cent. of these cases were accompanied by elevation of temperature. It is my belief that we either have infection or suppuration occurring in the gall bladder where we have no history that the patient has had either the presence of a stone or disease of the common duct. We know that abscesses form in the liver from impactions in the common duct; the infection in these cases must be in the duct. Where the retention is in the gall bladder alone, without infection or the presence of pus, the temperature rarely goes above 101 degrees, and where we find the presence of pus in connection with stones and cholecystitis, the temperature, even when the common duct is not involved, is as high as 103.5. I believe these are septic conditions. It is somewhat like the temperature we have from the passage of a sound into the male urethra. For a time that was considered of neurotic or nervous origin. From this condition of the common duct abscess of the liver may follow, that is, you will have multiple infarcts in the liver as a result of impaction in the common duct, which adds further to the belief that the pyrexia is of septic origin.

DR. ROOR.—The attacks of this patient continued for thirteen years at intervals, and she had these remittent and intermittent fevers. She had been under the care of other physicians who had treated her for ague; in the post-mortem there was nothing of the nature of ague shown. The peritoneum about the stomach, the liver and the upper part of the intestines were bound down with old and firm adhesions. From what I know of the case, I am inclined to agree with Dr. Murphy's idea that it was of a septic nature.

DR. GEORGE H. WEAVER.—In a case of this kind which I reported two years ago in which intermittent pyrexia had occurred in connection with gall stones in the common duct, for twenty-five years in a woman, there was noticed in her case one symptom which I have not heard spoken of or referred to elsewhere. Her bowels were constipated continuously, and if they moved freely, within a few hours she would have an attack of colic. The only way I can explain this condition is that the gall stones acted as an obstruction to the duct, the bile accumulating behind them in such a quantity that it distended the duct so that the gall stones fell back from the opening, allowing the bile to flow past into the intestines, and the bile entering the intestines in this way acted as a cathartic and caused the bowels to move. As the bile flowed from this cavity into the intestine, it allowed the walls of the dilated duct to come in contact with rough calculi, and in that way set up a spasmodic action which brought on the attack of pain. The pain was again relieved by the accumulation of fluid carrying the walls of the dilated duct away from the calculi. This was to me an extremely interesting symptom in connection with the case, and it might be that the fever which followed the attack of pain was due to the absorption of poisonous materials which were present. If the surface of the tube was freshly abraded by contracting down upon the rough calculi, this absorption would be favored.

## PRE-COLUMBIAN LEPROSY.

BY ALBERT S. ASHMEAD, M.D.

LATE FOREIGN MEDICAL DIRECTOR, TOKIO HOSPITAL, JAPAN.  
NEW YORK.

(Continued from page 754.)

Dr. Franz Boas, who has given to the study of American races more time and interest perhaps than any other man living, who has just returned from an investigation of the Indian races of British Columbia, tells me that the Tenachca and Nass River Indians, whose diet consists mainly of small fish, smelts and shell fish (this is the diet which has always been supposed by the common people, and by many doctors, to be the predisposing diet of lepers) are not leprosy, but exceedingly syphilitic. Locomotor ataxia is almost epidemic among them. Dr. Gowers, of London, and many of our own specialists assert that locomotor ataxia succeeds syphilis, and that without syphilis there is very little locomotor ataxia. This is not my opinion. My experience in Japan, during two years of hard work, made it evident to me that in that region where they have lived in close familiarity with syphilis for thirteen hundred years, there never was, and there is not any locomotor ataxia. The same gentleman says that I am probably right in stating that locomotor ataxia has no syphilitic origin; for the old people of that tribe have a great deal more of locomotor ataxia than the younger and yet are less syphilitic. Besides, other tribes in that region examined by him have not locomotor ataxia at all, and yet have more syphilitic disease than the Tenachca Indians. Nor is it my belief, and I have had a great experience of such cases, that locomotor ataxia can be considered as a sequela or attenuated form of leprosy. For the disease called locomotor ataxia does not exist in Japan. If it was an attenuated form of leprosy, it would be found there. Therefore no matter how rampant the disease may be in British Columbia to-day, there is no evidence from this fact, that leprosy existed in British Columbia in pre-Columbian days.

Whether this syphilis of British Columbia came from East Asia or not, he is unable to say. He does not know of leprosy in any American primitive race.

Dr. Wm. F. Whitney, Curator of the Warren Anatomical Museum, Harvard Medical School, in an article entitled, "Notes on the Anomalies, Injuries and Diseases of the Bones of the Native Races of North America," published in the 18th and 19th Annual Reports of the Peabody Museum of American Archaeology and Ethnology, Cambridge, 1886, mentions among the diseases various exostoses with and without eburnation, and among the hyperostoses the subjects were as a rule persons past middle life. He says, moreover, that the flattened heads of the ancient Peruvians show also a large proportion of hyperostosis.

Periostitis is manifested by a deposit of new bone of greater or less extent, along the shaft of some of the long bones, especially the tibia. (For the evidence necessary to prove that this, as well as other changes, are the results of syphilis, see *Boston Medical and Surgical Journal*, vol. cviii, p. 365). The disease known as chronic rheumatic arthritis has also left its marks in roughness and deposits on the edges of the articular surfaces and on the bodies of the vertebrae. Under the heading, "Caries," he mentions three remarkable specimens.

The first, 17,223, stone-grave mound, near Nash-

ville, Tenn., affected the spine and there resulted an extreme case of anterior angular curvature. The disease had destroyed almost the whole of the bodies of the lower cervical, or upper dorsal vertebrae, and they had become united in a firm mass. The spinal column at this point was bent forward so as almost to touch, there being but a few centimeters distance between what are taken to be the bodies of the fourth cervical and fifth dorsal vertebrae. The amount of deformity must have been very great.

In this connection it is curious to note that there are in the museum, found in the stone graves of children in Tennessee, little clay images which are faithful representations of persons affected with Potts disease, and that many of the water bottles from the stone graves of Tennessee, and from the mounds of Missouri, represent women with hunchbacks.

From the mental acuteness says Dr. Whitney, which is so often associated with this malady, it is easy to conceive that such deformed people may have been held in peculiar veneration, or there may have been some superstition in regard to their protective influence. At all events this spine furnishes the veritable proof of the existence of persons so afflicted.

The second case of caries is found in bones, 27,372, from a stone grave in Brentwood, Tennessee. The articulating surfaces of the right femur and tibia forming the knee joint, show marked erosions of the smooth hard layer of bone on which the cartilage rests. At first sight, this might be attributed to the results of weathering; but closer inspection reveals the fact that there is a marked increase in the size of the openings for the nutrient vessels for some distance from the joint on either side, and that here and there the shafts are roughened by small pieces of newly formed bone. From this the inference is justified that the destruction noted above is the result of a chronic inflammation which in no way differs from the so-called "white swelling" of the knee that is always to be found in the surgical wards of any large hospital.

In the third case, 11,891, stone grave mound, Nashville, Tenn., it is the ankle joint that is implicated. The opposing surfaces of the left tibia and astragalus are entirely honeycombed by deep depressions, separated by irregularly shaped bony trabeculae with rounded or roughened edges. In the lower part of the tibia is seen a cavity communicating with the external surface by a small canal opening through the inner malleolus. Lying free in the cavity is a piece of dead bone, too large to pass through the hole.

These cases are interesting from the fact that such processes are now supposed to be the result of a local tuberculosis, and if this existed it is fair to assume that the internal organs must have suffered also from tuberculosis, the most common seat of which is in the lungs in some form of pulmonary consumption. This assumption is verified by one of the early writers on the habits and life of the Indians, who says of them: "*C'est peut être du même principe et de ce qu'ils ont toujours l'estoma et la poitrine découverte, qu'ils contractent une espèce de phthisie, qui les menant peu à peu en conduit la plus grande partie au Tombeau et à laquelle ils n'ont pu encore trouver du remède.*" (Lafitau, vol. II, p. 360, Paris, 1724.)—Translation. (It is perhaps for the same cause and from the fact that they have always the stomach and chest uncovered that they contract a kind of phthisis which, wearing them out, little by little, brings most of them

to the grave, and for which they have not as yet been able to find a remedy.)

There remain to note a few skulls which have cicatrices pointing to more or less extensive inflammation, the cause of which is still obscure.

The skull of a female of middle life, 18,264, from a stone-grave mound on the Little Harpeth River, Tennessee, has a number of slight cicatrized depressions, more or less distinctly connecting, passing completely round the head on the line of the forehead. Their form is chiefly linear, but in one or two places they cover spots as large as a finger nail. The parietal protuberances and frontal bone show the most extensive marks, and from the latter it passes down over the bridge of the nose. The right lachrymal canal is filled by a new and symmetrical growth of bone almost occluding it.

Tuberculation of face, from Dr. Morrow's collection of photographs.

Another skull presenting somewhat similar cicatrices, is 733, from a mound in Kentucky, in the Army Medical Museum at Washington. The whole surface of the parietal, frontal and occipital bones is covered by shallow cicatrices having a firm base, and near which are minute perforations through the intact outer table into the diploë. Some of these depressions look as if they had been made by placing a finger on the softened bone, while others are slightly star-shaped or else are linear and anastomose, surrounding islands of unaffected bone.

The general and extensive changes of these two skulls can be explained best by the assumption of a

syphilitic affection. But the appearances are not quite characteristic. There is wanting the peculiar ivory-like luster to the healed spots, and the accompanying sclerosis of the bone in general.

In No. 20,180, an imperfect calvarium from Stanley Mound, St. Francis River, are a number of very slightly depressed and radiating cicatrices situated chiefly on the frontal bone. The grooves for the arteries are very deep on the inside, but the bone is not in general sclerosed.

The maxillary bones are of interest and it is a pity that the bones of the face are in such a fragmentary condition that the exact extent of the lesions can not be satisfactorily made out. In the right antrum of Highmore, the posterior wall is thickened and the superior is covered with spicular exostoses, while a large linear one reaches from near the opening across the bottom. The whole inner surface of the bone is rough, and to it the lower part of the palate bone is intimately blended. Only a narrow strip of the hard

From Dr. Morrow's collection of photographs.

palate is left and it is difficult to decide how much of the loss must be attributed to post-mortem action. But just in a line with the lachrymal canal is a rounded and roughened edge, which must have formed part of a perforation into the mouth that existed during life. A fragment of the right side of the "sella Turcica," with an attached bit of the great wing of the sphenoid and pterygoid plates shows marks of roughening similar to that on the maxilla and palate bones, as if an inflammation had extended upward from this point. The edge of the anterior nares seems more rounded and deeper than normal.

There is less remaining of the left maxilla than of the right, but the same roughness of the internal surface is seen, and this has extended forward, partially filling up the edge of the anterior nares on this side. The socket of the first molar, which lies directly beneath, has evidently been the seat of an abscess, and it is possible that this stands in a causal relation to the changes seen on the bones bounding the nasal fossæ. It would be difficult, however, to bring this into relation with the cicatrices on the forehead.

At the Army Medical Museum in Washington are the bones of the face, with the frontal bone attached, (748) from a mound in Kentucky, showing the probable effects of a large tumor. This had completely filled up the nasal fossæ and had rounded off the edges of the nasal and maxillary bones forming the boundaries of the anterior nares. The septum of the nose and turbinated bones have entirely disappeared and the ethmoidal cells were freely opened. Through the hard palate there is an oval opening extending from just behind the alveolar process through the entire length of the hard palate, leaving a narrow strip of bone on each side. The edges of this opening are rounded off similarly to those of the nose. Possibly there may have been a congenital cleft palate into the opening of which the new growth extended.

From these facts we conclude that there exist evidences of tuberculosis and syphilis in the remains of the ancient races, but no evidences of leprosy. And we further may conclude that some ancient races of America buried images, representing the diseases with which they were afflicted. We have good reasons, at any rate, to believe that the ancient Peruvians intended to represent on their *huacos* pottery, if a disease at all was represented, one which we have good reasons to believe was considered by them as aristocratic and sacred.

Dr. Emil Schmidt, in answer to my inquiries as to evidences of leprosy in Peruvian antiquities known to him, says: "As to your questions about pre-Columbian leprosy in America, I looked once more over my collection of Peruvian skulls and mummies (more than eighty specimens), but with quite negative results. I do not remember to have found any evidence of pre-Columbian leprosy in other collections examined before. We have here, in the Leipziger Museum für Völkerkunde, a valuable collection of old Peruvian pottery; unfortunately, it is packed up in the museum, being transferred in another building. A few years ago I examined this collection rather closely, and I am sure I should not have overlooked them, if there were any unmistakable indications of leprosy."

I have addressed the following inquiry to Dr. Augustus Le Plongeon: "I can not see any positive facts showing that leprosy existed on this continent before the arrival of the Spaniards, except the possibility produced by the great intercourse with Hindostan, Indo-China and Burmah, to which you seem to attach much importance, and those *huacos* potteries, on which Dr. Muniz thinks he found leprosy representations. Have you ever seen any indications on any of the works of art of Yucatan of any representations which you might consider as relating to leprosy? Have you ever seen any representation of mutilated hands or feet? Did you ever see any corpses with such mutilated hands or feet? Upon what do you base your belief in the existence of leprosy in Yucatan, before Columbus, beside the intercourse of that land with leprosy countries?"

The following is his reply: "As I have told you in my former letter, I have not investigated in my studies if a particular kind of disease existed on this western continent before the arrival of the Spaniards, but I regard it as probable, in view of the communications that certainly existed between its inhabitants and those of all other countries, that diseases existing in said countries were propagated among

them, as they are to-day. Leprosy no doubt existed, since they had a word to designate it, and their relations with Southern India were quite frequent. In my book soon to appear, "Queen Moo and the Egyptian Sphinx," you will see the nature of their relations. The ceramics of the Mayas, at least the pieces I have seen, were ornamental, of a very different character from the Peruvian; on them were never, as far as I know, represented any of nature's deformities. The Maya ethics were of a more refined nature than those of the Peruvians. No representation on them recalls any infirmity to which the human body is subject. Their paintings and sculptures portray battle scenes, domestic life, religious and other rites and ceremonies, historical events, etc.

"I repeat, I do not know that leprosy existed among the Mayas in pre-Columbian times. I suppose it did, because they had a name for it, *Naycam*, which would not happen unless they had some knowledge of the disease."

Here we see that Dr. Le Plongeon has two foundations for his assertion that leprosy existed here before the Conquest: first, the probability of its having been introduced by the various relations of the country with Southern India; then the traditional name for it, which was *Naycam*, from the word *Nay*, to eat away, or rot. As to the first, we may say, it does not hold water. New York has a thousand times more communication with all parts of the world than Yucatan had with India, and yet it is not a leprosy city. As to the second argument, Dr. Gustave Brühl has shown in his studies on pre-Columbian syphilis in America, that the Mexicans and the Mayas, and also the Quechuas and Aymaras, of Peru, had names for syphilis before the Spaniards came. He argues that diseases introduced by the Conquerors were designated by the Naturals, as a rule, by some reference to the characteristic symptom, and that therefore syphilis especially was of pre-Columbian origin, as its name was *not* so designated by the Mexicans, Mayas, Quechuas and Aymaras. Now the name *Naycam*, which means an eating away, rotting, would have to be considered as the name of a disease introduced by the Spaniards, and beside it might be applied as naturally to lupus and syphilis as to leprosy.

I addressed also a letter to Mr. Clarence B. Moore, whose archaeological work in Florida is so well known and appreciated. The following is his reply:

"My mound work has been almost entirely confined to Florida, where I have opened about one hundred and twenty-five mounds, nearly all of which I have totally demolished. My experience, then, relates only to Florida.

"I have found a considerable number of pathologic specimens during my five years of exploration. In referring to these specimens I shall exclude all cases of fracture, as I take it you are especially interested in diseased conditions of the bones.

"I have never seen any atrophy of the finger bones, such as was indicated in your photograph, but it must be remembered that in nearly all the Florida mounds the form of burial is of the bunched variety, *i. e.*, skeletal remains of bodies previously exposed until the flesh had left the bones were buried in little piles, or scattered throughout the mound. In these interments the long bones and crania figured principally. Bones of the hands and of the feet, the vertebrae, etc., are seldom met with. Nevertheless, in some of the largest mounds, burials in anatomical order were found.

"The question which principally interests archaeologists is as to the occurrence of syphilis in pre-Columbian times. Dr. Joseph Jones in his 'Antiquities of Tennessee,' published by the Smithsonian, writes at considerable length to prove the existence of this disease among the men who made the stone graves and as these sepulchres are, I think, admitted by all to be pre-Columbian, he virtually argues in favor of the existence of syphilis among the aborigines previous to the coming of the whites.

"Dr. Jones wrote some time ago, and it has been shown that the specimens from which he drew his conclusions did not show positively the ravages of syphilis, but might have presented the same appearance through changes arising from other causes.

"Dr. Hyde, *American Journal of Medical Sciences*, 1891, has treated in an interesting and sensible way

tumuli. These burials, however, are never over three feet below the surface and by careful observation as to depth all chance of basing conclusions on late burials may be excluded.

"The question of pre- and post-Columbian mounds is warmly debated by archaeologists. The Smithsonian, all of whose work is done by agents while conclusions are drawn at desks one thousand miles away, believes in the existence of many post-Columbian mounds of importance. On the other hand all independent field-workers, such as Professor Putnam, Cushing, Moorehead, Fowke, Thurston, of Tennessee, and, in an humble way, myself, have yet to find any thing in a mound of importance, much below the surface, which in any way indicates contact with the whites. I am not speaking now of Florida, but of the entire country. Articles distinctly European are glass, glazed earthenware, iron, lead, pewter, brass, bronze, etc., etc. The Smithsonian has maintained that the copper of the mounds must be largely European and the mounds consequently of a late date. A recent writer, however, has pointed out that it is

Huaco pottery, evidently an amputated foot. Wine or water bottle, exhumed with Peruvian mummy, said to be pre-Columbian. Bandelier collection, American Museum of Natural History.

Mutilated foot of leper, two toes remaining. From Dr. Morrow's collection of photographs of leprosy deformations.

the occurrence of this blood disorder, under the heading, (I think) 'Pre-Columbian Syphilis.' Dr. Hyde arrives at the conclusion, as I remember the paper, that it would be absolutely necessary to show they were unmistakably syphilitic bones encountered in the mounds, that these mounds were of unquestionably pre-Columbian origin. To this I might add (I do not recall whether Dr. Hyde refers to it) that in mounds of great age are often found intrusive, or secondary burials. Within the past week I have exhumed a body with remnants of clothing and feathers belonging to a pillow. Later Indians, as for instance the Seminoles, who were doubtless infected, may have been buried in mounds, while to my knowledge negroes and whites have been buried in ancient

untenable to suppose that aborigines having intercourse with Europeans and obtaining copper from them should bury this copper, with a great variety of objects all distinctly aboriginal, and has, moreover, by a cloud of analyses shown that the copper of the mounds is pure native metallic copper, to which the aborigines had access and which is highly malleable and that this mound copper has nothing in common with the products of the imperfect smelting processes of the highly arsenical European sulphides, used during the fifteenth, sixteenth and seventeenth centuries.

"In Florida, in mounds of considerable size, a number of feet below the surface, beneath undisturbed strata, associated with objects of aboriginal art only, I have found a considerable number of long bones which had suffered from periostitis and osteitis of both the rarefying and condensing forms, as shown by general enlargement of the bone with irregularities of the surface, local nodular swellings, roughening

and spiculation of the surface, etc. None of these bones have been submitted to thorough examination by experts, and it is therefore impossible to say positively whether any show the marks of venereal trouble.

"At the present time, both archæologists and physicians are inclined to attach little credence to the existence of pre-Columbian syphilis.

"Most of my specimens are at the Academy of Natural Sciences, 19th and Race Streets, Philadelphia, where Dr. Dixon, the Curator, would doubtless be happy to have you examine them. I have written at considerable length as I have always maintained that the opinion of any one is valueless unless it is based upon substantial facts."

Dr Prince A. Morrow, ex President of the American Dermatological Association, who examined personally and very carefully the lepers of Molokai, Sandwich Islands, and who is, I believe, the highest authority on leprosy in this country, does not remember seeing a leper who had lost his upper lip, nor does he think that such a loss is a leprosy manifestation. He thinks, as I do, that if the authors of those *huacos* potteries had intended to represent leprous phenomena, we should find in their work mutilated fingers and toes. In the American Museum there is a *huacos* pot<sup>1</sup>, a wine bottle in the shape of a naturally sized foot, with circular flap removed from the top of the bottle, the bone representing the top of the bottle. The foot is represented swollen, with toes placed on the end in a peculiar way, but with nails showing naturally. Evidently some disease is meant which required amputation. Dr. Morrow kindly allows me the use of one of his photographs that of a leper foot (not requiring amputation, however). You will find side by side here the photographs of the bottle and that of Dr. Morrow, the latter belonging to a Sandwich Island leper. The only difference is, as will be seen, the presence of every toe on the bottle, while the photographed leper foot shows but two toes remaining. This lack of mutilation and the amputation show to me that it was not leprosy which the potter wanted to represent.

(To be continued.)

## SOCIETY PROCEEDINGS.

### American Electro-Therapeutic Association.

Fourth Annual Meeting held in New York Academy of Medicine,  
New York, Sept. 25, 26, and 27, 1894.

WILLIAM J. HERDMAN, M.D., President.

(Continued from page 726.)

#### DR. ROBERT NEWMAN, of New York, read a paper on SUPPLEMENTARY REPORT ON THE SUCCESS OF ELECTROLYSIS IN THE TREATMENT OF URETHRAL STRICTURES.

Up to date, electrolysis in the treatment of urethral strictures has been successful in the same manner as practiced by me for over a quarter of a century and reported last in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, April 15, 1893.

Therefore, I have nothing to retract but only to confirm former statements. In addition, I published in the *Times and Register*, Jan. 21, 1893, the statistics of one hundred successful cases treated by Dr. F. S. Crossfield, of Hartford, who wrote the following: "I have practiced electrolysis for the treatment of stricture of the urethra upward of eight years with success. My synopsis of one hundred cases and obser-

vations coincides with the published statistics of Dr. Robert Newman, of New York. My cases were all seen in private practice. Those reported were not selected cases, but taken in order of occurrence . . . taking the cases as a whole, together with those of Dr. Newman, it establishes the practical value of the method."

In the same number of the *Times and Register* appeared separate reports of successes of electrolysis in urethral strictures by Drs. W. H. Walling, F. H. Wallace, Wm. F. Hutchinson, Wm. R. D. Blackwood, J. B. Greene, Chas. G. Cannaday, O. S. Phelps and R. G. Nunn.

More communications have been received by Dr. E. L. Stephens, Fort Worth, Texas; Wallace, of Boston, and Dr. A. R. B. Booth, of Shreveport, La., who reports one hundred cases, with a complete cure of 80 per cent.

The theory of electrolysis is based on sound scientific principles; it causes a galvano-chemic absorption of the stricture, through the mucous and submucous tissues, by the direct action of the negative pole with weak currents of from 3 to 5 milliamperes.

Practical experiments have demonstrated the electrolytic action beyond a doubt. The theory has been practically applied with good results in thousands of authentic cases.

In the *Times and Register* of Philadelphia, of April 8, 1893, I reported a compilation of 1,755 successful cases by 54 different operators, all of whom vouch for the correctness of their statistics, which proves that the electrolysis under consideration is widely practiced.

The same number of the *Times and Register* brings additional successful cases by Drs. G. Howard McFadden, F. H. Wallace, W. R. D. Blackwood, C. A. Bryce, and from the following editorial is quoted: "The statistics accumulated by Dr. Newman if all were reported, would cover a list of over 2,000 cases of urethral stricture treated by the electric method. In the face of such a mass of positive evidence, one is tempted to explain the dissent existing by the application of the personal equation. Still, every one has his right of opinion and free expression; and if the opponents of this method desire it, the columns of the *Times and Register* are equally at their service."

Dr. F. B. Bishop, of Washington, D. C., has reported more successful cases in the *Virginia Medical Monthly*, June, 1893, in which he says: "After a constant experience of eight years, I am thoroughly convinced that the treatment of the urethra by electrolysis is the best method now known to the profession."

In another part of that article Dr. Bishop says: "Dr. Newman, of New York, has used this method about twenty-six years, and during that time, according to his statement, he has treated numbers of cases with uniform success. Leading surgeons throughout the country have been severe in their criticisms of the Newman method, and have cast a shadow of doubt upon the claims of Dr. Newman. On the other hand, he has been supported by many men of prominent standing in the profession, both in this country and in Europe, who have taken the trouble to master the method, and have practiced it successfully. Some of the critics, I think, have been rather unfair to Newman, inasmuch as they are hardly inclined to give him credit even for sincerity in the report of his cases cured, but content themselves with a wholesale condemnation of his method, because they have tried it a short time and failed to cure their cases."

This most candid statement of Dr. Bishop only proves that some of my critics are unjust in doubting statistics without having any proof to the contrary. My statistics are given in good faith, most of them based on documentary evidence, which consists of publications in medical journals by well-known authors and of original letters in my possession, as well as the evidence of patients, and concurrent opinion of their family physician, either by witnessing the operation or examining the patients before and after the operation; by the final results, no relapses having occurred after patients have been discharged as cured. Some patients have been under observation and re-examinations for eleven years.

Some of these documents are here for inspection, and one particularly will be of interest to show what means have been used to mystify facts.

Permit the introduction here in brief of only one fact: Dr. K., the staff editor of *Genito-Urinary Surgery*, in the annals of the *Universal Medical Science* for 1890, vol. III, Sec. E, pages 15 and 16, tried to make believe that a Dr. Sanders, whose letter I had published, did not exist or was incorrect. That letter was written and published in 1885. With apparent design, after the death of this physician and a lapse of about four years from the date of the letter, Dr. K. wrote a

<sup>1</sup> Bandeller collection.

"polite note" (as he styled it) to that physician. This note, as could be expected, was as politely returned by the postmaster, who evidently declined to assume the responsibility of forwarding it to its destination, and the critical investigator closed his report with the triumphal words: "If the testimony of all the letters in support of electrolysis is no more accurate than that furnished by the letter of F. F. Sanders, it is poor indeed. The inference is obvious, etc."

Now, Mr. President, in answer to this editorial mystification, I am pleased to produce here the original letter of Dr. Sanders, attached to a sworn affidavit acknowledging its genuineness and Dr. Sanders' handwriting. That affidavit is subscribed by a notary public, and the latter's standing as such and his signature is certified by the county clerk, who has affixed his official seal. Next I produce here a letter from the sister of the deceased, who also acknowledges Dr. Sanders' writing and recollects the case he cited. And last, here is a letter from the Secretary of the Medical Society of Morris County, N. J., saying, that Dr. Sanders was well known in Morris County, had been one of the founders of the said Society and in 1885 was elected an honorary member. Now what was Dr. K.'s motive? Is the inference obvious?

All the letters quoted as original are now in my possession as documentary evidence, as well as other evidential matters, but it is impossible to show the same to every member of the medical profession, neither can I have every one certified to by notary publics and county clerks. Therefore I was pleased that the matter has been settled by a committee of this Association, which was appointed to investigate my statistics. This committee have pursued their investigations for nearly a whole year, very carefully and impartially examined the documentary evidence, read the letters concerning it, corresponded with former patients and their physicians in America and Europe. The final report in the transactions of the American Electro-Therapeutic Association for 1893, page 40, was verbatim: "We have examined the records of Dr. Newman's cases and regard his conclusions as well sustained by the statistics, and as far as our experience in this line of work adds further testimony, it is confirmatory of the value of the continuous currents in resolving a large class of urethral strictures, etc."

This report is signed by Drs. A. H. Goelet, Wm. J. Morton and W. J. Herdman. That under some circumstances some medical critics throw doubt on the correctness of the statistics, appears almost as a willful libel.

To succeed with electrolysis in urethral strictures the operator must be a good physico- and physiologic electrician as well as a genito-urinary surgeon. Operators using old methods naturally can not be successful. If some do not succeed with electrolysis, that proves nothing else than the individual failure, which may be due to the operator, false diagnosis, to faulty instruments, and such failures or negative results do not invalidate the records of successes, all perhaps due to ignorance. The old methods in genito-urinary surgery are too severe, and it is to be hoped that the future handling of these cases will be more gentle, with less blood pools, less pain, and less or no cutting.

The principal points in managing urethral stricture are: a correct diagnosis, gentle handling causing no pain; and for the operation of electrolysis, a galvanic battery, good electrodes, the negative electrode used to the stricture, weak currents, long intervals, using only one instrument at a sance, and never to operate while the parts are in a state of acute inflammation.

I can not approve nor adopt some alterations of my method which some electro-therapeutists have proposed, which consist of stronger current, different pole to the stricture, frequent sances and severe measures.

Some have reported good results from faradic currents. My experience is, that the faradism rightly applied may act as an anesthesia and relieve spasm, but it never had any action to absorb or cure a stricture of the urethra.

If operators follow this advice we will hear of less failures, and electrolysis as a chemic action is a fact which can not be denied. Therefore, electrolysis must be a success.

#### DISCUSSION.

DR. BEAVER said that he had used the conical bougie and also the steel sound. He had invariably found on questioning the patient carefully that the current was felt at the spot where the sound entered the stricture. He had been unable to see why there should be any difference in the physiologic effect between the conical bougie and the steel sound, and indeed his experiments had led him to believe that he had obtained cures even more rapidly by the use of the steel sound than by the instrument recommended by Dr. Newman.

On motion of DR. WALKER, the courtesies of the floor were extended to DR. FRANK W. ROSS, of Elmira, N. Y. DR. ROSS said that for eight years he had employed electrolysis for urethral stricture and with success. His attention had been first called to it by a paper read by Dr. Newman before the New York State Medical Association. In the first case, one of acute stricture, he had succeeded with the static current in obtaining relaxation of the stricture and evacuation of the bladder, although he had been unable to pass the smallest catheter into the bladder before this. Since then he had employed Dr. Newman's method of treating urethral stricture by the galvanic current. He thought the medical profession were well aware of the success of this method, and that many physicians were using it. He had tried both the conical bougie and the steel sound and had been more than pleased with the results obtained with both. In conjunction with Dr. Squire, of Elmira, he had treated a number with the steel sound, and he believed the results were better than those obtained by the use of the olive-pointed instrument. The reason appeared to be that all neoplasms offered less resistance to the passage of the current and the tissue was readily absorbed. He also believed a cure obtained by electrolysis was a physiologic cure, while the cure by cutting was not physiologic. He felt positive that the steel sound could be used, although Dr. Newman objected not only to the cure of stricture of the urethra by this means, but to curing them so rapidly.

DR. F. B. BISHOP, of Washington, D. C., said that he thought that Dr. Newman had conferred the greatest blessing on humanity by his method for the cure of urethral stricture. He had employed the method for about ten years, and was well aware that it required experience in the use of electricity as well as in the manipulation of instruments in the urethra. Much care was necessary to avoid causing irritation and spasm, and great caution should be exercised to avoid employing too strong a current. At first he had met with numerous failures, but within the last two years he had been pleased to have those same individuals return to him and be cured. He had never used the steel sound, for it had not seemed to him that there would be a proper concentration of the current on account of the large amount of surface exposed in the urethra.

DR. WALLACE, of Boston, said that he wished to say a word in corroboration of what Dr. Newman had said. He had been using this treatment for the last five years, and could not recall any cases in which he had had better success. He had not used the sound at all. The only difficulty he had found was in cases where it was impossible to get any electrode through the stricture. In cases of stricture of crescentic form, he had found it advantageous to allow electrolysis to take place on the *withdrawal* of the electrode. He had treated some cases in which there was still quite a little inflammation present. Using a current of about 1 milliampère he had found that a few treatments would relieve the irritation and enable him to pursue the treatment more vigorously in the course of a few days. Within the past year he had treated a patient who had been previously treated by urethrotomy twice. Only a No. 7, French, could pass at first, but as a result of electrolysis he was now able to pass a No. 27, French, there was no perceptible sclerosis and he was able to control urination, which he had not been able to do when the treatment by electrolysis was begun.

DR. BEAVER said that the statement which he had made about the use of the sound was not theory but was based upon facts given by the patients, and any one present could verify them. They had all, without exception, stated that the sensation produced by the current was felt at the *location of the stricture*.

THE PRESIDENT said that the physical facts would be rather against the localization of the current in that way. One could not always place much reliance on the statement of patients, especially as regards localizing sensations, and it would seem strange if the current should concentrate itself at the stricture when a large surface of electrode was exposed.

DR. ROSS remarked that it had been demonstrated very clearly that all neoplasms offered such resistance that the current was concentrated in their locality.

DR. DICKSON said that in cases of goitre, if the edges of the clay pad pressed more firmly than the rest of the electrode, a greater effect would be produced by the current at that point. This might possibly explain the patient's localizing the sensation at the seat of stricture. Where there was the closest apposition there would be the greatest concentration of the current.

DR. BEAVER said it had often been his experience that one

edge of an electrode could press more firmly than the rest, and so cause blistering. Although he had treated cases in which the strictures had occupied very variable positions, the sensation had always been localized by the patient as stated.

DR. NEWMAN, in closing the discussion, said that a stricture was a pathologic condition, and if a sound were introduced into the urethra and through the stricture, the pressure that it made against the stricture would be sufficient to explain the fact of the patient localizing the sensation there. One of the speakers had admitted that this method placed in our hands the means of curing by rapid dilatation—this was just what he did not want. The electrical current would be diffused over the whole surface of the ordinary sound instead of being concentrated at the seat of the stricture. What we desire is an electrolytic and absorbent action. With the instrument he devised and employed, the current was not only applied to the stricture, just where it was wanted, but he was able to feel the exact position of the instrument, and without making pressure could ascertain when the current had sufficiently dilated the stricture to admit of the further passage of the instrument. It was this that he desired; it was mechanical pressure that he wished to avoid. The conical sound would pass through and beyond the stricture, and electrolysis would be exerted beyond the stricture and not simply at the stricture.

DR. R. J. NUNN, of Savannah, Ga., read a paper on  
**BEHAVIOR OF CANCER UNDER MILD GALVANIC CURRENTS.**

It is undoubtedly a fact that benign tumors can be absorbed to a greater or less extent through the influence of galvanic currents, although the manner in which the absorption is brought about is still debatable ground among electro-therapists; but observations on the action of mild galvanic currents upon malignant tumors are sufficiently rare to induce me to place before the Association the narrative of the following case:

The patient, a lady of 60 years of age, had had a tumor in the left mamma for about five years before she came under my care. Upon examination, a nodular tumor measuring about two and a half inches horizontally by about two inches vertically was found in the outer side of the left breast. The axillary glands of the left side were enlarged and those of the right side were likewise implicated. The tumor had increased in size very rapidly within the last few months, certainly doubling its size within the last two or three. The patient was cachectic and her general appearance conveyed the impression of grave constitutional disturbances. The kidneys were not involved. It was quite evident that in such a case any course of treatment which would deplete the system or subject the patient to shock was utterly out of the question, and hence surgical interference of any kind, whether by the knife, electric or other cauter, was decided to be inadmissible. Under these circumstances it was determined to try the effects of mild percutaneous galvanic currents applied frequently and in as large quantity as possible.

A sheet-lead electrode with a lint pad extending about an inch in all directions beyond the tumor was prepared, to be used for the negative pole, while a foot bath for the feet and a lint-covered lead electrode for the hands served as positive. Thus arranged, such a current as the patient could bear, varying from 50 to 100 milliamperes, was passed daily. The negative was also applied by the hand electrode to the axillary glands, the whole treatment occupying less than half an hour. Daily for some months this treatment was kept up, and there was then a marked improvement; the axillary glands had almost disappeared and the mammary tumor had not increased in size one particle; it had lost much of its nodular character and the edges instead of being hard and sharply defined were now softened and shaded off into the sound tissue around. But unfortunately my patient could not estimate the progress of the case as did her doctor, and in an evil hour yielding to the glittering promises of a "faith curist," discontinued her galvanic treatment. Again five months, during which the "faith curist" got in her fatal work of inaction and the case returned to me. Now mark the change; the tumor ( $2\frac{1}{2} \times 2$  inches) which had rather diminished and changed in character by five months of galvanic treatment, had now increased to the enormous dimensions of  $13 \times 9$  inches, with an ulcerated surface in the center exceeding in size the original tumor; the left axillary glands were greatly swollen and the whole left arm and hand tumified until it was practically immovable. A small tumor a little more than an inch in diameter

had also appeared in the right breast, and the glands of the right axilla were quite enlarged. The pelvic organs were also involved, and micturition was difficult. The patient now despaired of relief, and was content to make herself as comfortable as possible until the end, which came a few months later.

The conclusion which has forced itself upon my mind through the observations made on this case is, that carcinoma can be benefited by mild galvanic currents of large quantity frequently applied percutaneously.

DISCUSSION.

DR. WALLACE asked if Dr. Nunn had used cataphoresis in connection with the galvanic current. During the past year he had himself employed mild currents with cataphoresis on a case which had been diagnosed by two surgeons as carcinoma. He had used cataphoresis with iodide of potassium, passing the iodine through the tumor. After twelve treatments the tumor began to diminish, and it had now entirely disappeared.

DR. LUCY HALL-BROWN said that probably many of the members had from time to time dispersed tumors of the breast which gave evidence of being carcinomatous, and yet because they had disappeared there had been a doubt thrown on the diagnosis. In the case reported in the paper, the fact that electrical treatment had been interrupted and the condition finally proved fatal prevented any such doubt being thrown upon the case.

THE PRESIDENT said he had had two cases in point. Formerly, he had been of opinion that by the use of from 15 to 20 milliamperes of current these tumors of the breast could be removed. At one time a patient had come to him from Kansas with a tumor of the right breast about the size of an English walnut. The treatment, as outlined, was tried, and he had had the satisfaction of seeing that tumor entirely disappear within two months. From the stinging in the breast and the retraction of the nipple he had felt that it might be malignant. She was told to return if there was any recurrence, and she did so in about six months, with a tumor of about the same size as the first one, and in the same location. A second trial was entirely unsuccessful, and the tumor went on and involved the entire breast. The breast and axillary glands were removed by operation, yet within a year she died of carcinoma of the liver. Recently he had had a second case, which he had at first looked upon as benign. The family history was excellent. The tumor involved the left breast, and was not adherent to the muscle or the skin, and the glands in the axilla were not involved. The electrical treatment was tried almost daily for four or five months, using a current of 20 milliamperes. The only effect was an interference with the circulation about the growth, and the production of slight absorption surrounding the growth, but not of the growth itself. Removal of the breast was advised, but the patient would not consent for two or three months, and at the time of the operation it was found that the axillary glands were involved and that the growth was a carcinoma. He felt that the first tumor in the first case was not malignant, but was perhaps a temporary obstruction of the ducts.

DR. NUNN, in closing the discussion, said he had not used cataphoresis in this particular case. The only value of the paper was to show that the tumor really was a carcinoma, as had been so well appreciated by Dr. Brown. It was because of the certainty of the diagnosis that it was interesting to observe the effect of the electrical treatment.

(To be continued.)

## SOCIETY NEWS.

The American Pediatric Society will hold its seventh annual meeting at the Virginia Hot Springs, May 27, 28 and 29, 1895. The society will be the guests of the Virginia Hot Springs Company.

Address by the President, F. Forchheimer, Cincinnati, Ohio.

Cerebro-Spinal Meningitis in an Infant six days old, by T. M. Rotch, Boston, Mass.

Purulent Otitis Media, which ended fatally (three cases), by Wm. F. Lockwood, Baltimore, Md.

Pyo-Pneumothorax (case), by Walter L. Carr, New York City.

Traumatic Aphasia; Scarlatina Anginosa; Croupous Pneumonia (case), by Samuel S. Adams, Washington, D. C.

Hyperpyrexia (cases), by Henry D. Chapin, New York City.

Sarcoma of Kidney in an Infant (case and specimen), by J. Henry Fruitnight, New York City.

Lympho-Sarcoma of Spleen (case and specimen) by George N. Acker, Washington, D. C.

Tetanus Neonatorum, by J. Lewis Smith, New York City.

Infantile Tetany, by M. P. Hatfield, Chicago, Ill.

Tetany (two cases), by Floyd M. Crandall, New York City.

Amyloid Disease in Children, by B. K. Rachford, Cincinnati, Ohio.

Typhoid Fever in Infants under 2 years—Is it frequent? Wm. Perry Northrup, New York City.

The different forms of Eruption which Simulate Scarlatina, and their differential Diagnosis: *a*, Some forms of Eruption Simulating Scarlatin, by A. D. Blackader, Montreal, Canada; *b*, Scarlatiniform Exanthem, by Charles G. Jennings, Detroit, Mich.; *c*, Scarlatina, with intensified Eruption and poorly marked Constitutional Symptoms (several cases), by Louis Starr, Philadelphia, Pa.; *d*, Extensive Gangrene following Scarlatina, by James C. Wilson, Philadelphia, Pa.; *e*, Difficulty in Differential Diagnosis, by J. P. Crozer Griffith, Philadelphia, Pa.; *f*, Local Treatment of the Skin in the Eruptive Fevers of Children, by A. Seibert, New York City. General discussion.

Case of Adherent Pericardium in Children, with Enormous Heart Hypertrophy, Chronic Proliferative Peritonitis and Recurring Ascites, by William Osler, Baltimore, Md.

A Rupture of the Bladder (case and specimen), by John Dornig, New York City.

Cardiac Anomalies: *a*, Cor biloculare; *b*, Pulmonary Veins opening into Right Auricle; *c*, Imperfect Ventricular Septum in a Man, aged 45 years, by William Osler, Baltimore, Md.; *d*, Aorta arising from the Right Ventricle, by George N. Acker, Washington, D. C.; *e*, Patent Ventricular Septum, by A. Jacobi, New York City.

The Characteristic Features of the recent Epidemic of Grippe—1894-95: *a*, Pulmonary Manifestations; *b*, Aural Manifestations; *c*, Glandular Manifestations. Discussion by L. Emmett Holt, Wm. Perry Northrup and Henry D. Chapin, of New York City, and A. D. Blackader, of Montreal, Canada.

Seibert, New York City.

Cases Apparently Diphtheria, but in which the Diphtheria Bacillus is not found, by E. M. Buckingham, Boston, Mass.

Cases of Scurvy, by A. Jacobi, New York City.

**Chicago Ophthalmological and Otological Society.**—Regular meeting held at the Saratoga April 9, 1895, Dr. Hotz in chair. There were eleven members and visitors in attendance.

The minutes of the last meeting were read and approved.

The applications of Drs. W. R. FRINGER and A. B. HALE were referred to the Committee on Membership.

DR. GRADLE showed a man of 40, who in February, 1895, contracted a severe cold in the head but had no symptoms of grippe. A few days later he had vertical diplopia which, however, disappeared shortly, and the lateral diplopia appeared. When first seen, March 26, with the exception of a slight lagophthalmus, there was no evidence of any paresis of the facial nerve. There was slight ptosis; complete paralysis of the external recti but other muscles all right. To-day he can move eyes outward somewhat. March 26, there was marked vertical nystagmus, now gone, but lateral nystagmus on looking to the side. Some dimness of vision March 26, now gone. Both knee jerks are exaggerated; there is decided fibrillary twitching of the orbiculars; color vision and fields are normal; pupils and fundi normal. Is taking large doses of potassium iodid.

DR. HOLMES had a case, a woman 50 years old, who had very severe paralysis with diplopia following grippe. She recovered under tonics.

DR. MONTGOMERY has a young man, healthy, who had, without apparent cause, paralysis of all external muscles except superior oblique of right eye. He took 700 grains potassium iodid a day without effect, but is now improving under galvanic treatment.

DR. BETTMAN reported two cases of grafting by combined pedicled flap and Wolfe flap. Both cases were very large flaps but adhered nicely with good appearance.

DRS. WILLIAMS, MONTGOMERY, and GRADLE had found that any kind of graft shrank very much in time.

DR. HOTZ prefers Thiersch grafts because they do not leave so much thick skin, except where it is possible to use scar tissue with a pedicle.

DR. COLEMAN reported a case of hemianopsia. Woman, 18 years old, good personal and family history. Seven weeks ago, on awakening in the morning, noticed she could see but half an object; also noticed an appearance as of a lighted match waved before the eyes, producing silvery waves. This was followed in about an hour by pain through the temples and then vomiting of greenish fluid. Had been under medical treatment for a cold or grippe for five weeks and had to stop work. Has had no headache for seven weeks, no loss of memory, feels very well, works as well as before attack. Fundi normal; fields right, up, down, and in, normal; out, contracted to 10 degrees; left, up, down, and out, normal; in, contracted to 5 degrees. V. in each eye 20—15. Wernicke's "hemipic pupil" reaction more marked in right eye. Diagnosis: lesion in visual center posterior to oculo-motor nucleus.

DR. GRADLE spoke of the significance of the odor of the discharge in chronic suppurative catarrh of the middle ear. He had noticed that the disappearance of odor is the first evidence of benefit of treatment. He begins with thorough cleansing, inflation and insufflation of boric acid. If the odor has not disappeared after these treatments he feels sure that the case can not be cured by this method. He then syringes the middle ear by canula if possible; if this does not suffice, he syringes through Eustachian catheter. If necessary, alcoholic or ethereal solutions of iodoform are used and then scraping of carious spots with spoon. He has found peroxid of no more value than water.

DR. WILLIAMS spoke of a case recently examined for color vision, where the man could pick out all the greens, if told to pick out green, but could not pick out all to match the Holmgren green when no name was given. This man also could name a light red lantern without a mistake but called a dark red one, green. This case shows the value of different tests and also of standard colored glass. Dr. Williams also showed a modification of Buissen's photometer.

Society adjourned by limitation.

C. P. PINCKARD, Secretary,

103 State Street.

## NECROLOGY.

JULIUS KAENMERER, M.D., of Atlantic City, died May 13, in the sixty-sixth year of his age. He was a native of Germany, was educated at the University of Heidelberg, studied and practiced at Paris, but came to this country about 1880. He lived in Philadelphia twenty-four years, going thence to the above-named city about twelve years ago. The fatal illness was referred to pneumonia.

JOHN CONDIT HALSEY, M.D., of Brooklyn, died at the ripe age of 80 years, from infirmities due to old age. He was a native of the city named and was educated there and in New York City. In 1834 he graduated in medicine at the College of Physicians and Surgeons, after which date he was for a half century an esteemed family practitioner in the city of his birth. He retired from practice about ten years ago, being led to that step by reasons referable to physical disability. He was one of the oldest living members of the Kings County Medical Society and of the Physicians' Mutual Aid Association.

J. HENRY LEONARD, M.D., of Chicago, May 19, aged 28.—M. H. Henry, M.D., of New York, May 20, aged 59.—G. W. Cooper, M.D., one of the founders of Garnett, Kan., May 16.—F. E. Crosby, M.D., of Jackson, Mich., May 16.—W. H. Winter, M.D., of Princeton, Ill., May 15, aged 69.—G. W. Talbot, M.D., of Denver, Colo., May 15.—J. W. Larrabee, M.D., of Skidmore, Mo., May 10.—Oren T. Maxon, M.D., of Evanston, Ill., May 9.—William Waite, M.D., of Kappa, Ill., May 17, aged 80.—J. H. R. Wolfe, M.D., of Baltimore, Md., May 14, aged 65.—M. S. Coffman, M.D., formerly of San Francisco, at Solomonville, Arizona, May 5.—W. N. Green, of Webster City, Iowa, May 9, aged 39.

Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:  
PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MAY 25, 1895.

A WELCOME ALLY.

What another esteemed contemporary journal<sup>1</sup> styles "the mother of all journals of medical associations," to-wit, the *British Medical*, devotes a leading article in its issue of the 4th inst., to a discussion of the subject of a Department of Public Health for the United States and of the action of the AMERICAN MEDICAL ASSOCIATION to this end. The article is judicious, well-timed and gratifyingly appreciative of the situation. After reciting the various preliminary steps that the ASSOCIATION has taken in this matter, and recognizing the excellent work done in the field of public hygiene and preventive medicine through the agency of different medical departments connected with the public services and scientific bodies, it is contended that the Government can, in a wider way, promote the public welfare by creating a Department of Public Health, "the head of which should be a physician, a member of the Cabinet and on a position of equality with the heads of the Government Departments."

It is shown that the work of such a Department, as set forth in the bill advocated by the ASSOCIATION, may be regarded as covering all that is done by the Medical Department of the Local Government Board in England, by the Registrar-General's Department, and by the Factory Department of the Home Office; and that it is intended to be provided with the machinery for compiling information for the purposes of the various State and other bodies on a multitude of social and health subjects, including the questions of food supplies, intemperance, prostitution, elementary education, etc. The *Journal* adds:

"It is not to be wondered at that the AMERICAN MEDICAL ASSOCIATION and the leading members of other learned bodies in the States should regard this question as one of prominent importance. However the matter may be explained—and we do not doubt that there are certain political explanations—the fact remains that the great nation across the Atlantic is distinctly behind the times in not having a central Public Health Department. Almost every year such departments in older and much smaller countries are being either created or re-organized on such a footing as to make them of real service for the purposes of the public and the State. These departments are also placing themselves more and more in evidence every year by means of annual reports on their proceedings. In the United States the place of such reports has hitherto been largely taken by the annual volumes of the various State Boards of Health, but these vary very much in character, and many of them are coming to be mainly concerned with matters of local interest. It would, however, be otherwise were the vast amount of information available through the State Boards and other bodies sifted and formulated in a form for general use. The States would, under such circumstances, have material at their hand such as few other nations possess."

MR. ERNEST HART recently went to India and stirred up the red-tape animals in that country to good effect in the interest of the profession. Still later—in the last issue of the *Journal* received, that of May 11—he roundly scores His Royal Highness, the DUKE OF CAMBRIDGE, Commander-in-Chief of the British forces, for the manner in which he referred, in an after-dinner speech, to SURGEON-MAJOR ROBERTSON, one of the most heroic of the heroic defenders and relievers of Fort Chitral, as "that brave civilian." MR. HART does not hesitate to characterize the phrase as "a wanton affront to the medical officers of the Army," and boldly warns H. R. H. that the matter will not be allowed to rest, that his dictum shall not pass unchallenged. MR. HART has long been credited with the courage of his convictions, but nothing less than the most profound conviction of the lofty character of the profession, the keenest jealousy for its honor and zeal for its advancement could inspire the courage necessary for this outspoken censure of a Royal Personage. MR. HART may paraphrase the utterance of the poet TERENCE and say:

MEDICUS sum: MEDICINI nihil a me alienum puto.

On behalf of the AMERICAN MEDICAL ASSOCIATION, its JOURNAL welcomes him as a potent ally in our battle for a Department of Public Health.

THE SOCIAL POSITION OF THE MEDICAL PROFESSION.

Every now and then some medical journal gives us a dismal editorial about the social position of the medical profession; about the lack of influence of the doctor in public affairs; about the inferior rewards of a medical career; or about the over-production of doctors; and then each writer falls to wondering why young men will still insist upon studying medicine. The most plaintive and doleful of these lays appear in certain of our contemporaries on the Eastern fringe; and they are pitched in so dismal a strain that one unconsciously feels that the writer must have chronic dyspepsia or a twinge of colic. The British journals have always been the

<sup>1</sup> The Provincial Medical Journal of Leicester, England, May 1, 1895.

loudest croakers on this score—because forsooth the Queen, when she is making peers does not make her PAGETS, and her CLARKS, and her LISTERS, lords or cabinet ministers instead of ordinary knights and baronets, like brewers and bankers and other common cattle—as if the class to which ISAAC NEWTON and HUMPHREY DAVY belonged was not good enough for anybody, or as if it could add anything to the fame of a JOSEPH LISTER to be a cabinet minister or belong to the “PRINCE OF WALES set.” Perhaps our home journals, with just a suspicion of anglomania, take their cue from their British confrères.

These lamentations are as weak as they are indiscreet, and it is hard to find any other reason for it than the inherent tendencies of men to complain. It is hard to get rich in medicine, or to gain social or civic recognition, or to become intellectually prominent, just as it is in every other walk of life. There are too many doctors, as there are too many lawyers, engineers and architects; but in comparison with all these, we trust our modesty will be pardoned, when we say that it has always seemed to us that the doctor had a little the best of the bargain, both in a material and a social way.

As to the doctor's social position, it is not evident that he ever had to sit at the lower end of the table. Great medical men have continually occupied positions commensurate with their abilities. Even in England, where every one, like “little Tommy dearly loves a lord,” it is hard to see where the doctor has failed to hold his own. Going as far back as HARVEY, we find that he was a rich man, the favorite brother of rich London merchants and the associate of his king. Rough JOHN HUNTER was the friend of the courtly SIR JOSHUA REYNOLDS, and RICHARD MEADE a favorite of CHARLES II. SIR ASTLEY COOPER, throughout life a man of commanding social position, when 23 years old married a belle and an heiress—indeed, marrying heiresses has been a favorite avocation of doctors from the earliest times, one which, by the by, shows no sign of abating, and it is nowhere recorded that women, particularly rich women, are careless of social position. SIR HENRY HOLLAND was the acquaintance of all the great men and women of his time and the intimate friend of not a few of them. And coming to the present time in England, MORELL MACKENZIE seems to have stood pretty well with royalty itself. The DUKE OF EDINBURGH and SIR JAMES PAGET have been patrons, side by side, of all the notable charitable functions for twenty years. ANDREW CLARK was the intimate friend of GLADSTONE, who came almost from a sick-bed to give loving testimony to the memory of his dead friend and to the character of the profession which his friend had so highly adorned. And, considering for a moment the continental Europeans, every one at once remembers that BARON LAR-

REY—he of the hip-joint amputation—was the intimate friend of NAPOLEON, who in his last will gave evidence of his sincere friendship by an appreciative message and a bequest of 100,000 francs. In Germany, ESMARCH's wife is aunt to the present Emperor.

As for the social position of the medical profession in America, it would seem that little need be said. As we have intimated, the doctor has usually seemed to us to have a little the best of it. He has certainly held his own from the beginning. DR. JOSEPH WARREN was the greatest loss of the battle of Bunker Hill. Old BENJAMIN RUSH was a signer of the Declaration—and if that isn't simon-pure American aristocracy, will some one please tell us what is? We have never seen any one who had the temerity to question the social position of the WARRENS or BIGELOWS of Boston, or of the DRAPERS, or JANEWAYS of New York, or of the WISTERS, or WOODS, or MITCHELLS, or PANCOASTS, or PEPPERS, of Philadelphia. And, coming down to individuals, take for example, VALENTINE MOTT, or ALONZO CLARK, or WILLARD PARKER, or MARION SIMMS, or FORDYCE BARKER, or POLK, or McLANE, or the FLINTS, father and son, or DRAPER, of New York, or S. D. GROSS, or WM. PEPPER, or H. C. WOOD, or S. WIER MITCHELL, of Philadelphia, or OLIVER WENDELL HOLMES, or HENRY I. BOWDITCH, or J. COLLINS WARREN, of Boston. If there are any gentlemen whose standing in the community is better than these it ought to be made known.

One of the VANDERBILTS married a hospital interne, and we have no doubt that she could not have done better. And—if anything else is needed to make our happiness complete—the brilliant editor of the *Medical Record* was at the GOULD wedding.

But our pessimists say in reply to this, that this is all very nice, but fine words butter no parsnips, and all this has nothing to do with the rank and file of the profession. The fact is the average prosperity of the rank and file is the best answer to these imputations. The rank and file of the medical profession in this country hold a most powerful position. Some of the most enviable places in life that one ever sees are held by family doctors in good towns—and not always in large towns either. The first man in emergencies, the adviser in physical and in the most intimate domestic affairs as well, the one upon whom all depend, at the childbirth and at the bedside of the sick, the equal of any social position and the superior of most in mental and moral endowments, such a man, with his family, leads a life of the most solid satisfaction. His material prosperity is sufficient for his comfort; his surroundings are conducive to independence and happiness; his sons and daughters have good advantages; he himself has the inestimable satisfaction of knowing that he plays a large part in his community; and when he dies he

leaves a void, that if any gap in life were irreparable, would be irreparable. All doctors can not occupy positions like these, but the point we are making is, that in comparison with other men, the doctor has fully his share of these positions of influence and of reasonable prosperity.

We all know full well that the doctor's life is not all rosy; but the lack of social position or influence is not one of its objections. Like other men, the doctor is what he makes himself, socially and otherwise. His profession, if it has any weight as regards his social position is, we believe, rather in his favor. In fact, when one remembers some of the doctors of the type of MARION SIMMS and S. D. GROSS and FORDYCE BARKER—men of their type in large communities and in small—he is inclined to say, paraphrasing Sidney Smith on the strawberry, that doubtless God might have made a better man than a good doctor, but doubtless he never did.

#### THE EDUCATION OF THE JAPANESE HOSPITAL CORPS.

There is no reason why the Hospital Corps men of the Japanese Army should not be thoroughly educated, for ample provision in the way of books has been made for them. Three text-books on military nursing have been issued, and one on the use of the stretcher. The three are apparently graded and are probably intended for those who in Japan are the equivalents of our private, acting hospital steward and steward, as one consists of only 140 pages, while the second has 280 and the third 600 pages. To the professional eye, educated in the medical lore of our western civilization, the text of these volumes, consisting of pot hooks, hangers, gridirons, harps and other complicated hieroglyphics, conveys no suggestion of the subjects discussed.

Indeed a casual observer might consider the end of each book to be its beginning; but they are all so profusely illustrated that the said professional eye experiences no difficulty in following the whole subject from its beginning where we usually print "finis," to its end, where we usually have our title page. Most of the illustrations show their western extraction in the facial characteristics of the individuals represented, and on some are to be found our familiar Arabic numerals on points calling for explanatory text. There are, however, some original Japanese cuts, particularly in the litter-drill book. The largest volume contains most of the illustrations found in the others, excepting some of those relating to stretcher drill. First, we find full page front and back views of the male figure, with western numerals over the swelling masses of the well-developed muscles. Then follow the skeleton; the teeth showing crowns, bodies and fangs; the *écorché*, or flayed figure, teaching the location of

the superficial muscles; the circulation through the heart and through the body, pulmonary and systemic; vertical sections of the eye and ear, and the thoracic and abdominal viscera *in situ*.

Thus far anatomy and physiology have evidently been discussed; but now we come to matters of practical interest: hemorrhage controlled by forced flexion at the elbow; digital pressure on the femoral, brachial, subclavian, carotid and facial arteries; the tourniquet on the brachial, ESMARCH's tubing on the femoral and a handkerchief twisted by a sword bayonet over the same vessel. Dressings follow: the arm sling; four-tailed bandage for the chin; the triangular bandage with its pictures which ought sufficiently to explain its use, but these are supplemented by special cuts showing its application to the shoulder, elbow, hand, ankle, groin, scalp, etc.; the roller and its reverses on various parts of the body.

Next, fractures come in for consideration as evidenced by a wire cradle, metal leg splint with foot piece, extension by weights and SMITH's anterior applied. SYLVESTER's method of artificial respiration is illustrated, both at inspiration and expiration; but if MARSHALL HALL is mentioned his name must have been translated into unrecognizable hieroglyphics.

Field work follows: litters extemporized of poles and cords, rifles and overcoats; carrying patient to litter; two- and four-handed seats. After this, for nearly three hundred pages, the only illustrations are a spring scarificator and a cupping glass; military nursing is no doubt being discussed. The litter drill book repeats the anatomic illustrations and those relating to hemorrhage bandaging, etc. It shows the position of the squad at the open and closed litter and the wheel of the litter in changing direction. From the illustration showing the squad placing a patient on the litter, it is manifest that the Japanese Hospital Corps have not learned the best way. They rise with the patient to the erect attitude, in order to lay him down on a litter almost on the ground level. Truly, a doctor can gather much information from these volumes, although not a single word is intelligible to him.

#### THE HORNED MEN OF AFRICA.

For many years reports have been current of the existence of horned men in West Africa. In 1883 PROFESSOR MACALISTER, then of Dublin, now of Cambridge, collected the evidence accessible at that time.<sup>1</sup> At first the growths were thought to arise from the superior maxilla, and as this region is well known to be a favorite site for exostoses, it was supposed this so-called horned condition was caused by symmetrical exostoses. MR. JONATHAN HUTCHINSON has published in his "Illustrations of Clinical Surgery" a

<sup>1</sup> Proceedings Royal Irish Academy.

figure of a male European thus affected which closely resembles that of a horned man furnished by MACALISTER.

A great deal of light has been lately thrown on this condition by M. MACLAUD, a French naval surgeon serving on the Ivory Coast. In the *Archives de Médecine Navale et Coloniale* this author gives an account of seven cases he has observed. The affection is termed by the natives *Goundou* and *Anakhre* (big nose) in the Aquí language. His cases ranged from 8 to 65 years in age, and the tumors had existed from a few years up to thirty years. M. MACLAUD had one man under observation for several months, and describes the tumors as being symmetrical, as large as a hen's egg on one side and as a large nut on the other; they were ovoid, hard—a hypodermic needle would not pierce them—circumscribed, and occupied the lateral walls of the nose, extending from the root to the canine fossa, making part of the nasal, lacrymal and superior maxillary bones. There was no trace of tuberculosis, syphilis, leprosy or glandular swellings. Examination of the nasal fossæ showed the tumors to encroach on them. Smell was intact, but nasal respiration was embarrassed. Percussion of the tumors showed them to be hollow. This individual was a slave 20 years of age, who had been captured and carried to the Aquí country when about 8 years old—the tumor beginning to grow in a year's time after his arrival. The author mentions another case as being a horrible sight; this was an old man with a tumor on one side as large as an ostrich egg, on the other as a large orange; vision on the side of the larger one had been abolished for years, and the right eye had been forced from its orbit by the growth.

The affection begins in late childhood by epistaxis, cephalalgia and sometimes a muco-purulent discharge from the nostrils. At first the tumor is no larger than a bean, but, slowly increasing, is as large as an almond at 15, a pigeon's egg at 20, and so on. It never suppurates, and apart from the destruction of vision does not seem to occasion any inconvenience. M. MACLAUD thinks it probable the condition arises from lesions produced in the nasal fossæ by the larvæ of flies. He points out that the disease is not hereditary, and that it is confined to the forest region where flies abound. On his way home he saw a chimpanzee affected in a similar way, but lack of time prevented an investigation. The natives account for its origin by attributing it to the malevolence of a fetich *Jero* or *Zoré*, a statue of which carved in wood bears similar swellings; if appealed to too often the fetich, becomes irritated and inflicts these horns upon the annoying supplicants. Owing to this supernatural origin they use nothing save the usual remedies for all diseases—cataplasms of pimento or aromatic plants, bathing with pimento, etc.

In concluding his highly interesting paper, DR. MACLAUD states that one or two cases may be found in any village of 100 or 150 inhabitants.

#### A NEW ARMY STRETCHER.

A board of which COL. CHARLES H. ALDEN is President was convened at the War Department some time ago to investigate and report upon the form of litter found to be best suited for Army use, having in view economy, simplicity of construction, durability, lightness and adaptability for the services required. The board has submitted a new model for the consideration of the Surgeon-General, who, it is understood, will bring the specifications and a litter constructed in accordance with them, to the notice of the U. S. Military Surgeons at their meeting in Buffalo, N. Y.

The main object of the board was to lessen the weight of the litter without impairing the strength of any of its essential parts. The present regulation litter weighs twenty-four pounds; but the new model weighs only sixteen and one-half pounds, and if adopted will be the lightest military litter in any service.

The litter poles are made one and a half inches wide instead of one and three-quarters; but the depth on which comes the greatest strain remains one and three-quarters as formerly. The canvas is practically the same as that of the regulation litter, but it is so fastened to the poles as to be flush with the wood and thus less exposed to be ripped off. The feet are stirrup-shaped, of malleable iron; the cross braces of well-tempered steel. The pole plate of each foot is fastened by a single bolt and it is turned up at the sides to grasp the pole. The foot plate, which is slightly convex in every direction, raises the under surface of the pole four inches above the ground level. The braces play on the pole plates of the foot pieces and are hinged in the middle, with a fenestrum behind the joint to prevent clogging with mud or dirt. They are grooved longitudinally on four aspects to lessen weight, and provision is made for keeping them in place beneath the poles when the litter is closed. The sling is of strong webbing, the color of the bearer's blouse, and is to be worn by him as part of his equipment when on litter service. It has a leather-lined loop at each end to catch the handles of the litter and is adjustable to the height of the bearer by a sliding buckle.

The new model has been tried by CAPTAIN CABELL, of the Hospital Corps Company, at Washington Barracks, and has given satisfaction. The present sling is attached to the handles of the litter. The adoption of the new model litter and sling would necessitate a revision of the Drill Regulations of the Hospital Corps, as most of the intricacies of the present drill are provisions for getting into and out of the attached sling and for preventing its bight from doing harm

when not over the shoulders of the bearer where it always ought to be.

#### NOMENCLATURE OF PREGNANCIES.

DR. GEORGE M. GOULD, the erudite philological editor of our valued contemporary, the *Medical News*, protests against the terms: ii-para, iii-para, iv-para, v-para, etc., used to designate a multi-para in her second, third, fourth or fifth pregnancy, and thinks it strange that the remarkable fecundity of the medical lexicographers has not been equal to the emergency of devising names for these simple facts instead of designating them by a set of unpronounceable monstrosities. With what he calls "proper fear and trembling," DR. GOULD suggests the substitution of coinages made upon the same plan as similar words accepted and in general use. "Possibly this has already been done. We now have the words, nullipara, primipara and multipara. Why should we not also have duipara (or deutipara), tripara, quadripara, quintipara, sextipara, septipara, octipara, nonipara, decipara?" Why not, indeed? Unless medical language, like the language of diplomacy, is to be used to conceal and obscure, there is no occasion for timidity in offering these valuable substitutes for the impracticable cacophonies now in use. DR. GOULD has made another distinct addition to clearness and simplicity in medical terminology, and the JOURNAL promptly accepts it.

#### A MISAPPREHENSION.

Some of our lay contemporaries have animadverted on the clause in the report of the Trustees which gave the net cost to the ASSOCIATION of the JOURNAL as \$12,000. The explanatory fact that over one-half of this amount was expended in new machinery, seems to have been overlooked, although it was plainly stated in the report.

But the great point that nearly the whole edition was *given* to the members without additional cost was nowhere stated, as it was supposed the members knew that. Subtracting the cost of the new machinery from the total cost to the ASSOCIATION Treasury, it is apparent that the net cost of the JOURNAL to the members was less than \$2 each, for a JOURNAL worth \$5.

No journal has published more material during the year; few have been better on the whole. Taking therefore the facts as they stand, it is seen that the members have every reason to congratulate themselves on the financial showing made by their JOURNAL.

If we could only raise the list to 10,000, the proportionate drain on the treasury would be infinitesimal. Let every true friend secure one new member by application, or one new subscriber, and the JOURNAL will not only be a still better JOURNAL, but it can be given to every member, at an even less cost.

## CORRESPONDENCE.

### The U. S. Pharmacopœia.

SHELBYVILLE, IND., May 16, 1895.

*To the Editor:*—In the JOURNAL of April 13, I notice a letter from Dr. W. P. Whery, of Fort Wayne, Ind., under the title, "Of What Use is the Pharmacopœia?" I have waited this long, hoping some one more able to do so than myself would reply to it.

While I do not, for a moment, think such an excellent work as our present Pharmacopœia needs any defense at my hands, I shall point out a few of the most glaring inaccuracies in the article referred to. I shall also attempt to show that the U. S. Pharmacopœia has, at least, *some* excuse for its existence, and that it is *the* authority upon "questions pharmacæutic." In the first place, the U. S. Pharmacopœia is a work of great value and is *the standard* from which *all pharmacists* work in making their various preparations such as tinctures, fluid extracts, syrups, solutions, etc. Does not the Doctor know that when a prescription is written for tincture iodine, tinct. gentian, syrups, etc., that it calls for a preparation of a definite strength and prepared in a certain way, and that the *standard* by which those preparations are made is the U. S. Pharmacopœia? If not, how are we to know anything about the strength of any preparation we may prescribe or about the *dose* of the same? Does he not know that the pharmacist uses the Pharmacopœia in making his preparations? and that it is his *sole guide* in so doing?

I know that during my experience as a prescription clerk, I always strictly adhered to it as my guide in making up the various preparations. I would also like to ask if the Pharmacopœia is of no use, as the Doctor says, why is it so universally used in this country?

I do not mean to say that I think the book is perfect, for no such book can be made so. If physicians, generally, would study their Pharmacopœia more, and the literature sent out by manufacturing houses less, they would be far better off and could serve their patients better.

In answer to the question, Of what use is it? I will say, a Pharmacopœia is a book containing a selection of medicinal substances with formulas for their preparation. The necessity for legalized standards to define the character, establish the purity, and regulate the strength of medicines is recognized by all civilized nations. Remington's Pharmacy (page 26) says: "The official pharmacopœias are all issued under the authority of the respective governments, with the exception of the U. S. Pharmacopœia (which has, however, been accepted by the government as a standard in some of the departments), the policy of the nation having been against interference in matters which relate to restrictions upon professional practice. This course has not prevented the acceptance of the work by physicians and pharmacists as an authoritative guide, while it has probably encouraged a greater freedom in criticism, and thus developed more general interest in a standard, and a stronger desire for improvement than could have been obtained through compulsory legislation."

Dr. Whery begins his letter: "I do not wish to disparage the United States Pharmacopœia in the least, nor to detract from the great merit of a work involving so much conscientious care and science and labor on the part of its authors, but I think I voice the feeling of the profession generally when I ask the question written above."

In another portion of his tirade he says: "Under these circumstances the Pharmacopœia seems to be out of gear with the times, and is to be looked on as a kind of survival from the past, like the great auk and the woolly rhinoceros. Yet it is quite possible that there is still a place for a United

States Pharmacopœia, provided that the book can be made to suit the conditions of these days. Until then, it is only an expensive luxury, and an unnecessary imitation of works that—under the different laws of European countries—may have some good right of existence.”

Now let us look at these two statements. Dr. Whery does not wish to “disparage,” and then *attempts* to do so. Let me ask *why* the U. S. Pharmacopœia is an “expensive luxury?” *Why* is it “out of gear with the times?” In what way is it so? Please specify. *Why* does “it not suit the conditions of these days?” Perhaps he has been reading an edition thirty or forty years old. He intimates that the U. S. Pharmacopœia is an “imitation.” If so, *of what?* Again, if it is an “unnecessary imitation” of some foreign pharmacopœia *why* is it “a work involving so much conscientious care and science and labor on the part of its authors?”

During the past eight or ten years, I have had an opportunity of examining a number of pharmacopœias of different nations, and I believe ours is *second to none* and, above all things, it is *original*.

The Doctor would also like to know, “what number of physicians use it in their practice?” I am sorry I can not inform him as to the exact number, but I believe that *all* of the educated physicians who have a conscientious desire to be good physicians and to benefit their patients use it as their guide. As for myself, I have the latest edition and use it frequently too.

The Doctor would also like to know “what drugstore confines itself to the U. S. Pharmacopœia or cares for it as an authority?” I believe the pharmacists *all* use it as their *sole guide* in making up the various preparations such as tinctures, syrups, etc. For any information on this subject I would respectfully refer the Doctor to Mr. Otto Gross, of his own city, whom I know to be one of the best as well as one of the most progressive pharmacists in Indiana. I would like to ask the Doctor what the pharmacists use as their guide if they do not use the U. S. Pharmacopœia? They *must* use some guide, and I would like to know *what it is*.

Dr. Whery is evidently attempting to place the pharmacists on a level with the grocer, hardware merchant and other tradesmen, instead of elevating them to their proper position as a profession. As for myself, I have too much respect for pharmacists in general to believe that they *buy* such things as tinctures, syrups, spirits, waters, etc., instead of preparing them in their own store.

The Doctor, evidently, has not been keeping in touch with progress in pharmacy, as the following will clearly show: “In the United States there is no legal control of pharmacy.” In reply to this assertion, it is only necessary to say that *every State* in this broad land of ours (except Indiana), has a pharmacy law; Indiana is now the *only exception*, and it is to her lasting disgrace that it is so. The Doctor asks: “What medical college uses the Pharmacopœia as a text-book for teaching *materia medica*?” While I do not know of any medical college that uses it as the *exclusive* text-book upon this branch, I do not know of a medical college that does not use it as *one of the text-books* upon *materia medica*. I would like to ask the learned (?) Doctor *how* “the profession—including pharmacy—has emancipated itself from the Pharmacopœia?” If all he says is true, *why* should “we regret to give it up?” In *what way* should it be “recast?” What is the matter with its “present form?”

The Doctor says: “More regard must be paid to the convenience of prescribers; the confusion between waters, liquors, and solutions, syrups, elixirs, and glyceroles, tinctures, wines and spirits, and so on, should be abolished.” How pay “more regard to the convenience of prescribers?” What *does* he mean? I am sure that if there is any “confusion” between these preparations it exists only in the addled

brain of the writer. I shall here give a concise definition of each of these preparations in order that he may know what each is and there need be no more “confusion.” However, before proceeding further, I want to quietly give the Doctor “a pointer” or two. Don’t ever again make the mistake of saying “liquors *and* solutions,” for it is two names for the same thing. You should say liquors *or* solutions. I also want to call his attention to the fact that there is no such class of preparations in our Pharmacopœia as “glyceroles.” I suppose he means, *glycerita* or *glycerites*. They are mixtures of medicinal substances with glycerin. In regard to the difference in name, I quote the U. S. Dispensatory, 17th Ed., page 654: “The solvent and preservative properties as well as agreeable taste and permanent consistency of glycerin render it useful as a menstruum in pharmacy, and a class of preparations consisting of medicinal substances dissolved in it has come into extensive use. The British Pharmacopœia has adopted such a class under the name of *glycerina* or *glycerines*. This title is not now available because these terminations are reserved for alkaloids, while the term *glyceroles*, adopted by the French, is objectionable, as the termination has been used as a designative of certain proximate principles. But the United States title *glycerita*, or *glycerites* is satisfactory.”

“Aguas” or “waters” may be simply defined as aqueous solutions of volatile substances. “Liquors or solutions” (not “liquors *and* solutions”). Under this head the U. S. Pharmacopœia places all aqueous solutions of non-volatile substances, except such as naturally form separate distinctive classes, as the syrups, infusions and decoctions. Solution of gutta-percha is the *only one* in the class which is not prepared with the solvent, water. Syrups are concentrated solutions of sugar in water or aqueous liquids. When water alone is used in making the solution of sugar, the preparation is called syrup or simple syrup. When the water contains soluble principles from various medicinal substances, the syrup is called a medicated syrup. Elixirs are aromatic, sweetened, spirituous preparations, containing small quantities of active medicinal substances. Tinctures are alcoholic solutions of medicinal substances. They differ from “spirits” in being made from non-volatile bodies, there being but one exception to this rule. Wines are liquid preparations containing the soluble principles of medicinal substances dissolved in wine. Pharmaceutically they most resemble “tinctures,” differing from them merely in the character of the menstruum. Spirits from a pharmaceutic point of view are simply alcoholic solutions of volatile substances. Like the medicated waters, the active ingredient may be solid, liquid or gaseous.

Dr. Whery says: “Powdered extracts, tablets and troches should be recognized.” If he will examine his Pharmacopœia he will find troches *are* recognized under the name, trochisci *or* troches. As for powdered extracts, they are not recognized and *should not be*. It is a well-established fact that they can not be made of a uniform strength and are consequently worthless. Tablets should not be recognized, as they are a passing “fad,” and I venture the assertion that ten years hence they will be practically unknown, as they possess no feature that is an advantage over the old-time preparations.

I do not believe “we want a more extensive list of remedies,” as there are already too many. In conclusion, allow me to quote a few more lines from the Doctor’s remarkable letter: “A third use would be to reinforce the decimal system of weights and measures in medical usage; and to accomplish this, a new weight, the deci-milligram, should be added, and the system must be made to conform to the teaspoonful until the domestic and convenient measure can be eliminated.”

This surely caps the climax. It seems to me that the decimal system of weights and measures *has been enforced to its fullest extent*, as it has been adopted as the *only* system in our Pharmacopœia, the old system having been *entirely elim-*

inated. What more can be done to enforce it? Why not make the teaspoonful, etc., conform to the decimal system, instead of the opposite course? Why derange the decimal system? I do not see the connection between a deci-milligram (?) and a teaspoonful. In the metric (or decimal) system the meter is the unit of length, the liter is the unit of capacity, and the gram is the unit of weight

A gram is . . . . .	15.43	grains.
A decigram is . . . . .	1.543	"
A centigram is . . . . .	.1543	"
A milligram is . . . . .	.01543	"

A deci-milligram would be .001543 grains, or expressed in fractions it would be 1543-1,000,000 of a grain.

A teaspoonful is a measure of capacity, not weight, and is usually given as 1 fluidrachm. Now what I fail to detect is the connection between 1543-1,000,000 of a grain and a teaspoonful or 1 fluidrachm. Will the Doctor explain himself? And, beside, to be in conformity with the metric system, would it be proper to say a deci-milligram, when the unit of weight is a gram, not a milligram? I am of opinion that deci-milligram will not do, but that it would take another word to express what he means.

I am very sorry the Doctor wrote his letter, as the U. S. Pharmacopœia is now completely annihilated and we shall hear of it no more!

SAMUEL KENNEDY, PH.G., M.D.

### To Bacteriologists.

MINNEAPOLIS, MINN., May 14, 1895.

To the Editor:—Will you kindly state in your next issue that a vacancy exists in the Chair of Bacteriology in the College of Medicine and Surgery of the University of Minnesota. Applicants for the vacancy can apply to Prof. Thos. G. Lee, chairman of the committee to nominate a person to fill the vacancy.

PERAY H. MILLARD, Dean.

## PUBLIC HEALTH.

**Disinfection of Localities.**—MM. Laveran and Vaillard announce that from their experiments they believe the best method of disinfecting the walls of habitations consists of first washing the walls with soapsuds, then with a 5 per cent. carbolic acid solution or 2 to 1000 of sublimate, acidulated. In all localities which are exposed to frequent soiling—hospitals, barracks, schools, hotel rooms, etc., the walls should be of impermeable material, easy to clean and disinfect. If sprays are used the liquid should be made to stream along the walls, but in this way the disinfection is often imperfect. The carbolic solution is preferable to the sublimate it seems.<sup>1</sup>

**Fencing from a Hygienic Standpoint.**—According to Lecomte fencing is a hygienic exercise of the first rank and even a curative means for certain deformities. This exercise should be practiced in a well ventilated room, under the direction of a *maitre d'armes*, who insists on the correct execution of the movements and unrestrained postures. It is indispensable to use the left hand also, in order to develop the two sides of the body equally. Under the influence of this exercise the muscles develop, the joints and spinal column are suppld, the respiratory, circulatory and digestive functions are rendered active; nutrition and the nutritive changes are stimulated at the same time as the cutaneous functions. Fencing has given excellent results in hysteria, chorea, migraine, hypochondria, insomnia, obesity, gout, rheumatism, constipation, and chlorosis. It assures recovery from scoliosis and from stiff joints following immobilization, and corrects certain cachectic deviations of the lower limbs.<sup>2</sup>

**Sanitary Climatology.**—Circular No. 4, of the Weather Bureau, containing information relative to the investigation of climate on health, previously noted in the JOURNAL, furnishes blank forms of the reports desired. They seem to be

simple, compact and yet sufficiently comprehensive. Supplies of the forms and of the blank envelope may be obtained by those interested on application to the Bureau. It is intended to collate the vital statistics thus obtained with the meteorological statistics by general averages and by particular and selected events, as the comparison of the general mortality with the average conditions of the weather for the week, and the passage of storms and cold or hot waves, the appearance of epidemics, etc. Also, in instances of well-defined weather disturbances, comparisons of vital and meteorological statistics will be made by daily periods. For example, a storm appearing in the western part of the country, will be followed day by day, as it passes eastward across the country, and the illness and deaths reported for these days from the localities traversed will be compiled and compared with the same kinds of facts reported both before and after the storm. The same plan of treatment will be pursued in dealing with hot and cold waves. By these methods it is hoped to be able to give in time, definite information as to how and how much the accidental and constant variations of the weather affect the sick and well, and in what way the present forecasts and weather charts can be used in both curative and preventive medicine.

**Health Reports.**—Sanitary reports to the Supervising Surgeon-General, Marine-Hospital Service:

#### SMALLPOX—UNITED STATES.

Arizona: Nogales, May 12, 1 case.  
Missouri: St. Louis, May 4 to 11, 11 cases, 2 deaths.  
New Jersey: Hoboken, May 4 to 11, 1 case.  
Ohio: Cincinnati, May 10 to 17, 5 cases, 3 deaths.  
Pennsylvania: Philadelphia, May 4 to 11, 2 cases, 1 death.  
Wisconsin: Milwaukee, May 4 to 11, 8 cases, 1 death.  
Virginia: Staunton and vicinity, to May 19, 59 cases.

#### SMALLPOX—FOREIGN.

Belgium: Antwerp, April 13 to 27, 3 cases, 1 death.  
China: Hong Kong, March 31 to April 1, 1 case.  
England: London, April 27 to May 4, 1 case, 1 death;  
Manchester, April 20 to 27, 1 case.  
Germany: Prague, April 20 to 27, 4 cases.  
Holland: Rotterdam, April 27 to May 4, 3 cases, 3 deaths.  
Ireland: Dublin and suburbs, April 27 to May 4, 17 cases, 2 deaths.  
Russia: Moscow, April 20 to 27, 2 cases; Odessa, April 20 to 27, 5 cases; St. Petersburg, April 20 to 27, 7 cases, 2 deaths;  
Warsaw, April 13 to 20, 1 death.  
Scotland: Edinburgh, April 20 to 27, 5 cases.  
Turkey: Constantinople, March 1 to 31, 97 deaths.

#### CHOLERA—FOREIGN.

Japan: Hiogo, April 13 to 20, 1 case.  
Turkey: Constantinople, March 1 to 31, 60 deaths.

#### YELLOW FEVER—FOREIGN.

Mexico: Vera Cruz, May 2 to 9, 3 deaths.

**Yellow Fever.**—A dispatch of the 18th inst. from Havana says that the stories circulated in regard to the prevalence of yellow fever among the troops operating against the insurgents are greatly exaggerated. According to the official records there were only 27 deaths therefrom reported up to May 18, although 200 soldiers had been treated for various diseases. *Per contra*, Surgeon-General Wyman, of the U. S. Marine-Hospital Service, on his return from a tour in the South which was extended as far as Havana, reports that yellow fever is quite prevalent on the island, especially about Santiago. Dr. Wyman personally visited several of the United States quarantine stations along the Gulf of Mexico and along the Atlantic coast north of Florida. Arrangements were perfected all along the seaboard as far as possible for a rigid enforcement of the United States quarantine regulations. Dr. Doty, Health Officer of the port of New York, confirms the assumption that the deaths on the steamship *Hogarth*, from Santos, were from yellow fever, and the disease, of a severe type, is epidemic at that Brazilian port. The action of Dr. Porter, State Health Officer of

<sup>1</sup> Jour. de Pharm. et de Chim.

<sup>2</sup> These de Paris.

Florida, in enforcing quarantine regulations upon the Spanish cruiser *Infanta Isabella*, recently arrived from Havana, has excited considerable discussion and the Secretary of the Treasury was finally compelled to issue an order for the warship's release.

**Secret of Long Life.**—The *Journal d'Hygiene* recently commented upon the habits of life and the regimen by which three doctors—Drs. Baynes, de Boissy and Salmon—have reached or passed the centenary of existence; one of them at least, still in the practice of his profession, in his hundredth year, and the two others said to be still hale and hearty at the ages of 103 and 105 respectively. M. Jules Hoche, a French humorist, has analyzed the *Journal's* report with a view to discovering the secret of this remarkable longevity, and finding nothing definite therein, offers a few rules of his own as follows: First, never be sick; that is an essential condition; because sickness is, in principle, hostile to good health, which is the mother of longevity, by the same right that prudence is the mother of certainty. Secondly, never have any bile, because bile is the vehicle of all unhealthy humors, as the world knows since the time of Hippocrates. Thirdly, fall in love as little as possible. This is a very important point, because all the definitions that people have given of love up to the present time are inexact. To love is to give a little of one's life to somebody else, a liberality all the more absurd because the donor has no title to that which he gives, and it is evident that to waste one's life is to reach bankruptcy in short order. In this matter avarice is legitimate, because it is a matter of self-defense. From the elementary point of view, the only possible indications are presented by themselves: never eat except when you are hungry and never drink except when you are thirsty. As for sleep, it is beyond a doubt that one should never resist it, even through politeness. The essential is to sleep soundly as many times as you can, because to sleep is to economize vital force. Therefore, it is plain that to live long, we must in the first place be in good health; that to be in good health we must never be sick; and that in order to avoid sickness, it is absolutely indispensable to be in good health.

**The United States Public Health Department.**—For some years past it has been a prominent aim of the AMERICAN MEDICAL ASSOCIATION to secure for the United States a central Government Department of Public Health, and preliminary steps have from time to time been taken to memorialize Congress to create such Department, together with a State-paid Medical Secretary. Once again the ASSOCIATION brings the matter forward in the form of a memorandum to the Senate and the House of Representatives, prepared by the Chairman, Dr. C. G. Comegys; and appended to this document is a draft Bill to give effect to the object referred to. It is admitted that much excellent work is performed through the agency of different medical departments connected with the Army, the Navy, and different scientific bodies; but it is contended that Government can, in a wider way, promote the public welfare by creating a Department of Public Health, the head of which should be a physician, a member of the Cabinet, and on a position of equality with the heads of the Government Departments. Under Section 2 of the proposed Bill the work of the department is set out. It may be regarded as covering all that is done by the Medical Department of the Local Government Board in this country, by the Registrar-General's Department, and by the Factory Department of the Home Office; and it is intended to be provided with the machinery for compiling information for the purposes of the various State and other bodies on a multitude of social and health subjects, including the questions of food supplies, intemperance, prostitution, elementary education, etc.

With regard to the organization of the Board, we believe the ASSOCIATION is right in demanding that its head and its

executive officers should be medical men. Indeed, we have heard only one valid reason for a change in the same direction in this country. It is said that if a new department in Public Health were created it would be the youngest department in the State and would have to rank as such. But the Local Government Board, which has public health functions in addition to a multitude of other duties, is gradually becoming a Ministry of the Interior, and it is assumed that when its position as such in the State is fully recognized it will probably absorb one or two functions still performed by other departments, and its chief will be raised to the position of a Secretary of State. This is the ambition of the secondary State departments in this country, and there are those on the permanent staff of the Local Government Board who would resent the severance from the board of its public health functions, for such severance would diminish its importance and cut adrift a staff which, to say the least, has brought them some credit in the eyes of the public. In the States no such considerations as these arise, and it is to be hoped that the new department when created will be mainly in the hands of those who best know what is wanted for the control and the improvement of the health of the public.—*British Medical Journal*, May 4, 1895.

## MISCELLANY.

**Change of Address.**—Dr. Edwin J. Kuh to 3415 Prairie Avenue, Chicago.

**They Understood the Language.** (From *Judge*):—HE—"Doctor, every time I raise a hand I'm completely knocked out with pain."

DOCTOR—"Then you had better play some other game."

**Sunstrokes in England in May.**—On May 14, while Americans of the northern tier of States were taking again to their overcoats, the English suffered from a hot wave. We learn by cable that, at Portsmouth, where four thousand troops were on parade, the heat was abnormally intense, and ten men were sent to hospital on account of sunstroke.

**A New York College Commencement.**—At the thirty-second graduation exercises of the New York Medical College and Hospital for Women, held May 14, ten degrees were issued, and eight or more prizes awarded to the graduating and inferior classes. The addresses were nearly wholly by the female friends of the school.

**An Aluminum Canteen.**—The military journals announce that the Ordnance Department of the Army has had submitted to it for test a canteen made of an alloy of aluminum. The canteen, in shape, is somewhat like the one at present in use in the Army. The authorities are said to be much pleased with it, and there is therefore a strong chance of its adoption.

**Michigan in Line.**—A bill to regulate the practice of medicine in the State of Michigan and to create a Board of Registration therefor has become a law. The Board, which is to begin operations July 1, is to be composed of four regular physicians, two "homeopaths," two "eclectics," and two "physio-medicals." The law is not retro-active, all physicians in practice in the State July 1, and all having diplomas from reputable colleges, being entitled to registration.

**Jenneriana.**—With the approach of the Jennerian centenary, and concerning the discoverer and his discovery are beginning to multiply. The celebration of the seventy-sixth anniversary of Queen Victoria's birthday, on the 24th of the present month, has led one of her biographers to unearth the fact that she was vaccinated in September, 1819, being then about four months old, and that she was the first member of a royal family to be subjected to the operation.

**A Too Radical Improvement.**—From the *Toronto Truth*:—The physician was surprised to find the head of the household at the door with a shotgun.

## ADDRESSES.

### ADDRESS ON STATE MEDICINE.

Delivered at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore, Md., May 7-10, 1895.

BY HENRY D. HOLTON, A.M., M.D.

BRATTLEBORO, VT.

*Mr. President, Members of the American Medical Association:*—Hygiene is as old as the profession of medicine. But "State Medicine" is of comparatively recent origin. We find the leader of Israel promulgating sanitary regulations for his people that can hardly be improved to-day. Greeks and Romans honored the sanitarian and gave much time to the study of subjects connected with matters pertaining to public health. Pure air, pure water were deemed by them to be a great desideratum. The Aztec erected aqueducts to supply the City of Mexico with pure water long before Columbus sailed from Palos. But amid the wreck of the Dark Ages the little that had been taught regarding the necessities of hygiene to public health was buried, and only in the last sixty years has its resurrection and reestablishment upon a firm and more enduring basis been attempted. The early pioneers of our profession in this country were alive to the importance of hygiene; especially was this true of the Sydenham of America, Dr. Benjamin Rush. With the pressure resting on him of the multitudinous and arduous duties of practitioner in hospital and family, as statesman, lecturer and author he found time to investigate and write upon epidemic diseases in a way that showed the most accurate observation and current discrimination of facts bearing upon sanitary science. His work in this direction was recognized all over the world and caused the Czar of Russia to present him with a diamond ring, as a token of appreciation for the valuable service rendered the world by his observations. Yet the profession of America have so far failed to avail themselves of the high privilege accorded them to contribute a sufficient sum to erect a suitable monument to commemorate the virtues, statesmanship and professional ability of this first American sanitarian. May we not hope the movement inaugurated yesterday for immediately raising the necessary funds will be carried to a successful issue, so that in the near future we shall see the consummation of this most desirable work? Following in the wake of this early and eminent sanitarian, zealous workers in our profession, earnest men from other walks in life filled with philanthropic desire to improve the status of their fellows, have worked together to diffuse the knowledge they have gained by careful research among the people until our whole nation is permeated with the leaven of preventable medicine—and although it has been generally conceded that the people by their representatives have the right to enact laws which will protect them as individuals or as

communities against all influences which are harmful to the person, property or health of the individual separately, or collectively as a community; yet it was nearly thirty years after the pioneers in this work attempted to improve the hygienic status of the poor in some of the manufacturing parts of the larger English towns, before the first State Board of Health was established by act of legislation in this country, that of Massachusetts.

So luminous was her example and so active, thorough and faithful in their teachings were the missionaries of this gospel of cleanliness and prevention that now every State in the Union, except three, have their Health Department established by legislative act, each of which is doing its own peculiar work, diffusing to a greater or less extent in their respective States a knowledge of personal hygiene, and exercising the powers delegated to them to prevent the spread of epidemic and contagious diseases, with the result that the citizen finds himself less liable to the contagion of pestilential disease, and with a prospect of added years to his average of life. I desire to call your attention to the great and good work these State Boards have done and to commend them for their enthusiasm, their patience and their perseverance in the varied and often delicate duties which have devolved upon them.

Not in every instance have they been composed of men familiar with the rudiments of sanitation, but too often political considerations have entered into the choice that an executive has made. This can not be too severely condemned, and an enlightened public are demanding that these boards shall be composed of experts thoroughly trained by education and experience in the best and latest sanitary knowledge, and the methods of applied hygiene. But the best of those boards have at times felt that the inadequate pecuniary provisions which have been made for work by even the most liberal Legislatures have hampered them in so many ways that the results of their labors have fallen far short of what they might and ought to have been, not alone for the sake of science itself, but for the best and highest welfare of the States themselves.

It is the part of wisdom and good statesmanship that in each State the militia should be equipped and drilled for service as conservators of domestic peace, and as a reliance for protection from a possible foreign invasion. It is interesting and stirs one's patriotism to observe with what alacrity and unanimity, legislators vote generous appropriations for these purposes. How painful the contrast when asked for a comparative pittance for carrying out measures to protect the same people from the invasion of an army of microbes which threaten more lives than the invading army of any foreign foe. My own State spending annually \$20,000 more upon its one regiment of National Guards than upon its Health De-

partment, and the great and good Commonwealth of Massachusetts, pioneer in sanitary science as she has been in so much that has been for the benefit of humanity and the advance of our higher civilization, appropriates annually \$187,000 more for maintaining her efficient military establishment than for her Board of Health. New York, the Empire State, with its large port of entry, and consequently its especial liability to invasion by any and all forms of pestilence, appropriates nearly \$800,000 more for its splendid military department than for its health organization. These will suffice as examples of all the other States. The explanation of all this is not a difficult task; it is summed up in the state of "public opinion." The masses are pleased with, and have no criticism for, expenditures made for the gay trappings, the brilliant equipments, the pomp and grand display of their martial hosts. On the other hand, this same public, while they have become so far enlightened as to believe that some provision is necessary for their protection "from the pestilence that walketh in darkness and the destruction that wasteth at noonday," yet they do not appreciate the quiet, unostentatious work which is done in the laboratory and the quiet methods used to prevent the spread of different epidemics. These State Boards have had their efforts cramped and much circumscribed, as a result of State lines and a want of coöperation with the boards of other States, and this leads us to consider the necessity and desirability of a National Board of Health presided over by a Secretary of Public Health. It seems hardly worth while to discuss in this presence either the necessity or desirability of a National Health Bureau, when we recall that upon more than one occasion this ASSOCIATION has by unanimous vote put itself on record as being most thoroughly in favor of national sanitary supervision. We know, however, that all progress and especially innovations in the habits and methods of discharging national duties, are only brought about by "agitation"; we would therefore stir up your minds and hearts on this subject, not only as an ASSOCIATION but as individual workers, believing that if you all become thoroughly aroused to the great importance of this matter and put into its agitation at home the earnest work which you do into those things that you make mount the stairs of success, we shall not be discussing the desirability of this Bureau, but shall at our next meeting be rejoicing over the accomplishment of our purpose and the fulfillment of our desire. The bill introduced by Mr. Gray into the last Congress and known as Senate Bill 1840 was, I believe a child of this ASSOCIATION; it was a good measure and ought to have become a law. But, alas! it came to an untimely death in the hands of the Committee on Epidemic Diseases. It was prepared and presented as were many other worthy measures, with enthusiastic hopes that the LIII Congress would rise to its high privilege, and embrace the great opportunities that presented themselves for beneficent and practical legislation. But those hopes were

"Like Dead Sea fruit that tempts the eye,  
But turns to ashes on the lips."

Before this bill is introduced into the LIV Congress, it would be wise, we believe, to amend it, by providing for an advisory board of one member from each State, from the Medical Corps of the Army, Navy and Marine-Hospital Service. This would render it more practical and more popular. This advisory

board would only meet on the call of the Secretary of Public Health, and would discuss and advise upon such questions as he might propose. They would be his correspondents in different parts of the country, and would be required to render such service as he might demand. In order, however, to secure the passage of any bill it will be necessary to educate the press and through them the people and their representatives in Congress. This can be best done by the members of this ASSOCIATION, each in his own State. The facts that demand attention are numerous and convincing, and it would seem that they need only to be presented to carry conviction to the mind of the ordinary person. Let the attention of congressmen be called to the records of the War Department, which show that during our Civil War the number killed in battle and of deaths from wounds was 93,443; the deaths from preventable diseases were 108,666. If to this vast number who perished, we add those who were disabled and broken in health by the infliction of preventable diseases that did not kill, as instance the 1,700,000 cases of diarrheal diseases, and we have the startling fact that no foe which could give us battle would decimate the active population of the country like the preventable diseases. At the same time, millions upon millions are appropriated, and rightly too, to give the nation a Navy that will protect us from attacks of foreign armies, but only a few paltry thousands to protect our nation from the greater scourge of preventable disease.

If we desire and expect to obtain satisfactory legislation, either by the enactment into law of this or any other bill, this ASSOCIATION should not only appoint a committee familiar with the subject and its requirements, who are able to present to the congressional committee to whom it is referred, and to other members of Congress the reason for asking and the results reasonably to be expected from such legislation, but a committee who will stand as sponsors for the bill, to see that it is not unduly delayed or entirely smothered in committee. Any one who has had any experience with legislation, knows that unless a bill is known to have behind it some responsible party, who is earnestly watching its fate, that it is very likely to be forgotten and superseded by some measure that has a friend to watch its interests. The ASSOCIATION should further show its earnestness in this matter by making an appropriation from its funds of such a sum as will pay all reasonable expense incurred.

The subjects which would present themselves for study, investigation and regulation to this National Health Bureau are so numerous that we can only call attention to a few of them. It may be true, as suggested in a recent work on degeneration by Nordau, that we are living in an age when degenerates are to the front, forming public opinion and educating the masses by a literature which emanates from the brain of a degenerate, who is so well described by this author as a person who "finds it easier and more convenient to allow his brain centers to produce semi-lucid, nebulously blurred ideas and inchoate embryonic thoughts, and to surrender himself to the perpetual obfuscation of a boundless, aimless and shoreless stream of fugitive ideas; who rarely arouses himself to the painful attempt to check or counteract the capricious and, as a rule, purely mechanical associations of ideas and succession of images, or brings under discipline the disorderly tumult of his fluid presentations. On the contrary,

he rejoices in his faculty of imagination, which he contrasts with the insipidity of the Philistines, and devotes himself with predilection to all sorts of unlicensed pursuits permitted by the unshackled vagabondage of his mind; while he can not endure well-ordered civil occupations requiring attention and constant heed to reality." If it is further true, as is claimed, that the number of these degenerates in this country are being rapidly increased in number by reason of the use of narcotics and stimulants, of tainted, adulterated or contaminated foods, the absorption of organic poisons, the sapping of vitality by the constant nervous excitement under which we live; is it not time that there should be some authoritative branch of the government, to inquire into the causes of this degeneracy and advise some means of staying the tide of national destruction?

It is certain that the safety and welfare of the people of this country, and the interests of commerce, demand the establishment of a uniform system of quarantine, under the control of the Federal Government. It has been well said that in times of danger it is of equal concern to the entire country—to the people of the interior States as well as those on the seaboard—that quarantine should be national in character. It is not just to throw the expense and responsibility of the defense upon any one class of the State, nor is it just to deprive those living in an interior State, from a voice as to the method and degree of protection along the seaboard and frontiers. Furthermore, to render all lines of defense effective, every point must be fortified when the invasion of disease is threatened or possible. Neither is it wise or safe to trust the defenses to chance or to a quarantine system varying at different points, as now exists under the separate regulations of the various States. While safety should be secured, as little interference and inconvenience with commerce and individuals should be allowed as possible.

The efficient Health Officer of Canada has well said, "that from the long period of incubation of some of the infectious diseases and the relative shortness of the voyage from many ports outside the country, and from the possibility of disease lurking in imported clothing and effects, it is evident that unless there could be a routine quarantine detention of all vessels arriving at every port and a routine disinfection of all clothing and merchandise from abroad, there is always the possibility of exotic disease passing the quarantine barriers in an invisible and unrecognizable stage and condition, and first declaring itself in the interior of the country. This can not be avoided without such detention of vessels, passengers and merchandise at the ports of arrival, and such consequent interference with trade and commerce as would be quite unjustifiable and impracticable." Hence the necessity of a central, harmonizing, governing board to bring into coöperation the various local Health Boards—and at the same time to secure the necessary coöperation of all foreign nations; in fact, the adoption, in some form, of the recommendation made at the meeting of the National Quarantine and Sanitary Association by a committee of which our venerable associate, Dr. A. N. Bell was chairman: "That of the adoption, by the commercial nations, of a sound and well-digested code of marine hygiene, and of the necessary measures for insuring its strict enforcement." While we would urge with all zeal the necessity of national quarantine, we would hold

in grateful remembrance the work of local boards in our large ports of entry, and the able and thorough efforts in this direction of the Marine-Hospital Service. But we must bear in mind that this service was rendered in default of any national organization that could do this work.

We recognize how much of our safety depends upon the thoroughness with which proper quarantine regulations are enforced by the sanitary authorities of Canada. It is a pleasure to speak with some personal knowledge of the faithful and painstaking work done in the Dominion under the watchful care of the Medical Superintendent of Canadian Quarantine Service, Dr. Frederick Montizambert. By this efficient service the danger of imported diseases from this source is infinitesimal.

Standing as we do on the verge of the centennial of the first successful demonstration of secured immunity from disease, by the use of an antitoxin, it is pertinent for us to inquire if we are, in the light of our present scientific knowledge, carrying out carefully and faithfully, vaccination, as Jenner gave it to us. It only requires the announcement that small-pox has appeared in any community, to learn how large is the number of adults who have never been vaccinated, not because of any objection to vaccination, but from neglect in having their attention called to it. Could we honor the memory of Jenner, and celebrate the discovery of this great boon he gave to the world, in a more fitting manner than by seeing to it that in all the families we enter, this royal deliverance from a most loathsome disease is placed at their disposal? It is unnecessary to discuss before this body the usefulness, the desirableness, the imperative necessity of this wonderful protection to the human family. Each year of the century has demonstrated it. Millions of people have testified to its beneficent powers. In this country, and in most of the countries on the continent, animal lymph is used in preference to humanized. England is now adopting it in some measure; but the Jennerian method of arm-to-arm vaccination has had so strong a hold that it has been slow in adopting the use of bovine lymph.

In nearly all foreign countries the production and distribution of calf lymph is under control of the government; in this country, however, only two States maintain vaccine establishments for the propagation of vaccine lymph. The general government does nothing at all. As a result we have the production and distribution of lymph in the hands of commercial men. Dr. Abbott remarks that, "the private producer conducts his operations in such a manner as to secure the greatest possible returns with the least possible outlay of money. Vaccine lymph is bought and sold, and competition in prices naturally leads to deterioration in the quality of this important article, which should be freed from every influence which may in any way lead to its impairment." But the danger lies not only in the fact that it is an article of commerce, but still more in the methods of its sale. Druggists and middlemen act as agents for its sale; as a consequence this vaccine lymph often remains for weeks or months in the drawers of these agents, and when needed for use the guarantee of the producer is disregarded, the lymph of several weeks or months ago is sold, and finally used for vaccination. As a result it proves inert, and the consequence is charged to the insusceptibility of the infant or vaccinated person.

As a matter of fact, when vaccination is conducted under the best conditions of fresh lymph, insusceptibility is found not to exist, or to be a matter of rare occurrence. If such vaccinations are being made during a brisk epidemic of smallpox, and in families which have been exposed to the disease, it may happen that some children will take the disease and die, during the delay occasioned by waiting to ascertain whether the lymph of uncertain source and age will prove successful or not, and thus life is jeopardized and the practice of vaccination falls into disrepute. Again, the commercial producer is very likely, in his haste to become rich, to take less time and to become careless in his technique—in consequence the lymph becomes contaminated with foreign microbes which may produce either abscess, septicemia, or other pathologic states. For these reasons we would urge that a most imperative demand exists for the establishment of a National Health Bureau, one duty of which would be to produce a pure vaccine lymph under the most careful aseptic conditions and furnish it to State Boards free or at cost.

It is a serious question if the time has not arrived when the medical profession should study from a purely scientific standpoint the great practical question of the effects of alcohol as a beverage.

Dr. Crothers, in an address before the Public Health Association, asserted that, "Inebriety is clearly more prominent as a cause of disease and degeneration than all other factors known at present. The various authorities who have tried to tabulate the number of defectives due directly and indirectly to inebriety, have varied widely in their estimates, showing that the facts are not yet all grouped and studied. These estimates have placed inebriety as the active cause of from 10 to 60 per cent. of all insanity; from 30 to 80 per cent. of all pauperism; from 60 to 90 per cent. of all criminality; and 30 per cent. of all idiocy. These are the highest and lowest estimates made by various authorities in this country and Europe, and bring unmistakable evidence of the influence of inebriety, not only over public health, but over all growth and civilization." Here is a subject for investigation in which our profession should, as guardians of the public health and as conservators of the country's good, take the lead, and not trail in the rear of public opinion as we are now doing. It is not only our privilege, but our duty, as members of the only profession who by training and experience are prepared to enter upon a thorough scientific study of the questions which it involves. If scientific workers in the medical profession, with the authority of this ASSOCIATION, should examine this question from a purely scientific and practical standpoint, taking facts and not theory as a basis, we should soon be in possession of accumulated knowledge which would enable the medical profession to speak with authority upon a problem which has been agitated and considered from other standpoints, without being able to lay down positive and incontrovertible propositions as to its effects, and the best means to remedy the various resultant conditions. It is true that for many years a committee of the British Medical Association have had the subject under consideration and, in connection with the British Social Science and Public Health Associations, have done much to place this question upon a scientific basis, and have furnished data from which an effort has been made to restrict and alleviate the various phases of trouble that have

resulted from its general use. Yet as diseases in general are modified or intensified and their sequelæ changed by climate and environment, in how much larger measure shall we find that the effects of alcohol are different in our climate, with our natural characteristics and the different forms or methods of using it. Let a National Bureau of Health take this matter in charge, and pursue an exhaustive investigation upon the lines indicated, calling to their aid and utilizing the work done by committees of this and other organizations, and it would soon be in possession of positive facts with which to elucidate this great problem.

At the present time the whole world is roused and stands with bated breath listening for the scientist to announce the discovery of a new therapeutic or preventative serum. It is believed that we are possessed of a serum or antitoxin by which the mortality of diphtheria is apparently very much reduced; while we are in the stage of demonstration of the effects of this serum in preventing and curing this disease, it is necessary that we should exercise great care in securing fresh reliable antitoxin, and caution in its use. In this matter we are again indebted to Massachusetts for an example of what the general government should do; prepare under suitable conditions the antitoxin of undoubted purity and supply, under proper regulations, free to such communities as might desire it. Investigating experimentation is going on in many laboratories which promises to give us other valuable curative and preventative serums. Although disappointed in the curative value of tuberculin it has proved of great value in the diagnosis of bovine tuberculosis. In the older States, where great attention has been given to dairy interests, every method has been adopted that would in any way increase the product of milk, regardless of the health of the animal; as a result, we have under these conditions what is practically unknown on the prairies of the West, a corresponding increase in diseases affecting the dairy cow, the principal one being tuberculosis.

James Law in a report on tuberculosis remarked: "Few, if any, diseases maintain a sway over a more numerous genera of animals than tuberculosis. All must, therefore, be considered as possible bearers and disseminators of the infection, and no such animal can be left out of account in any systematic attempt to root out the disease. Some are, however, justly held to contribute more than others to the maintenance of the affection and in this sense, in addition to man himself, we must consider as preëminently bearers of this disease cattle, fowls and pigs. It is doubtful if any observation or study has been sufficiently thorough to enable any one to make an accurate table of the prevalence of this disease among the cattle of this country. As already indicated it is hardly known in the West, as in over two million beeves examined in the packing centers it was present in only two-tenths of 1 per cent., while in cows in this city (Baltimore)  $2\frac{1}{2}$  to  $3\frac{1}{2}$  per cent. showed its presence, and in at least twenty thousand examined in the State of New York it was present in nearly 2 per cent. In Massachusetts it was present in 7 per cent. During the last five years various investigators have been at work upon this subject, and have arrived at conclusions more or less correct regarding some of its phases. These conclusions are of a most startling character and certainly demand and are receiving at

the hands of the profession most serious consideration; among the laity these decisions have produced a state of great alarm and an apprehension of danger from the use of dairy products as well as meat. Time will not permit us to enter upon a full discussion of this subject; we may, however, briefly consider some of the conclusions arrived at after a careful and thorough clinical study, as well as biologic experiments, post-mortem examinations and microscopic investigations of the flesh and milk of a large number of animals. Dr. P. H. Bryce, Secretary of the Provincial Board of Health, Toronto, having made a most careful study presents the following deductions:

1. That tubercular infection has existed in greater or less degree in man, according to post-mortem evidence in a percentage, in some groups of cases, to the extent of from 25 to 50 per cent.

2. That it produces fatal results at different life periods after the first year to an almost equal degree.

3. That the tubercular process, fatal in so large a degree, may nevertheless exist in man and in animals, according to the localization, condition and extent of the tubercle, the constitution of the individual, the environment, as of climate, etc., for an indefinite length of time, the individual finally dying from other disease.

4. That the infection may, however, be present in such instances to an extent sufficient to transmit the disease through the air passages, and possibly in cattle through the medium of the milk.

5. That in many cases the disease may remain in an inactive condition, the man continuing in a fair condition of health, and being able to pursue his ordinary avocation, and the cow appearing well nourished and giving milk in apparently normal quantities; but that in all such cases there is an ever present danger of cold, or other occasion of inflammation setting up general infection of the system with fatal results.

6. That the seat of the disease will largely determine the degree of danger of infection and the direction of its transmission.

7. That in cattle, while the bacilli are probably always present in the milk when the udder is tubercular, yet the bacilli may be present in the milk in a considerable percentage of cases where even post-mortem examination reveals no tubercles of the udder.

8. That in woman, tuberculosis of the mamma is but seldom found.

9. That in cases where tubercle is present in lymphatic glands, in lungs, liver and other organs, the juice of the muscles has been found in some instances to produce infection, even where no tubercle of muscular tissue could be discovered.

9a. That the inoculation of either men or cattle, when not experimental, takes place in practice always by way either of the respiratory or of the alimentary tract.

10. That such inoculation is dependent upon the extent and frequency of the passage of infective materials into either tract, and largely upon the receptive condition of the mucous membrane in both cases. A healthy mucous membrane offers much resistance to the passage of bacilli.

11. That the infection may begin in the epithelial surface of the air cells of the respiratory tract, and probably, in some instances, also in that of the mucous membrane of the intestinal tract.

12. That when bacilli pass into the system they do so by way either of the blood capillaries or of the lymphatic vessels in the walls of the air passages and the villi of the intestines.

13. That when they have passed into the blood capillaries they may produce localized tubercles at the point of inoculation, or may, by passing into the blood current, produce infection at points and in organs distant from the same.

14. That inoculation into the lymphatics, while capable of producing localized infection, tends to transmission of the bacilli to the neighboring lymphatic glands and to the prevention of the progress of tubercular infection of the system.

15. That while inoculation by means of the blood vessels of the intestines may result in tubercles in the liver, spleen, etc., yet inoculation by the chyliferous lymphatic is likely to result in tubercles localized in the lymphatic glands, especially of the intestines and mesentery.

16. That both in man and cattle, by far the most common seat of tubercles is in the lungs and adjacent lymphatic glands; and that this fact, along with the statistical evidence of the frequently repeated cases of pulmonary tuberculosis in persons exposed to the infected air of sick rooms and in cows to that of infected stables, points to the inference that the great proportion of cases of tuberculosis are the results of aerial infection by way of the respiratory tract.

17. That while the great number of deaths from tuberculosis in children, as from *tabes mesenterica* or consumption of the bowels, points to the probability of frequent cases of infection through milk and other food by way of the alimentary tract; yet the still larger number of cases of lung tuberculosis in children, the relatively small number of calves and young cattle infected with tuberculosis and the comparatively few instances of tuberculous cattle in which the intestines, mesentery or other abdominal organs are found on examination to be exclusively tubercular, point very strongly to the conclusion that infection by way of the intestines is relatively seldom in cattle, and that where it does take place in children it most probably is dependent on the previously unhealthy and congested state of the mucous membrane of the walls of the stomach and of the intestines.

After the most careful experiments, Drs. Ernst and Peters arrive at these conclusions concerning the infectiousness of milk: "First and emphatically, that the milk from cows affected with tuberculosis in any part of the body may contain the virus of the disease.

"That the virus is present whether there is disease of the udder or not.

"That there is no ground for the assertion that there must be a lesion of the udder before the milk can contain the infection of tuberculosis.

"That, on the contrary, the bacilli of tuberculosis are present, but with no discoverable udder lesions."

It will be noticed that these investigators, although working in widely different fields, have made one point in common which seems to be of great significance so far as its propagation is concerned, that is "that the juice of the muscles has been found to produce infection when no tubercle of muscular tissue was found, but when it was found in other structures of the body." The milk of cows suffering from tubercle in the lungs but without any lesion of the

udder or the presence in the milk of any bacillus, will by inoculation produce tuberculosis. This would seem to add weight to the question already raised, whether the disease is caused by the bacilli, or by a virus of which the bacillus is only an incident. The prevention and cure by anti-tubercle serum as advocated by Dr. Paul Paquin and others, if efficacious would do much to save life and prevent the destruction of property. Should further data be needed to show the important place this subject would hold in governmental investigation, it is only necessary to call attention to the commercial importance of our beef and dairy products, the market for which is now in jeopardy by reason of the exaggerated fears of people lest they gather to themselves the seeds of disease.

The subjects which would demand attention from a Department of Public Health, are exceedingly numerous. The question of proprietary medicine which interests every family in the land, is an evil which in spite of the continuous maledictions that have been hurled against it by all scientific medicine, both as organizations and as individuals, has continued to thrive, until at the present time it is intrenched behind millions of money and is held in high esteem by the people because of its ability to hide its worthless character or possible dangerous combination behind a trade-mark. If the manufacturers of these nostrums were obliged to deposit with the Public Health Department, under certain restrictions, as suggested by Dr. Stewart, the formulæ from which they are prepared, it would do more to eradicate this stupendous swindle from the land than all the fulminations that could be hurled at it for centuries; it would have an equally elevating effect upon the science of pharmacy which is so indispensable to our success.

The question of pure unadulterated foods, pure drugs, pure water; the cause and prevention of the degeneration already alluded to and the resulting increase of insanity; the effect of our varied climate upon the diseases we suffer from, and many others all press for solution, until we are ready to echo the sentiment of the Norse legend:

"Labor with what zeal we will,  
Something still remains undone,  
Something uncompleted still,  
Waits the rising of the sun.

"By the bedside, on the stair,  
At the threshold, near the gates,  
With its menace or its prayer,  
Like a mendicant it waits;

"Waits, and will not go away,—  
Waits, and will not be gainsaid.  
By the cares of yesterday  
Each to-day is heavier made,

"Till at length it is, or seems,  
Greater than our strength can bear,—  
As the burden of our dreams,  
Pressing on us everywhere;

"And we stand from day to day  
Like the dwarfs of times gone by,  
Who, as Northern legends say,  
On their shoulders held the sky."

**A Quadruple Birth.**—A case of this nature is reported from Brooklyn, in the family of a tailor named Lowenstein. The mother died with the delivery of the fourth child. Two of the four—the two first born—survived. They are males; one of these has since succumbed. The two juniors, a boy and a girl, were born dead. The combined weight of the four children was sixteen pounds.

## ADDRESS OF WELCOME,

TO THE AMERICAN MEDICAL ASSOCIATION, AT THE MEETING IN BALTIMORE, MAY 7, 1895.

BY S. C. CHEW, A.M., M.D.

BALTIMORE.

*Gentlemen of the American Medical Association:*—The medical profession of Baltimore tenders to you a most cordial and fraternal greeting. Eight and twenty years have passed since this city was last honored by your presence here, and the changes which in that time have taken place in the Association, and in the world around us, are a measure of the changes—happily advances in knowledge,—which have occurred in medical science. For though our organization has enjoyed a continuous and vigorous existence in its corporate capacity from its last sojourn here to the present time, yet it may be suspected that comparatively few of those who were then members of this body are with us to-day. Since then a whole generation of physicians has largely passed away. Another generation has come into existence, so that of those active and strenuous workers in the profession who are here to-day, many had then not entered it, and some, no doubt, were unborn.

"The old order has changed and yielded place to new."

And if such difference exists in our Association, how different, too, were our surroundings at that time. In 1866 the population of the United States was 35,000,000; now it is nearly, if not quite, 70,000,000. Baltimore, when you were last gathered here, was a city of about 250,000 souls; and now it numbers 500,000. But a more important change in its interest to our profession than mere increase of population is found in the fact that this city has become one of the chief centers of medical education in the country, and as such attracts here about a thousand medical students every year.

Again, at your former meeting here, the swell of the storm of civil conflict had not yet wholly subsided; some of its sad results were in many places still manifest and flagrant, and among them was the retardation of medical progress. For, if in the midst of arms the laws are silent, so too the voice of science is hushed or lowered. Peace is the atmosphere in which she flourishes and achieves her greatest triumphs; and in that long and blessed peace which our country has enjoyed, how great are the advances which medical science has made. And perhaps the greatest of all these advances—greater than the discoveries of specific methods of treatment, though these have been great and most important;—greater than antiseptics, and antitoxin, and the other additions to our therapeutic resources, though these have been numerous and most beneficial;—greater than the devising of operative procedures which thirty years ago were hardly dreamed of, but which have already added thousands of years to the general sum of human life;—greater than any of these, "by the all-hail hereafter," because having the "promise and potency" of results exceeding any that have yet been achieved, is the elevation of the standard of medical education and attainment, which has been effected of late years, and which is continually being raised higher and higher. For what may not be expected from the future when we consider what an increasingly large number of accurately trained minds are devoting themselves to medical work?—of minds trained thoroughly, both in those preliminary branches of science

which bear directly upon medicine, such as biology, histology, bacteriology and chemistry, and also in those which are of the very center and essence of medicine itself, such as pathology and experimental therapeutics. Many are now entering our profession every year, equipped with a knowledge of scientific methods of research and practice which not long ago were entirely or in great degree unknown.

This is what the higher medical education is accomplishing, that wherever civilization extends, medicine is prosecuted by multitudes of earnest workers in the spirit of that inductive philosophy, of which it has been finely said that: "It never rests; is never perfect. Its law is progress. A point which yesterday was invisible, is its goal to-day, and will be its starting-post to-morrow." The attainments of this present time will hereafter seem but faint beginnings in comparison with what the future will achieve. For,

"Though much is done, much more remains to do."

A broader light will surely illumine much that is now obscure. More delicate methods of examination than any we now possess, will foreshadow impending diseases, or detect them at earlier and more remediable periods of their courses. The histologic changes in which inflammations take their rise, will be more clearly made out in their very beginning, and their train of consequences arrested. The ptomaines and other poisons by which "the life of all the blood is touched corruptibly," and zymotic diseases produced, will be more thoroughly investigated, and more efficiently guarded against, neutralized or expelled. Epidemic diseases, the nature and origin of which are involved in obscurity, the pestilence that now "walketh in darkness," will be set in clear light, to be blotted from the sum of human ills forever. The great subject of neuro-pathology, now almost in its infancy, will receive immense development, not only through increased knowledge of the special functions of different portions of the brain and cord, but by the power which may then be possessed of tracing the earliest disturbances in vascular and glandular action to altered innervation. All these gains which the future may have in store, and countless others of which we do not now even dream, will be the results of the higher medical education.

And if, hereafter, those of the present day shall be regarded as

"the ancients of the earth,  
And in the morning of the times,"

yet it will be looked back upon as a morning not clouded over with the mists of error, prejudice and superstition, but bright with the promise of those good things which then will be blessed realities.

This is what the higher medical education is effecting, that every year a greater number of earnest workers are entering the profession of medicine better qualified for its labors and duties. And what are those duties? We are perfectly familiar with them, and yet, perhaps it is well from time to time to regard them steadily in order to deepen the impressions which they should make upon us. What are the great objects to which our medical science is devoted? Are they not these? First, on its practical side, briefly this,—“that they may have life, and that they may have it more abundantly.” The prolongation of life, the mitigation of the evils of life, the assuagement of the pains of life, are what it seeks to accomplish. And on its ideal side it has no other object than the search for truth,—the pure and perfect

truth. It is never concerned in making the worse appear the better reason; it admits no *stare decisis* doctrine; it is not guided in its conclusions by authority as having value in itself apart from the evidence it offers. It seeks for truth and for truth alone in the spirit of those great words, "The truth shall make you free;" words, which, as in the highest sense in which they were first spoken, so in every subordinate sphere in which truth is earnestly sought for, will be found to justify themselves. Freedom in some form is ever gained by a knowledge of truth. Freedom from the shackles of ignorance; freedom from the physical ills of pain and disease, with which human life is envired; freedom from the follies of charlatantry and false systems,—the countless *isms* and *pathies* of the day,—those "oppositions or *antitheses* of science falsely so called," from which rational medicine is separated as by the barrier that divides order from confusion, light from darkness; these are the good gifts to be imparted by a knowledge of those truths for which we, as physicians, are striving.

Gentlemen of the Association, in welcoming you here to-day it is our earnest wish that the counsels which you take together may be instrumental and effective in promoting these high objects.

## LECTURES.

### LECTURES ON INTRACRANIAL SURGERY.

XI.—THE SURGICAL TREATMENT OF INSANITY.

BY EMORY LANPHEAR, M.D., PH.D.

ST. LOUIS, MO.

Every extensive insane asylum in the world contains scores of patients whose minds might have been saved by timely and proper surgical treatment. Nor do I include in this statement those numerous cases which apparently depend upon peripheral irritation; patients who might be greatly benefited, and some perhaps cured, by the removal of irritating scar tissue, hemorrhoids, diseased uterine appendages, etc.; for in the work of such men as Robè, of Baltimore, we have seen too many instances of improvement after operation, to allow us to longer doubt the assertion that there are some insanities due to, or at least aggravated by, the long-continued irritation of peripheral nerves; even in my own limited field, I have seen mental aberration of very severe degree disappear almost as by magic under repair of lacerations of the cervix, removal of diseased ovaries, and the cure of rectal disease—hence my plea for closer physical examination of every insane patient, for the discovery of conditions which may be removed by surgical means. May be removed? Nay, *should* be, even in the face of the objections of many neurologists who violently oppose every effort of the surgeon to invade the field they have so long held sacred to themselves; and at any stage of the disease—just as soon as the local trouble is discovered. Even some asylum physicians are recently acknowledging the truth of this assertion. Thus Dr. L. A. Weatherby, Physician to Bailbrook Asylum, in an article which has been severely criticized by some psychiatrists, says: "I am myself satisfied that the surgical treatment and cure of hemorrhoids, contracted sphincters and tumors and fissures of the rectum, displacements and other diseases of the uterus often—by removing the exciting cause—brings to a happy termination many a case of melancholia and hypo-

chondriasis. Cases under my own personal observation have proved this beyond question." The followers of Pratt, in the line of official surgery, though carried to an extreme by their enthusiasm, are calling deserved attention to a kind of work that may yield good results. But, enticing as is this line of thought, it can not be considered in a lecture limited to intracranial surgery, so my remarks must be confined to insanity dependent upon trauma, tumors, softening, abscess and like affections. Nor are such cases rare, as I have intimated in my opening statement. Upon the contrary they are very common—far more so than alienists of the not remote past have led us to believe; it is one of the blots upon the pages of modern surgical history that so many cases of epilepsy and insanity have been allowed to develop subsequent to head injuries.

Upon careful search I can find little in medical literature upon the subject of trephining for insanity; and nothing that is very definite or satisfactory. Indeed, it is quite probable that nothing of great importance, save here and there the report of single cases with comments, is to be found anywhere since Weatherby in the *International Medical Annual* for 1889 says: "Surgery has so far played an exceedingly small part in the treatment of insanity; and yet we are beginning more and more to believe that surgical interference may do good in many cases of mental disease. Latterly, operation has been found to give great relief in cases where intracranial pressure was suspected, and on operation found to be present. We may well be justified in the belief that in time, as our knowledge of the localization of brain diseases becomes more definite, the use of the trephine will be a more constant factor in the treatment of some forms of insanity."

At the outset of our study of this subject it may be said that osteal and dural disease, as well as both structural and functional disturbance of the cortical and subcortical tissues, may occasion every variety and degree of mental aberration. We must, therefore, study each case that we meet, not so much with the idea of distinguishing the particular form or variety of insanity with which the patient is afflicted, as to determine the cause of the trouble and to decide what is the pathologic condition which gives rise to the morbid manifestations. For while we hope that the time may soon come when we can boldly open the cranium and correct certain abnormal conditions by means not yet discovered (and which we may not understand when found—as is true of the cure of tubercular peritonitis by simple laparotomy) we must at the present time confine our work to cases in which we are sure gross lesion exists; it would be manifestly absurd to open the skull for an insanity of toxic cause, whether of extrinsic origin or due to auto-intoxication; or to operate for a purely functional disturbance (if there be such) of the thought centers. The question, Is this case one for operation or is it not? is a most important one, and one which requires the most careful consideration, for we must bear in mind the fact that "insanity from gross lesions of the brain (tumors, new growths of all kinds, enostoses, spicules or portions of depressed bone, embolisms, hemorrhages, softening, cysticerci, etc.) is attended with the same indications as those conditions which arise from diffuse disorders of the brain; that is, giving rise to any of the symptoms of the various psycho-neuroses and cerebro-

psychoses. The lowered moral and mental tone after cerebral hemorrhages, for example, is a matter of common observation, as after one an individual is rarely observed to be himself again." (Pepper's "System of Medicine".) The necessity for a most careful investigation to discover the *cause* is at once apparent.

The classes of cases thus far subjected to operation are:

1. Traumatic.
  - a. Hemorrhage.
  - b. Abscess.
2. Organic.
  - c. Tumor.
  - d. Meningitis.
  - e. Softening.
  - f. Chronic hydrocephalus.
3. Epileptic.
4. General paresis.
5. Syphilitic.
6. Paranoiac.

1. *Traumatic Insanity*.—Mental disturbances the result of trauma may assume the form of (a), mania; (b), general affective degeneration—changes in character or moral nature; (c), general pseudo-paresis; (d), dementia. Fracture, with depression, is a very common cause of insanity, but it is not even necessary that there should be depression. Shaw ("Mental Diseases," page 130) says: "While fractures of the skull, with depression, are most likely to lead to serious mental mischief, yet even simple concussion may induce chronic, incurable insanity, or the disposition to it." Hence no blow upon the head of a person of neurotic tendency can be deemed insignificant; and trephining should be done at the time of accident if there be the slightest indication therefor. We must not follow the old pernicious doctrine that fractures of the skull should be left alone if not attended by symptoms of serious compression.

Garmany asserts that more than 50 per cent. of severe injuries to the frontal region, when untrephined end in epilepsy and insanity; so far as I can discover from the meager literature of the subject, less than 10 per cent. operated upon have a disastrous termination—so it may be said that fully 80 per cent. of cases of traumatic insanity might be prevented by appropriate treatment at the time of accident. As a parallel to my remark upon the prevention of epilepsy, I may then well observe that:

The way to cure traumatic insanity is to prevent it!

The significance of this remark is at once apparent when we consider the fact that only too oft the chance of recovery vanishes with the passing years, since late operation for traumatic insanity, like that for epilepsy, does not promise brilliant results because the persistent irritation of brain produces such organic change in the brain substance that nature is unable to effect complete regeneration after the source of irritation has been removed. The lesson is, therefore, to operate upon every case of insanity dependent upon demonstrable lesion amenable to surgical treatment at the earliest possible moment after development of the mental disturbance; and in serious injury to the skull to elevate depressed fracture, etc., at the time of accident, in order to prevent the appearance of this formidable condition.

The words of Agnew in his last paper are peculiarly appropriate at this point: "Whenever the medical profession can, in my judgment, accept the doctrine that *every depressed fracture, however small the*

depression and irrespective of pressure symptoms, is a proper subject for trephining, then will traumatic epilepsy and insanity largely disappear."

But the mere lapse of years need not prevent surgical interference in cases where there can be little doubt as to the connection between the head trouble and the insanity, for some most brilliant results have been obtained from operative measures even many years after the mind appeared totally shattered.

A case which shows what may sometimes be accomplished in the treatment of this form of insanity, even a long time after the development of the disease is as follows:

*Traumatic Insanity—Trephining After Three Years—Complete Recovery.*—P. G., was 52 years of age at the time of operation. Some four years before he came under my care he was kicked upon the forehead by a mule. There was a marked depressed fracture of the frontal bone in the median line just at the margin of the hairy scalp; but as he fell into the hands of a "conservative" surgeon who believed that a depressed fracture should not be operated upon unless profound symptoms of pressure are present he was not trephined, because he was unconscious but a few moments and very soon went about his business as if the injury were of no consequence. If a progressive modern surgeon had been called, who believed that every depressed fracture of the skull should be subjected to operation at the time of injury, however slight the depression and irrespective of pressure symptoms, the most disastrous consequences might have been averted; for very soon a most remarkable change occurred in the patient. Before the accident he was an exemplary husband, and devoted father; a strong opponent of intoxicating liquors and a Christian gentleman; noted for his integrity and excellent character. But soon it was seen that his character was totally changed—he deserted his wife and sought the companionship of prostitutes; he was so abusive to his children when at home that they fled from him in terror; he became so addicted to the use of whisky that he soon wasted his property and sunk to the level of the drunken sot, as often found in the gutter as in bed; he cursed and swore and seemed to lose all sense of manhood and decency—he was obscene, vulgar and debased. This condition continued for a period of more than three years with occasional intervals in which it was thought he was going to "reform"; finally after a long debauch suicidal and homicidal impulses became predominant, and at last the relatives consented to operation. Upon removing the depressed bone a large fragment of the vitreous plate was found projecting through the dura an inch or more into the frontal lobes. The superior longitudinal sinus was crushed and filled with organized blood clot, and much of the middle frontal convolutions showed signs of pressure but no decided degeneration. There was little shock and no meningitis following this extensive operation. A marked quietness instead of constant restlessness was the first change noticed in the mental condition; the countenance became more serene, the voice less coarse. As convalescence progressed it was found that the patient was more like his former self—he greeted his wife and children with a pleasant smile and kind words instead of scowls and curses. And when bodily health was completely restored he became his old self once more; gentle, affectionate and trustworthy. This improvement was not temporary. More than two years have elapsed, and his mental condition is as good as before the accident. He recalls the incidents of his mad career as one remembers a vivid dream, shuddering at the horrid recollection and trying to forget the terrors in the pleasant realities of the present.

Here, gentlemen, was a triumph of surgery, a human mind restored even after all hope seemed gone. It was a case which followed closely the history outlined by Spitzka ("Text-book of Insanity," page 371): "The subjects of this disorder are noticed to undergo a change of character, to exhibit a tendency to alcoholic excess, to become morally perverse, suspicious, brutal and quarrelsome and to manifest murderous and other violent impulses, occasionally associated with fits of maniacal exaltation or furor. This condition is remarkable for its long duration

and its frequent and sudden changes. As a rule, dementia terminates the history of the case."

A number of successful operations are mentioned in the *Annual of Universal Medical Sciences* for 1888, by Horsley, Price, MacDonald and Fletcher. The latter operated upon eight cases at the Indiana Hospital for the Insane. All of the insanities developed some years after the accident and all were subjected to operation a long time after the disease was manifested. In all but one, strong adhesions of the brain to the dura were liberated. All were melancholic, suicidal and profane, and four of them destructive to clothing. All were relieved. In none had the cortex undergone any decided pathologic change. Commenting upon the reports Senn observes: "When we consider that under strict antiseptic precautions trephining can now be done with hardly any risk to life, it must become apparent that in cases of insanity following fracture of the skull, this operation holds out a ray of light in otherwise hopeless cases. The success which has attended the operation thus far is sufficient to warrant further trial."

But such remarkably favorable results as those mentioned and as obtained in the case just related are not often possible long after the injury, as I have found in more than one attempt at restoration of mind in old trauma. A marked case may be briefly summarized thus:

*Traumatic Insanity—Operation—No Improvement—Death by Suicide.*—Wm. W., a young man of much promise fell and fractured his skull in the fronto-parietal region. He soon after became morose and sullen, abandoning his studious habits and deserted his refined companions. He became addicted to the excessive use of whisky, associated with gamblers and courtesans, neglected his business and family, and finally degenerated into a high-grade imbecile, typical terminal dementia—irresponsible, epileptic and sometimes maniacal; throughout markedly hysterical. After some three years of this kind of life he became my patient. I trephined him, corrected the difficulty fully, as I thought, and expected a brilliant result. Recovery from the operation was prompt and satisfactory so far as his bodily condition was concerned, but a melancholia followed and he committed suicide a few weeks after his discharge from the hospital.

Had this patient been properly treated at the time of injury this disastrous result would have been averted. More than this—I am of opinion that had I had an opportunity of operating soon after the development of the insanity, before such changes occurred in the brain as to prevent regeneration after removal of the cause, I might still have saved the life and mind of this young man. The case emphasizes the necessity for operation soon after the onset of mental symptoms, but still more strongly teaches that all injuries of the frontal region, of serious degree, imperatively demand operation at the time of accident; regardless of the teaching of the past.

Quite a number of successful results have been obtained in this city from trephining in cases of traumatic insanity of recent development, by Drs. G. W. Cale (two cases), F. J. Lutz, T. F. Prewitt and W. H. Mayfield. It is unfortunate that all cases of insanity operated upon have not been reported, giving results, whether favorable or unfavorable.

2. *Organic Dementia.*—"Organic dementia is the insanity which results from cerebral hemorrhage, embolism, thrombosis, ramollissement, tumors, hydatids, pachymeningitis and a few other affections. These cerebral diseases are not necessarily accompanied by mental alienation. Still they cause delirium or coma and certain other psychical dis-

turbances very frequently, and it is but natural the mental disorder should have the nature and often the permanency of positive insanity." (Kellogg, "Reference Hand-book of Medical Sciences," vol. iv, page 129.) These intracranial lesions produce the insanity: 1, by direct pressure on the brain convulsions; 2, as irritative lesions, in a reflex way; 3, by obstruction of blood supply; 4, by inflammation and abscess formation; 5, by non-inflammatory softening—as in embolism. Some focal diseases may act in not only one but several of these ways. The most common character of the psychical manifestations is a progressive impairment of all the mental faculties, ending in more or less complete loss of mind; in one of my cases (Wm. K., presently to be mentioned) this amounted to total and permanent idiocy. From what has been said, the necessity for early operation is obvious.

(a.) Insanity due to hemorrhage. I can find no account of any operation done for mental trouble due to cerebral hemorrhage, except the case of McBurney, of New York, who trephined and removed an irritating clot four months after the rupture of the vessel; with complete cure of the mental disease. But the excellent prospects of cure make me advise operation in every recent case of insanity following accessible meningeal or cerebral hemorrhage.

(b.) Insanity due to abscess. As a general thing abscesses of the brain are too rapid in their progress to give rise to chronic insanity; yet occasionally the diseased condition may exist for many months unsuspected or at least undetected. I believe that in every case of insanity preceded by chronic otitis media with suppuration, exposure of the favorite seat of cerebral abscess is justifiable. And where abscess is believed to be present elsewhere, exploratory trephining should be done. It will be remembered that one of my cerebral abscesses of the frontal region (Case 3, JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, April 13, 1895) was accompanied by serious affection of the mind, and that all the mental symptoms disappeared immediately after evacuation of the accumulation of pus.

(c.) Insanity due to tumor. Here the symptoms are exceedingly changeable and often chronic. At first they consist chiefly of headache, giddiness, and sleeplessness, together with irritability, restlessness, loss of self-control and hallucinations of the special senses; later, progressive failure of the mental faculties occurs, sometimes ending in total obliteration of all sense. This was typically shown in a case I operated upon, viz:

*Durhematoma (Cyst of the Arachnoid), with Insanity—Operation—Death.*—W. K., of the Indian Territory, was first seen by me Jan. 8, 1892. A satisfactory previous history was not obtainable, but it seems that he was as intelligent as other boys until about the age of 14 years, when he began to have epileptic convulsions of the right side, followed by temporary aphasia. The spasms finally became general, partaking of all the characteristics of *huit mal* including the mental deterioration. Finally, partial paralysis of the right side gradually made its appearance, accompanied by difficulty in remembering names and other nouns. As the epilepsy increased in severity this paralytic influence deepened until at last he was completely paralyzed in the right upper extremity, the use of the lower was so greatly impaired as to prevent walking, and language became totally obliterated. For a time he read the papers for a little while daily and seemed to understand much of what was said, though his intelligence was evidently greatly impaired. Finally he became so nearly imbecile as to require constant watching, particularly during violent outbreaks which were quite common and full of danger to those around; at the time of my examination his

mind was a total wreck—he was a typical idiot in his mental condition, though his face showed nothing abnormal.

Owing to the fairly clear, though not wholly satisfactory evidence, that the convulsions invariably began in the right hand, then spread until the whole body was involved, and also to the existence of the aphasia after the convulsions and before the dementia appeared, I had him sent to the hospital where I opened the skull, assisted by Drs. Krueger and Maxson. Upon cutting through the dura a cyst of the arachnoid was found, much larger than a hen's egg, lying over the speech and arm centers. This I tried to remove entire, in doing which I exerted too much pressure upon the brain, for the patient ceased breathing (although no chloroform had been given for several minutes) and only revived by long-continued artificial respiration. I hastily cut away the cyst and closed the dura; while doing the latter work another suspension of respiratory efforts was noted and again artificial respiration had to be instituted. The wound was quickly closed and dressed and the patient placed in bed as hastily as possible, when every possible means to combat shock were employed—to no avail; he died within a very short time.

Another case of insanity dependent upon tumor, I have already described under the title, "Osteoma—Operation—Recovery," in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, May 4, 1895. As I stated in my lecture on brain tumor, this disease is much more frequent than generally believed—particularly in insane patients; Clouston found brain tumor in 7 of 36 cases of organic dementia in his post-mortem work, and in 1,000 autopsies upon insane patients, taken without selection there were 28 tumors of the brain, mainly accessible. So operable cases must be comparatively frequent.

(d.) Insanity due to pachymeningitis. That certain forms of insanity are due to inflammation of the dura (and of the pia also), has been known for long, as post-mortem work has often demonstrated the fact that as a result of chronic pachymeningitis externa, the dura is frequently so adherent to the bone as to defy separation, with many fine osteophytes and sometimes bony plates of some size; while thickening of the arachnoid is quite common in some chronic forms with enlargement of the Pacchionian bodies; and adhesion of the pia to the brain is usual in parietic, syphilitic and alcoholic insanities. Quite a number of cases have recently been operated upon by opening the skull widely (2½ by 4 inches) over the frontal region, opening the dura, carefully breaking up adhesions between membranes and brain, dusting in much iodoform to keep the surfaces temporarily apart and closure of the wound in such manner as to secure primary union. Results have not yet been published.

(To be continued.)

## ORIGINAL ARTICLES.

### NEW DEPARTURES IN THERAPEUTICS.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, May 7-10, 1895.

BY JOHN H. HOLLISTER, A.M., M.D.  
CHICAGO.

The trend of medical thought in any given age and the theories then accepted are best discerned by a study of its therapeutics.

Whether the doctrines of Solidism, Fluidism or Vitalism for the time prevailed, we discover the fact not so much by the nomenclatures which men gave to diseases, as by the impress which was left upon therapeutic teachings. And it will not be difficult to determine what are the theories now entertained,

when in other days the methods of treatment now proposed shall be reviewed.

It is a noticeable fact, and it could not have been otherwise, that in the past, in all its conflicts with diseases, medicine was compelled to conduct a defensive warfare. So long as essential etiologic factors were unknown it was only possible to deal with *results*, and that, in these procedures our methods should have been largely empirical. Along such lines we must have proceeded indefinitely, had not the improved microscope and the perfected laboratory been placed at our command. By reason of these and the services they were able to render, our methods of treatment are undergoing a signal and most wonderful revolution. Discoveries are already made and methods of treatment which they suggest are so radical and give promise of such before unknown results, as to stamp the closing years of the century with the impress of a new era, from which possibly will date the renaissance of medicine.

In connection with the investigations and discoveries which have been made during the last twenty years, by reason of which therapy is permitted to assume an attitude so markedly aggressive, two methods of treatment are brought prominently to our attention which, while they revive the old theories of cellular and humoral pathology, yet each give promise of favorable results in the cure of diseases.

The older one is designated organic therapy or the therapy of substitution.

The latter, which at this date, more than any other subject, commands in both hemispheres critical study by our most accomplished thinkers, workers and writers is that of sero-therapy.

The cell theory so ably championed by Virchow has still and in the present field an able following, while Behring more than any other, leads the van in the advocacy of humoral pathology and of a special method of treatment conformable thereto.

Organo-therapy is based upon the claim that all vital activities have a cell-genesis; that cells are possessed of definite organisms and environments; that they are the basis of all functional activities; that in the animal economy through their agency definite results are accomplished, such as those of nutrition, secretion, and excretion; that they are responsible both for constructive and morphologic changes, and that when a perfect equilibrium in their activities is established, the whole economy is in perfect health.

It is asserted that the impairment of health begins with the impairment of cells; that these are affected, favorably or otherwise by their environments; that each has need of special pabulum, the withholding of which will surely cause first, impaired functional action, and later, cell degeneration and death; that remedial agents are valuable or otherwise, as they favorably or unfavorably affect the ultimate cell organisms. It is asserted in connection with this theory that cells possess an inherent defensive power and that by reason of these, there exists in the animal organism an ever-present and pervasive *vis vite*.

It is asserted that, as the result of stimulation, the cells develop those substances known as albuminates, proteids and nucleins, and that these are resistant and destructive to toxins that may be introduced into the system; that by reason of the presence or absence of these antitoxins, animals are susceptible or immune to diseases, and that in proportion as cells are irritated by reason of an offending presence they are

able, within certain limits, to eliminate an increased amount of their protective substance.

That these are the defensive weapons of warfare, and that when the leucocyte embraces the bacillus, as does the octopus its victim, it is not in the capacity of a phagocyte, but for the purpose of bringing more immediately to bear upon the intruder the deadly power of its own toxic secretion, and that thus through the vital energies of the organic cell the antitoxic agent is furnished and immunization becomes possible.

Acting upon the presumption that the cells have the elective power in the selection of their foods, similar to that which is apparent in the growth of all the tissues, it came to be believed that the elements essential to the nourishment of particular organs may be supplied, when wanting, from those existing in other like organs, and that special nutritive results can be attained by the use of various organic extracts.

Thus the views of Brown-Séquard, at the time but little regarded, have more and more gained in favor, until now this method of treatment is becoming somewhat general and will continue, until by present and future observations its real value is determined.

Some of these extracts have been used to a limited extent by your reader during the last two years, particularly the preparation of red-boned marrow, and without a detail of cases, which might here be justly cited as original work, it may be said in a word that in the treatment of some conditions, notably that of simple anemia, by the use of bone-marrow better results seem to be attained than had hitherto been accomplished with either arsenic, oil or iron.

Much is just now claimed for the substance termed nuclein, although its discovery is not new. For the study of its physiologic properties and for its use as a remedial agent we are mostly indebted to recent valuable labors and to an able advocacy, on the part of Professor Vaughan, of Ann Arbor.

In a published address of which nuclein is the subject, he says, speaking of the proteids and albuminates in the same connection: "These substances when introduced into the body of animals in certain amounts and under certain circumstances have the property of stimulating certain organs in the animals, so that those organs produce and supply to the blood an antidote to the substance introduced; the glands that manufacture these immunizing agents being mainly the spleen, the thyroid, and bone-marrow."

For nuclein thus obtained much is claimed. It is believed to pervade the intestinal canal and by its antiseptic powers, to prevent there, as well as in the tissues, premature decomposition. It has power, it is believed, to stimulate brain and nerve centers and thus energize the system when those powers are failing, furnishing a needed stimulant alike to the invalid and to the aged. It is believed to exert an antidotal influence against the toxins of diphtheria and after repeated trials by Knapp, Auld, Bleyer and others, its use is strongly recommended in the treatment of this disease. The explanation being that when by reason of the invasion of the diphtheria bacillus and when its toxins are acting as a powerful cell irritant, that then by cell reaction an increase of nuclein is developed in the blood, the antitoxin power of which

destroys the specific poison. The remedy is on trial. Its use is strongly recommended. Its value is yet to be determined. Of its production and the method of its use it is not needful now to speak. Strongly as the organic extracts are recommended, we are not over-sanguine as to the good which they may be able to accomplish. Their use constitutes one of our new departures, the warrant for which requires further demonstration.

We pass now to a second new method of treatment, namely that of sero-therapy. The series of discoveries which paved the way for its use, as now recommended, and which are well verified is of interest, whatever may be determined as to their utility.

The serum treatment is a sequence of the germ theory of disease, to the development of which a number of most important discoveries contributed. It dates primarily to the discovery of cell agency in fermentation in 1836 by Caignard; then to that of Donne a year later, of living organisms in pus; to the discovery in 1838 by Adet and Beaupertuis that all forms of putrefaction are accomplished by the agency of living microbes; then to the fact announced by Schwan that the air is largely responsible for their conveyance. It was Pollander who in 1839 demonstrated the presence of bacilli in the blood. His statements were soon confirmed by Davaine, who also found them present in the tissues. The methods of development and the methods of culture of micro-organisms were next made known.

Then came that most important announcement that specific microbes isolated by culture are capable of producing specific diseases. At this point a serious difficulty was encountered. Systemic intoxication by their toxins could be accomplished independent of and beyond the location of the germs. They might not be able to accomplish their deadly work *per se*, but they could develop and diffuse toxins which could accomplish that result.

How to deal with the different poisons of microbic origin became the question of the hour. Happily, for its solution we were not long in waiting. It matters not, for the moment, whether to Richet or to Ortaga of Tokyo, or to Behring belongs the credit of the discovery. Most important of all, in its practical bearing, is the essential fact, namely, the *germicidal power of blood serum*. It were enough for each or either of them if, with reference to this discovery, honors were even.

But to Behring alone doubtless belongs its first distinct enunciation, in what henceforth will be known as "Behring's law." His words were these, namely, "that blood and blood serum of a person which had been rendered artificially immune against a certain infectious disease may be transferred into another individual, with the effect to render the latter also immune, no matter how susceptible he is to the disease in question."

This fundamental law of artificial immunization was first enunciated by Behring and Kitasato in 1890 when they demonstrated that the blood rendered immune against anthrax, but made so by repeated inoculation with the anthrax cultures had the power of destroying tetanus toxins, and also that the germicidal power was present in the blood after it was withdrawn from the animal, and finally, that its transfusion to other animals rendered *them* immune from the disease. Thus the possibility of artificial immunization became an established fact, not only against bacilli

themselves but against their toxins when injected in solutions.

The further fact was also demonstrated that the antitoxin potency of serum might be greatly increased by repeated inoculations. Then came the question for decision, as to what the serum-potency should be, and the amount to be used permissible with safety. These important facts having been first settled, with reference to tetanus, it became at once a question whether all infective diseases might not in like manner be amenable to treatment.

To this end, Haffkin is conducting his experiments now numbered by many thousands in connection with the cholera bacillus. But with us during the last two years the paramount attention of almost all investigators has been turned to the treatment of diphtheria. The methods now being employed are too familiar to require recital here. Serum culture is now so far advanced, both in Europe and in this country, that the means for its use are fully at command. Again and again it has been demonstrated that this disease may be propagated at pleasure by cultures of the diphtheretic bacillus. The timely use of serum can more easily be made in this disease by reason of the local manifestations which surely demonstrate its presence, and afford ample time for remedial interference.

Its bacteriology and pathology were admirably set forth by Dr. Simon Flexner of this city, (Baltimore) in an address before the Alumni Association of Jefferson Medical College, and the history of its various phenomena familiar to most of us is there admirably expressed. Our literature in fact upon this subject is ample and much of it admirable.

But the question that it concerns us now to answer is this, Does the serum treatment give results so favorable as to command for it a permanent place in our therapeutics? It would be an immense labor to tabulate the statistics already published, detailing results from serum treatment.

The consensus of opinion in Germany found guarded expression four weeks ago at the Congress of Medicine in Munich. It was there stated that in Berlin in connection with its use the mortality fell from 44 to 21 per cent.; at the same time Professor Bayinsky reported 525 injected cases. The previous fatality had been 21 per cent., while under this treatment it was reduced to 18 per cent. And he also stated that in July and August last, when the supply of serum failed, the mortality rose to 51 per cent. Others had failed of such favorable results and were eminently conservative as to the benefits which they had witnessed.

The views of this body at the close of the discussion were embodied in three resolutions: 1, that its use was harmless to patients; 2, that a majority of observers had seen good results; 3, that experiments concerning immunization were not yet sufficient. With reference to their first point taken—namely—that its use is harmless, notes of warning are already sounding along the lines. The cautions of Hussman of Berlin, ought not to pass unheeded, nor the recent statements of Dr. Joseph E. Winters, at a late meeting of the Academy of Medicine, in New York, detailing his experience at the Willard Parker Hospital. They should certainly lead us to cautious and critical observation of many cases and their results, before yielding ready assent to the claims put forth, and to an unqualified indorsement of the serum

treatment of this disease. The able and candid statements of Dr. Winters are worthy of most careful consideration.

Again, the globucidal power of serum, transferred from one animal to another, and the serious results which may follow therefrom is a subject which has not as yet been sufficiently considered by serum advocates, and in this respect the first resolution of the Munich Congress affirming its harmlessness will hardly prove defensible.

Another subject not yet considered in this connection, as it yet *must be*, is that of the effects and counter-effects of *mixed infections*. The final demonstrations needful for the settlement of *this* question will call for a devotion of time and of talent transcending that of any other which in medicine or in any other department of learning is asking for the *ablest* of investigation.

I close with the consideration of one other point. Conceding that infectious diseases are developed by microorganisms, and that germicidal treatment is requisite, *if* it shall be found that the use of blood serum is injurious in its effects, and not warrantable in treatment, it yet remains to determine whether there are not other and safer means yet untried which may accomplish the desired result.

The beginning of an answer to this question may possibly be found in the discoveries of a new antiseptic agent by Professor Edinger, of Freiburg. Knowing that mucous secretion and saliva in particular was possessed of decided antiseptic properties and that thiocyanate of potassium was present in a rather considerable quantity in that secretion, he obtained by its combination with quinolin a rhodanate of methyl-pyridin. With this substance he carried on a series of experiments with special reference to its effects upon diphtheria and cholera bacilli and upon pyogenic microbes. He found that a "1 to 200 solution of this compound kills the cholera bacillus within an hour; a 1 to 1000 solution kills the diphtheria bacillus within an hour; a 3 to 200 solution kills the staphylococcus aureus within an hour. The same result is obtained by exposing during ten minutes the cholera bacillus to the action of a 1 to 200 solution of this rhodanate; the diphtheria bacillus to a 3 to 200 solution and the staphylococcus aureus to a 2 to 125 solution. To kill the same microbes in a minute, a 3 to 1000 solution is required for the cholera bacillus; a 9 to 1000 solution for the staphylococcus aureus. Cultures of the comma bacillus are prevented by a 1 to 10000; of the diphtheria bacillus by a 51 to 10000; and of the staphylococcus aureus by a 1 to 400 solution."

It is evident therefore that in this substance we have a newly discovered and powerful germicide. The discoverer states that it is not in the least caustic and has that advantage over carbolic acid; that it is not in the least poisonous and is thus free from the objection which holds against the use of bichlorid of mercury. It is quite possible that in this rhodanate we have a new antiseptic agent which may next lay special claim to public favor.

The rhodanate of quinolin is already in successful use in the treatment of gonorrhea, and as this remedy is far more potent and perfectly harmless, its value will soon be made apparent.

Such discoveries are strongly suggestive of what is yet to be revealed. Enough is already known to require the recasting of all our former literature and

to greatly modify most of our former therapeutic teaching. It becomes us to be, to the utmost, diligent in the attainment of facts, to be justly conservative in the acceptance of extreme statements, but to welcome every new departure that gives reasonable promise of rendering benefactions to mankind.

#### DISCUSSION.

DR. QUINE, of Chicago—Mr. Chairman, there are two of the new departures in therapeutics to which attention has been directed prominently by the essayists; concerning these I have had a little experience, which possibly justifies me in responding to the invitation that I have just received. In regard to the use of the extract of bone marrow, I am glad to be able to indorse unequivocally all that has been said in favor of it, in connection with ordinary anemia, or chloralanemia, or even in the treatment of apparent cases of progressive pernicious anemia. An example has come under my observation, and indeed it has been reported, of splenic leukemia, in which the persistent administration of bone marrow, extending over a period of several months, had the effect of increasing the number of red blood corpuscles to the extent of 17 per cent. and the hemoglobin to the extent of 8 per cent., but notwithstanding this excess effect upon the red blood corpuscles, the multiplication of white corpuscles went on with still greater rapidity, so that the total volume of blood was greatly increased by reason of the multiplication of its organized constituents. I have had but little experience in the use of diphtheria antitoxin, but enough to enable me to say that I have witnessed some deleterious effects produced by that agent. I have witnessed examples of extraordinary eruptions on the skin, and a bloody and somewhat intractable albuminuria, which finally eventuated in recovery, but I have also witnessed very striking cures of threatened laryngeal diphtheria and threatened nasal diphtheria, as a result of two or three hypodermic injections of the antitoxin under circumstances in which it appeared certain, humanly speaking, that death would have occurred within a period of twenty-four or forty-eight hours if a remedy of this kind had not been at hand. Physicians of experience have witnessed infants struggling for their breath, and already cyanotic, under circumstances in which immediate resort would be had to tracheotomy, have administered a dose or two of the antitoxin, and next morning, in visiting the house of the patient, have peeped around the corner to see if there was crape on the door, and on entering have found the patient breathing freely and easily, and crying in a natural tone of voice. Under such circumstances a physician feels warranted in speaking very loudly in favor of the continued employment of this remedy, even if experience has shown that it is a "gift horse" whose merits need to be very closely inspected.

DR. SUMMERS, of New York—I have been for the past nine months almost exclusively experimenting on the subject of nuclein. At the Board of Health we have had some extended experiments, comparing it with antitoxin. I have a paper upon that subject which I propose to offer, but Dr. Hollister has largely "stolen my thunder." I have engaged also for this Section one of the most experienced microphotographers in the city of New York, to exhibit upon a screen the effect of leukocytosis, at some hour which your Chairman will appoint, and I have also an exhibit showing the direct action of this under the microscope. I shall not take any of your time in further discussion, but in the paper which I shall present, following the trend of Dr. Hollister's remarks, all of this will be elaborated.

DR. TURCK, of Chicago—Since the experiments of Dr. Vaughan, who demonstrated that beyond doubt the toxic effects are carried by the blood throughout the whole system, I have been led in my line, the stomach and intestines, to determine the effect of nuclein in those cases of auto-intoxication from the gastro-intestinal tract. Whether in fever, or in chronic gastro-intestinal diseases, the most marked symptom is the toxic effect. Whether it be the excitement which produces that nervous irritability known as neurosis and neurasthenia, or the depressed state leading to melancholia, we know that these are the results of the toxins of microorganisms growing upon the walls of the gastro-intestinal tract. We can not reach the intestines directly, but the experiments that I have made with these cases, combining local treatment upon the stomach, the dietetics and the treatment of the colon with the administration of nucleins has had a marked effect against these toxins that are produced in the gastro-intestinal tract. Especially in cases of excitement, the vasomotor changes in

which we have sometimes agrophobia, the fear of space, seemed to go hand in hand in improving, with the improvement in these symptoms.

It is a great addition to our knowledge that these symptoms are the result of toxins due to the developing and growing microorganisms on the wall of the gastro-intestinal tract, and that the nucleins have an antitoxic effect.

### CALOMEL.

#### A STUDY OF ITS PHYSIOLOGIC ACTION AND THERAPY IN GASTRO-INTESTINAL DISORDERS IN ONE HUNDRED AND FORTY-FOUR CASES—IS IT A DIURETIC PER SE?

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY W. BLAIR STEWART, A.M., M.D.

ATLANTIC CITY, N. J.

LECTURER ON THERAPEUTICS IN THE MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA.

The physical properties of calomel are so well known to the profession that they need little consideration here. One point presents itself at this time and that is, Do you examine into the purity and quality of the calomel you use, or do you accept it as perfectly pure? Have you ever stopped to ask yourself the question why your large doses of calomel always caused griping and pain in the majority of cases?

Calomel is subject to adulteration; to improper purification in manufacture; and to chemic changes both atmospheric and in chemic mixtures. Bichlorid of mercury is the most common impurity found in it, and this varies from the smallest trace to comparatively large amounts. Many instances are on record where the usual large doses of calomel have produced violent griping, cramps and gastro-intestinal catarrh which were undoubtedly caused by the presence of bichlorid of mercury rather than "a special idiosyncrasy." In fact, instances of fatality are reported from the administration of large doses of calomel contaminated with this poison.<sup>1</sup>

On the other hand, calomel may contain such large amounts of barium, calcium, lead and other impurities that its action is greatly lessened and rendered almost inert. With these thoughts before us, and a thorough knowledge of making appropriate chemic tests for their confirmation, we can often explain many untoward actions which might otherwise be attributed to a pure preparation.

The methods of administering calomel have undergone a great change during the past ten years, and its general and special applications have been carefully studied and extended. It is an axiomatic fact that calomel should never be administered with acids or chlorids, and not at a time when the stomach is performing its digestive functions, owing to the danger of chemic change from the mild chlorid into the bichlorid, thus giving the effects of the latter drug. Until recent years, calomel has been administered in its purity, or in combination with other drugs, in doses varying from one to forty grains and in many cases the patient was an innocent victim to an overdose. To-day, calomel should be thoroughly triturated with sugar of milk and administered in doses of one-half to five grains. Why this change?

Calomel plain is a heavy drug; is very slowly assimilated and absorbed, owing to its extreme insolubility and the size of its isolated crystals. In this form it is not in its finest state of subdivision, and

is confined to a smaller area of distribution over the tissues of the alimentary tract. Calomel, when thoroughly triturated with sugar of milk, is brought into its finest state of subdivision and its presence can be readily demonstrated with the ammonia test in a trituration of 1 part in 1000, thus demonstrating the possibility of administering it in such small doses if desired. One grain of triturated calomel is capable of distribution over a wider area than the pure drug alone; is in a finer state of subdivision; is much more readily brought into a condition for absorption.

With a view of demonstrating the value of the pure drug and its trituration, I selected a number of cases in which both preparations were used at different times in the same subject, and under circumstances as nearly similar as possible. The dose selected was one grain of the pure drug and a one grain trituration with sugar of milk. The dose was administered at bedtime. In the majority of the cases where the pure calomel was given there was no evidence of a bilious stool until the next evening, and in many of them there was no apparent action at all. These same individuals some days or weeks later responded so violently to a one grain trituration that next morning one to five bilious stools resulted; and in one, who had not responded readily to the one grain pure, there was such a large number of evacuations produced that measures had to be used to check the bowels. This may be considered a mere matter of coincidence, but my clinical experience teaches me that one grain of thoroughly triturated calomel is worth an equivalent of five to ten grains of the untrituated drug. A simple mixture of calomel and sugar of milk will not produce any better results than the pure drug alone.

When given for its purgative effect, or for its action upon the liver, it is my custom to administer a one-tenth grain trituration every hour or half hour until free evacuation occurs or until one grain is taken; when, if necessary, liquor magnesii citratis is given in one ounce doses until free action is obtained. During the last four years of practice I have not found occasion to use more than one grain of the drug in the same individual for this purpose. A one-tenth grain trituration at bedtime will produce excellent results in small children, except in those who are habitually constipated, when the former method must be used. There is a certain amount of propriety in administering calomel with bicarbonate of soda, as it will prevent the formation of bichlorid and, as calomel is most readily absorbed in an alkaline medium it is synergic.

After administering calomel in a large number of cases and carefully noting the results upon the various organs, I have failed to appreciate the so-called diuretic effects of the drug *per se*. It undoubtedly acts *indirectly* to a slight extent, simply by its general stimulating action upon the emunctories of the entire body thus favoring secretion, excretion, and the elimination of intestinal ptomaines and systemic poisons, all of which act unfavorably upon the secretory and excretory organs when present. In a case of scarlatinal nephritis in a little girl of six years, with decreased amount of urine, calomel in both large and small doses produced no appreciable diuretic effects while the ordinary diuretics acted nicely. A man of sixty-five, showing mitral disease, chronic Bright's disease and edema of the lower extremities would not manifest diuretic effects from large doses of

<sup>1</sup> U. S. Dispensatory, 17 Edt., pp. 695.

calomel frequently repeated, but responded to alkaline diuretics readily. In giving the drug to over one hundred children, in varied doses, I have never noted diuretic effects which could be ascribed to it alone.

Dr. Wm. Pepper has recently reported<sup>2</sup> a case of Bright's, complicating aortic disease, where large doses of calomel were followed by diuretic effects, and where there were manifested no toxic symptoms from its prolonged use in doses of ten grains daily. His experience does not seem to point to its general diuretic action except in large doses, and then it is often uncertain in its effects. While I am still closely observing results in its use, yet I am not convinced that any diuretic action other than a very indirect one is produced by calomel. Typical biliary stools have almost invariably followed the use of the triturated preparation in doses exceeding one-quarter to one-half grain. In some cases there was a regurgitation of bile from the duodenum into the stomach, producing obstinate vomiting. Calomel undoubtedly increases the secretion and excretion of bile by its direct stimulating action upon the cells of the liver. To this cholagogue action is partially if not wholly due its beneficial results in treating diarrheas.

How does calomel act in diarrheas? When taken into the stomach in large doses it is slightly irritating; part of it is absorbed and the remainder enters the intestines where it is further absorbed and possibly may have a slight local antiseptic action. Systematically it acts upon the liver producing increased flow of bile, which enters the duodenum. Bile is nature's antiseptic and acts in neutralizing ptomaines, preventing germ growth, sometimes destroying germs themselves and aiding digestion. It increases peristaltic action and intestinal secretions and thus assists nature in cleansing the bowels by production of free biliary stools. The cause once removed, the cure is apparent. Small doses of calomel act more by a direct cellular impression, by which the cells of the stomach and bowels are stimulated to renewed physiologic activity. The action upon the liver is the same as in large doses, being proportioned to the size of the dose.

I desire briefly to report the results of treatment in one hundred and forty-four cases of all forms of diarrheas which I have noted in my work, all of which terminated successfully under the action of calomel alone and in combination. Seventeen cases in adults, all of which were due to the ingestion of improper food. Diarrhea varied from a mild to a very profuse type. Twelve powders were made from one grain of triturated calomel and one-half grain of podophyllin and one powder given every two hours until free bilious stools were produced. From two to six powders usually gave a curative result—dietetic measures being observed, as in all the cases here reported. No astringents or other medication was necessary.

Nine cases of the so-called bilious diarrhoea in adults responded rapidly to one-quarter grain triturate of calomel every four hours for two to four doses. Only one of these cases proved obstinate and it rapidly reacted to one grain doses of sulpho-carbolate of zinc every hour for six doses.

Sixty-eight cases in children from two months to ten years all received a saline cathartic of liquor magnesii citratis as preliminary treatment. This was followed by a trituration containing one one-hundredth of a

grain each of calomel and powdered ipecacuanha every one to four hours. The action of this combination in controlling the nausea and diarrhea in these cases was marvelous. The saline was often sufficient in other cases, but in those where it was not, the small doses of calomel and ipecac worked excellently. I have seen some cases so obstinate that all other forms of treatment failed, but the institution of this method, combined with strict dietetic and hygienic measures, brought about cures. It also gives me best results in treating adults suffering with diarrhea, nausea, vomiting, cholera morbus, dysentery, and the diarrhea of typhoid fever. One case of slight but obstinate dysentery in an old man of seventy-five years failed to respond to ordinary methods, but quickly subsided under this small dose of calomel and ipecac every two hours.

Twenty-five cases of obstinate diarrhea which had been running some days before consultation, all responded rapidly to a combination containing one-tenth grain of calomel and one grain each of lactopeptin and sulpho-carbolate of zinc given every two to four hours. Four cases of the diarrhea of typhoid fever responded rapidly to this same combination given every four hours.

I have met with twenty cases of diarrhea following excessive use of alcoholic liquors, and in every case have succeeded in getting absolute results in one to three days by administering a combination of one-fiftieth of a grain of calomel and one-hundredth of a grain of podophyllin every three or four hours as required. Two to four doses answered in several, while others proved rather obstinate but responded in the end.

In summarizing the results in these one hundred and forty-four cases, I am not presenting entirely new facts to you, but merely adding clinical testimony to the true efficiency of calomel and its eliminative power as contrasted with the evil routine methods of astringency and opium in treating diarrheas. These cases are not selective, but followed each other in succession. It is my general experience that diarrheas will respond more rapidly to doses varying from one-tenth to one-hundredth of a grain of calomel, thoroughly triturated, than to larger amounts. While these small doses may seem homeopathic to many they are not presented as such, but are given with a full knowledge that they will give certain clinical results which can not be obtained from larger amounts.

#### DISCUSSION.

DR. CHAPMAN, of Louisville, Ky.—I would like to ask Dr. Stewart if I understood him correctly; that is, if he considers calomel, in these small doses, one-tenth of a grain to one-fifth of a grain, as a germicide.

DR. STEWART—For the information of the Association I would be glad to answer it. I do not consider that calomel in this amount will act directly as a germicide, being entirely too small in amount. I am a believer, as I stated in the paper, that the small doses act more by a direct stimulating action upon the cells of the gastro-intestinal tract.

DR. DIDAMA, of Syracuse, N. Y.—May I also ask a question? Is it not possible, also that these doses are converted into bichlorid? Many of us have been treating these things with small doses of bichlorid every two or three hours with wonderful effects, such as the Doctor had with one-tenth grain of calomel. The large doses of calomel we would expect to have more effect than small doses.

DR. HARE, of Philadelphia—There are one or two points in the Doctor's paper which interested me. I think that the clinical results which the Doctor has had in the administration of calomel are just such results as we have all had. His paper is simply an interesting contribution confirming the experience of other physicians, summing up their experi-

ence. There are one or two statements which he made in the beginning of his paper which interested me, and I ask the following questions, not with the idea of criticising, but of being instructed. He stated that there was a possibility of a certain amount of the mercury being converted into the bichlorid of mercury. The results of my studies upon this question I have given in the columns of the *Therapeutic Gazette*. The laboratory investigations which I have made have established beyond peradventure that calomel is not converted into bichlorid of mercury. There is only two-tenths of 1 per cent. of hydrochloric acid in calomel, and it has been proved beyond all cavil that the amount which is changed into bichlorid is infinitesimal. On the other hand, clinical evidence would seem to prove that it is converted into bichlorid, because every investigation of very much note that has been made has proved, at least in the lower animals, that calomel is absolutely without effect in producing a flow of bile, but hydrochloric acid does produce a flow of bile. The question as to how calomel does act, whether it is changed by the alkaline juice of the intestine, or whether it acts as calomel or as mercury is unsettled.

The statement I am interested in is the statement of the Doctor that calomel is "adulterated" by bichlorid. I do not suppose he meant that bichlorid was employed as an adulterant. A very able chemist of Philadelphia, in the last few months, has carried out for me a series of studies in this matter. In no instance was he able to find that there was any contamination owing to the presence of bichlorid of mercury. We might have some oxid of calomel, but there was no single instance in which bichlorid of mercury was found, and I was particularly on the heels of bichlorid of mercury, because I wanted to find out whether it was the bichlorid of mercury which contaminated the mercury, or whether it was the calomel which produced the bilious stools in administering the drug.

DR. STEWART.—In answer to the first question that was asked, Is it not possible that the bichlorid was the drug which produced the results and not the calomel, I think in my paper I stated clearly that all that was theoretical. Together might be grouped the question, both of the gentleman who preceded Dr. Hare and that of Dr. Hare himself. My own belief is just as Dr. Hare has said, that there is very little of the calomel itself converted into the bichlorid in the stomach. That is all theoretical. Now comes up a question. Is there a difference between a chemic reaction conducted in the laboratory and that conducted in the stomach itself without outside interference? That is, is not a strict chemic reaction in all probability slightly different from that which is produced by what might be termed a chemico-physiologic action in the stomach? It is well known that if we interfere with the nervous supplies of any part we will have one of two results, namely, over-activity of that part or decreased activity of that part, and it is my own belief that in interfering with the stomach by operations, we interfere more or less with the active secretion of the stomach. Clinically, when I give calomel to my patients in one-tenth of a grain I do get the bilious stools. I can not say that the action comes from the calomel or the bichlorid; it may be one, it may be both, it may be either. In regard to Dr. Hare's other point, namely, in regard to the possibility of contamination of these different products by the bichlorid; my experience in the examination of these preparations has been different from those of the gentleman whom Dr. Hare quoted. I have found bichlorid present in calomel, due either to the improper drug being used or insufficient care being taken in manufacture, or else due to chemic change occurring afterward. I am not quite certain as to the authority quoted in a late number of the United States Dispensatory, in which facts are given which show us that calomel is subject to the presence of large quantities of bichlorid of mercury, and where one case is reported and the authority given for it where poisonous effects were presumed to occur from the use of calomel. This whole matter of the action of calomel in the gastrointestinal canal is theoretical.

## SOME POINTS IN THE ETIOLOGY OF PULMONARY TUBERCULOSIS.

Read in the Section on Practice of Medicine at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore, Md., May 7-10, 1895.

BY FRANK S. PARSONS, M.D.

EDITOR OF THE TIMES AND REGISTER, PHILADELPHIA, PA.

In considering the subject of pulmonary tuberculosis, and in endeavoring to support a theory deduced

from etiologic facts, which tends to show that the almost universally accepted germ cause of this disease is quite secondary in its influence, it must be admitted that, while it is evident to my mind the ground taken is not irrelevant, much opposition is to be expected.

Most physicians recognize, in certain individuals, a pre-tubercular condition; meaning by this term that in such persons who subsequently develop tuberculosis an abnormal condition exists, which, while symptomatic or suggestive of consumption, does not give that evidence of the disease which renders the diagnosis absolute; *i. e.*, the demonstration of tubercle bacilli.

It can not be denied that the tubercle bacillus plays an important part in the phenomenal expression, if not in the etiology of tuberculosis, but facts are daily being brought to light which tend to prove that the bacillus alone is as inefficient as a grain of wheat is ungerminative without sunlight, air and moisture.

When one considers the impunity with which colonies of tubercle bacilli are probably taken into the system of the majority of persons, we must fall back on the certainty of a preëxisting condition, which, when present, offers favorable influence for the development of the bacilli, on which the latter depend for support, and without which the germ is rendered inert, even though it may exist in the blood.

Hardly an autopsy is made wherein it is not seen that some time during the life of the subject, tubercles had been present in the lung, or in other tissues of the body, which tubercles had resolved or had been discharged as evidenced by cicatricial repair. We know to obtain cicatricial repair of lung tissue a suppurative process must have coexisted, and that suppuration never takes place where there is not interference with, or stasis of the circulation of a part involved. In other words, there is a loss of normal correlation between the supply of arterial blood, carrying oxygen and nutrition to the part, and the venous blood, bearing away the carbonic acid gas and waste tissue elements.

Essentially, then, perfect tissue repair is one with perfect circulation, and conversely, any stasis to the circulation prevents perfect repair. Any suppurative action must have origin in an obstruction to circulation in the part affected, and resolution, occurring during any stage, depends on the reëstablishing of normal correlation in the entire circulation of such diseased tissue. Abscess formation is nature's way of ridding tissues of abnormal waste when the circulation is impeded.

Circulation in the animal system is a complex phenomenon, physiologically of two kinds: afferent and efferent; anatomically of three kinds: arterial, which is superabundantly generous for nutrition; venous, which is inadequate for the removal of all the excess; lymphatic, which supplements the office of the veins in removing waste. A vigorously active lymphatic system precludes danger from tissue stasis in rapidly wasting parts, while inactivity of the system implies obstruction.

We may logically distinguish the lacteals and lymphatics as belonging to different systems. It is true that both character of vessels hold pabulum, a fact which does not argue against the lymphatic as being a system, the office of which is purely emunctory; for the pabulum found in these vessels, that is

not excreta in the strict sense, is so in significance being an excess of nutritional material which would speedily assume the form of an irritant were it not removed to a new situation as implied in its restoration to the general circulation.

The lymphatic system, excluded from the lacteals being accepted as primal emunctory organs, it must follow that glands like the pancreas, liver, kidneys, etc., must be considered as secondary or excremental emunctories.

Tubercle is first met with where lymphoma or lymphangitis has altered the correlative relations of the lymphatic system, and its meaning is that obstruction exists.

It is to be argued that, primarily, tubercle is a thing having no objective nature and it can be similarly said of the tubercle bacillus. Tubercle not being an objective must be a subjective condition, the subjective lying primarily with a perversion of the lymphatic system.

We may now also see how default in lymphatic action is the starting point out of which may arise many phenomena of disease, and that tuberculosis is in reality not a disease but a symptom—a symptom of lymphatic disturbance or stasis. This fact is proved by the analogy between lymphoma or surgical tuberculosis and phthisis or tuberculosis of the lungs.

What, then, is the cause of lymphatic stasis leading to a condition which may result in tuberculosis?

We know that an irritation acutely expressed, as in the case of burns, induces active inflammation. We also know that irritation of a mild degree, applied continuously, induces chronic inflammation, as in the case of gastric catarrh from the alcoholic habit. We have seen how irritation, increasing the flow of blood to a part, tends to cause hypertrophy of that part; yet, that so long as the efferent vessels carry off the additional waste there is no tendency to ulceration, or retrograde tissue metamorphoses, other than that induced by the contraction of new tissue formation, and the secondary cutting off of the blood supply. But as soon as the correlation between the efferent and afferent vessels becomes interfered with, and the waste products are left in the part, ulcerative and suppurative changes take place.

The direct cause of lymphatic stasis may lie in an excessive amount of waste material in the blood, choking up lymphatic circulation. These waste elements may differ in character and only act as local irritants from the fact that they are in an incompetent position in the circulation for nutrition, as evidenced by the attempt nature makes to excrete them.

It is a fact that in phthisis the venous blood is brighter than normal. This gives evidence that oxygen imbibed by the red blood corpuscles in the lungs is not properly oxidized in the tissues, and passes over through the capillaries in a free state. We know that the blood contains phosphorus in an oxidizable form, and that oxygen has a great chemie affinity for phosphorus; hence it is not out of reason to infer that, in this disease there is a deficiency in oxidizable phosphorus. This statement is borne out by the results of phosphorus feeding to phthisical persons, when the venous blood soon assumes its naturally darkened hue.

It is on complete oxidation in the blood that the healthy cellular life of the animal depends. Deoxidation means death. Life is opposed to death, and

nature is continually striving to preserve the former by preventing deoxidation and ridding herself of such animal cells as have become deoxidized. As soon as deoxidation in a cell takes place, that cell becomes devitalized, and is crowded out of its relation with living cells. If it can pass out through the excrementory channels, as nature intended it should, no harm will result, even if many bacteria are feasting on the defunct cell. If it can not pass out, but is held by stasis, or obstruction, or overcrowding, in its relation with other cells which have become devitalized we soon have a collection of dead material causing irritation to the nerve elements of surrounding tissue, and inflammation results.

I incline to the opinion that we have: 1, a stasis of waste elements in the lymphatics; 2, a nerve cell paralysis due to the stasis; 3, increased blood supply to the part as a result of the paralysis, and which, owing to the existing obstruction, brings about the phenomenon inflammation. All this is prior to the introduction of a tubercle bacillus.

When the tubercle bacillus enters the system of a person presenting a favorable cultivation ground for its development (which cultivation ground may be recognized in a lymphatic stasis) the attack is directed only to devitalized cells. Of this point we may feel quite certain, inasmuch as oxygen destroys the bacillus, and a thoroughly oxygenized blood cell will resist the attacks of bacilli. Bacteria, when no obstruction to waste elements exists, pass out of the body through the various emunctory organs. Their products of toxins and toxalbumins are likewise eliminated without harm to the individual. Animal experimentation, for the production of tuberculosis by injections, I feel, is of little value, inasmuch as only such animals are affected by injections as would develop lymphatic stasis from any sort of irritation mechanically applied, and the cultivation ground is at once presented.

It must be rationally argued that the favorable medium for one kind of bacillus may not be identical with that of another and, hence, various forms of germs may appear in different diseases, not because the germs are specific, except as diagnostic phenomena, but because they develop and multiply in different media.

It is to be assumed that a cause for lymphatic obstruction may be found in an incompetent excrementory organ, which theory is perfectly in accord with the acknowledgment of the lymphatic origin of tuberculosis. Such organ may be the seat of congenital or acquired incompetency; hence our cases giving family histories of phthisis.

Acquired consumption may arise from a pneumonia, the frequent "taking of colds," a bronchial catarrh and other respiratory disorders in which the lymphatic circulation of lung tissue is obstructed to a greater or less extent, and the blood cells devitalized. Cure depends on the restoration of eliminative function in these lymphatics and in building up the general system by restoration of impaired oxidation.

The question whether pulmonary tuberculosis may be communicated by contagion, or infection, does not rest with the proving that a specific germ is found in this disease, for we must know that unless a favorable medium is presented such germ will not develop, and that to obtain this medium there must be a previous condition to be recognized as pathological.

The conclusions regarding the etiology of pulmonary tuberculosis which I have endeavored to show in so brief a paper may be summed up as follows:

1. Pulmonary tuberculosis should be considered as primarily due to a lymphatic stasis, of congenital or acquired variety, depending on incompetency of excretory function, and deoxidation of blood cells.

2. That the tubercle bacillus should be regarded as a phenomenal expression of the disease, only because a favorable medium exists in the lymphatic stasis for its cultivation, and, hence, symptomatic rather than etiological. Its development is often some length of time after the stasis is apparent, as evidenced by the so-called scrofulous condition existing in most phthisical persons.

The great danger in considering the etiology of pulmonary tuberculosis lies in the fact that we are too prone to lose sight of the chemic composition of man, and the fact that disease is but a chemic decomposition, in the universal furor after a specific germ, the phenomena of which may be observed in various media in and outside the body.

#### A REPORT OF THIRTY-FOUR CASES OF PULMONARY TUBERCULOSIS TREATED BY THE METHOD OF CARASSO OF GENOA.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY DELANCY ROCHESTER, M.D.

ADJUNCT PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND CLINICAL LECTURER ON PHYSICAL DIAGNOSIS, MEDICAL DEPARTMENT OF THE UNIVERSITY OF BUFFALO; ASSISTANT VISITING PHYSICIAN BUFFALO GENERAL HOSPITAL; VISITING PHYSICIAN ERIE COUNTY HOSPITAL.

In the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for Sept. 1, 1894, is a selection from the *Cent. f. Bakter u. Parasitenk.*, by Carasso, of Genoa, in which occurs the following: "The author believes that *Mentha* exerts a direct bactericidal action upon the bacilli in the respiratory tract and that, by absorption into the circulation, it acts as a general disinfectant. Creasote acts beneficially in pulmonary tuberculosis by increasing the appetite and favoring nutrition. It also possesses some action on the secondary inflammatory exudates, favoring their absorption." Carasso's method of treatment in detail is as follows: a piece of linen cloth, ten centimeters square is folded to make a pad, five centimeters by two centimeters. By means of tape this pad is secured in contact with the nostrils. The pad is to be worn day and night and only to be removed at meal times. It is to be moistened with five or six drops of peppermint essence four or five times a day. The nostrils are to be greased with vaselin for the first few days to prevent irritation. The patient is instructed to take eight or ten deep inspirations with closed mouth; retaining the air as long as possible. After ten or fifteen minutes rest this procedure is repeated, and so on through the day.

The following mixture is given internally:

Pure beechwood creasote.....	8.
Alcohol .....	.550.
Glycerin .....	.250.
Chloroform .....	20.
Essentiæ <i>Menthæ pip</i> .....	8.

A teaspoonful every three hours in a half glassful of water. In certain cases the mixture may be further diluted with sweetened water, or the dose

may be reduced. The nutrition is favored by the method of overfeeding. Two or three liters of sterilized or boiled milk are given daily; together with plenty of meat cooked to taste; and with the addition of 400 or 500 grams of good wine.

All hygienic precautions are to be observed. The patients are instructed to carefully disinfect their expectoration, thus preventing re-infection.

The remarkable feature of Carasso's communication is the clinical report of the cases subjected to this treatment. In all cases the physical diagnosis was confirmed by finding the tubercle bacilli in the sputum. Many of the cases were well advanced in the disease, though no record is made of cases in which the lung destruction had advanced to the formation of cavities, recognizable by physical examination. In all, forty-four cases are reported. Of these there were six deaths and thirty-eight recoveries. The average duration of the treatment in these cases was sixty days. The recovery in all the recorded cases seems to have been permanent.

Although there are some points in his treatment which seem to me unphysiological and contrary to reason, nevertheless in view of the remarkable percentage of recoveries reported, I decided to give the method as fair a trial as I could and to report the result. I was the more readily inclined to such action because I have had the best results among the cases of pulmonary tuberculosis that I have treated in those in which has been combined the inhalation of menthol in petroleum oil and the internal use of increasing doses of creasote.

On Oct. 1, 1894, I took charge of the "consumption ward" of the Erie County Hospital. In the male ward there were at the time thirty-four cases of pulmonary tuberculosis in all stages of the disease. Most of them, however, further advanced than those reported by Carasso. In all but six cases, cavity could be demonstrated by physical signs. In four of these six there was infiltration of the upper lobe of the right lung; in two of the left. In all of these six the process was active and there was rise of temperature in the afternoon of a mild degree.

When I came on duty all of the patients were taking pure cod-liver oil, some of them whisky in addition to the oil, and two of the six mentioned above were taking gaining doses of creasote. No inhalations of any sort were in use. The two patients who were taking the increasing doses of creasote were gaining slowly in weight and had been doing so for three weeks previous to my taking charge.

I placed all thirty-four cases on the treatment outlined above, except that no wine was given. In some of the cases which seemed to require stimulation, whisky was used.

I intended to keep up the treatment for three months, but I have to report the melancholy result that at the end of two months all of the cases were doing so badly that I had to stop the treatment entirely or modify it markedly.

It is interesting to note that the two cases which were improving on the increasing doses of creasote continued to improve for a week, *i. e.*, continued to gain in weight but by the second week they were losing with the rest and continued to lose as long as they remained on the Carasso treatment. They both began to change so rapidly for the worse that at the end of one month I returned to their former mode of treatment, keeping up, however, the peppermint in-

halations. After the return to the creasote treatment these two cases began to improve again, and when I went off duty Jan. 1, 1895, they had gained, one four pounds and the other five. All of the thirty-four patients complained of the gastric distress occasioned by the medicine; several of them were forced to actual vomiting. One patient complained that the inhalation pad interfered with his breathing, even to the point of distress, so that we were forced to substitute deep inhalations three or four times daily without the constant use of the pad. The other thirty-three all spoke of the greater ease with which they breathed and the less frequent attacks of coughing. The sputum was not materially diminished in amount in any case, but the coughing spells were diminished in number. In the light of the result in these cases, let us review the treatment suggested.

In the first place, the inhalation of the peppermint seems to have a decidedly beneficial effect in relieving and improving the character of the cough. If continued for a sufficient length of time I do not doubt that it would change the character of the sputum and probably lessen the amount of the sputum. As to the rest of the treatment, let us examine it critically, especially in the light of the gastric disturbance that it caused in all of the thirty-four cases that I had under observation.

The directions are; 2 or 3 liters of sterilized or boiled milk are given daily, together with plenty of meat cooked to taste. The medicine is given every three hours in a half glass of water, *i. e.*, in about 125 c. c. If given every three hours in the twenty-four, that would be eight doses, but the sleep of the patients was not disturbed and they received generally six doses in the twenty-four hours, none being given between 9 P.M. and 6 A.M. Thus you see there will be given to the patient in the twenty-four hours, especially if the 400 or 500 c. c. of wine is also taken, from 3,250 to 4,250 c. c. of fluid, that means about a pint of fluid every three hours between 6 A.M. and 9 P.M., with an extra pint in the night. Now we are advised to add to this, "plenty of meat cooked to taste."

Such treatment would be apt to produce disturbance in a normal stomach. Supposing that two or three times in the twenty-four hours meat is given. Study of the gastric contents has shown among other things that the presence of lactic acid is very apt to overcome and destroy the normal hydrochloric acid of the gastric juice, therefore meat and milk are really incompatibles in gastric digestion.

Moreover, the administration of food in the amount proposed at the intervals suggested does not allow the stomach to have the physiologic rest that nature demands. As a matter of fact, in most tubercular patients the stomach is dilated, is slow in the digestion of foods and often requires the addition of hydrochloric acid rather than the administration of anything that would tend to overcome or destroy what may be already there. Thus we see in the food suggested, even without the medicine, there is reason for the gastric disturbance that occurred in all of my cases. Now let us analyze the prescription for internal use; of creasote and essence of peppermint each dose contains the small amount of 0.05 Gm., a little less than 1 minim, the daily amount administered being not more than 0.30 Gm. of each, that is about 5 minims. Each dose has combined with it 0.10 Gm. (about one and a half minims) of chloro-

form and 1.20 Gm. (about twenty minims) of glycerin and enough alcohol to make up the teaspoonful. Every one of the constituents of this prescription (with the possible exception of the peppermint) is irritant to the mucous membrane even when diluted with considerable water.

I tried this method of Carasso's with several private patients also. In every case except one, the gastric distress occasioned by the prescription was complained of.

The conclusions that I should draw from my observation of the trial of Carasso's method are: that the internal treatment is unphysiological and is very apt to cause disturbance of digestion, the very thing above all others that is to be avoided in the treatment of tubercular patients; that the inhalation of peppermint is valuable and deserves further investigation. There is now in process of erection at the Erie County Hospital a special building for the care and treatment of patients suffering with pulmonary tuberculosis. In this building we are to have two inhalation chambers so constructed that the patients are surrounded with air saturated with the agent to be used for medication of the respiratory passages.

At some future meeting I hope to be able to make a report that will show better results from a more rational mode of procedure.

#### DISCUSSION.

DR. AMOS of Baltimore—I should like to speak for a few moments on Dr. Rochester's paper. About fourteen months ago Dr. Osler, of Johns Hopkins Hospital, gave me the care of the treatment of the tuberculous patients in the out-patient department for the purpose of trying Carasso's treatment. In all I have had some eighty-five to ninety cases of tuberculosis, and in these cases about sixty have been treated now for twelve months. In all respects I may say that Dr. Rochester's conclusions tally with my own. I was startled by reading the extract from Carasso's article, in which he laid claim to the fact that under this treatment not only was there amelioration of all the symptoms, in no matter what stage of the disease the patients might happen to be, but that he also claimed that in thirty-nine cases, some of which had cavities, if I am not mistaken, there was a disappearance of the tubercle bacilli in all cases in from thirteen to sixty days. In all cases that I treated, the tubercle bacilli were demonstrated in the sputum. In only two cases I can vouch for the disappearance of the tubercle bacilli. One occurred after the patient had been in the Adirondacks for three weeks, and the other occurred in a working girl here, who had no sanitary surroundings, this last being really the sole case in which the treatment itself might fairly account for the satisfactory result. In over 50 per cent. of the cases there was an increase in weight for a short time, and then a diminution in the weight, so that in order to keep the weight up, the treatment was modified and increasing doses of creasote were given instead of stationary ones, these sometimes running as high as 14 to 15 minims three times a day. These cases were in the out-patient department, and it is very difficult to carry out any system of diet in a dispensary. The fact that the amount of liquid necessarily given in the twenty-four hours would disturb even the healthy normal stomach is a great argument against Carasso's treatment. We contented ourselves with trying to have super-alimentation, with more solids and less fluids. I do not see how it is possible for Carasso to verify his results in pulmonary tuberculosis, if the disease is the same in Italy as in this country, and I can not imagine how he can get such results as he claims to have obtained.

In all his cases there was tuberculosis only of the lungs. There was no tuberculosis of any other portion of the body. But in some of my cases there were lesions of other organs. I should say that in over 75 per cent. of the cases I have treated there was only pulmonary tuberculosis. The lesion occurred chiefly in those cases in which there was only a slight infiltration of one apex or the other. In one case there was a notable diminution in the number of bacilli in about three weeks, with a cessation of the night sweats, and improvement of the appetite, but no gain in weight.

In some of the cases that have now been on treatment for

fourteen months they still cling tenaciously to the inhalation night and day, although they are almost on the point of death. The oil of peppermint, however, seems to relieve them more than anything which I have been able to give them in the way of internal medicine. I am now trying to find the oil of peppermint in the urine or any other secretions. I have not done any active work on this, however, for the last three or four weeks.

DR. DENISON, of Denver, Colo.—I have a great deal of experience which leads me to indorse Dr. Rochester's conclusions for the use of creasote, and I have stopped a great many patients who were using creasote, because of the gastric disturbance which resulted. I came a great way to ask Dr. Paquin of St. Louis, what treatment he had carried out with his horse to get his horse blood serum in order to induce an immunity by its use in tubercular cases. I am sorry he is not here. He issued a paper in which the case was presented, a great deal like the play of Hamlet with Hamlet left out. The milk in the cocoanut was not there. What had been done to those horses to create the immunity-producing serum? We ought to acknowledge that we have come to the conclusion that there is no cure of tuberculosis except what is accomplished through strengthening the resisting power of the individual, or creating an immunity in the individual blood. So far as strengthening the power of resistance in the individual, there is no remedy equal to climate, and that connected with the lessened pressure of the air as we have it in the Rocky mountain region of this country. This question is settled in my own mind by the experience of twenty-two years with 3,000 cases.

I believe, gentlemen, that we are on the road to curing tuberculosis through the means of creating immunity in the individual. I have had 137 cases that I have treated with tuberculin; there were 27 cases of exsection, two or three of them cases of total exsection, who are now living and were treated two or three years ago on the average, and consider themselves pretty well. There are many of them claiming to be in perfect health. I have not had the bad experience that the fear of the profession would indicate that physicians would have in using that remedy. It is a severe remedy, and it needs discrimination, and the most careful diagnosis, in order to be successful.

DR. KARL VON RUCK of Asheville, N. C.—I have been very much interested in the two papers which have been read, and in regard to Dr. Parsons' paper I only wish to say that I do not believe that tuberculosis of the lymphatics and glandular apparatus as a rule precedes tuberculosis of the lungs. I do not think it is possible that suppuration can be produced by stasis of the blood, and do not think it is worth while to spend much time on that point. The production of tubercular tissue is not due to stasis, but is due directly to the tubercular bacillus, and the experimentation in this respect is so complete that this question is settled. I am glad to see that Dr. Rochester has so carefully followed up this work. I had preparations of peppermint and menthol made, several years ago, and I came to the conclusion that I would not take up this other treatment in their stead. Dr. Paquin is expected to be here, and I do not wish to say very much about his work, any more than that I have been in St. Louis, and have looked up his work, and he has given me every opportunity of doing so. The method of procedure followed, to produce what he calls "immunity" in the horse is simply the injecting of culture fluid of the tubercle bacillus in small quantities into the jugular vein, and then taking the blood serum and treating human beings with that. I do not think that this work has progressed so far as to justify any conclusions one way or the other. He has never shown his horses to be immune; indeed, I do not believe that there is such a thing as immunity to be induced by that treatment; it is simply toleration. The Doctor was kind enough to give me some of his serum, and I took that back with me and gave it to a doctor for experimentation, and he injected a number of guinea pigs that had been infected with tuberculosis. Our guinea pigs promptly died within forty-eight hours. We found upon bacteriologic examination that the serum was full of bacilli, which are now being cultured. We have thought best to venture no more guinea pigs on the experiment, but we are injecting a horse, and we propose to introduce a serum which will be at least safe upon animals.

I wish to indorse the statement of Dr. Denison as to the great value of climatologic influences. Many cases can not be cured no matter what we may do; but I would impress upon you the careful management of the cases, so that they may have the greatest benefit, not only from the climate, but also from the other treatment, so as to take advantage of all the means offered in the direction of health.

DR. PARSONS—It seems clear to my mind that the outline of my paper is perfectly justifiable and logical. I regret that it was not more in detail. Regarding the treatment, I wish to say a word. I think we should not forget that catarrh of the stomach is a coexisting trouble with tuberculosis, and is a disease which should be specifically treated. I do not think that creasote has any beneficial influence on catarrh of the stomach; in fact, it is inclined to produce it, and should not be given internally. I have had very little beneficial influence from creasote in my experience. Climate is an essential treatment, and above all a regeneration and re-oxidization of blood cells is necessary.

DR. ROCHESTER—Mr. Chairman, I should like to say a word, before taking up my own paper, in regard to the position taken by Dr. Parsons, though I think he has been thoroughly answered by Dr. von Ruck. He says that there is a condition precedent to the development of tuberculosis, and this he calls a "pre-tubercular condition." Where he has such a state, it will be found upon physical examination that there is already tuberculosis present, even although it is not possible to demonstrate the bacillus, or there be no cough. I think, moreover, in all cases of pulmonary tuberculosis there is associated therewith tuberculosis of the lymphatic system. That I think has been clearly proved by observations of Winthrop on the subject in the New York Foundling Hospital, when in 125 autopsies there were found tubercle bacilli in the lungs themselves, though some of these cases did not present any symptoms of pulmonary tuberculosis. The tuberculous poison is taken in by the respiratory tract. As far as regards any pre-tubercular state, I think the only pre-tubercular state is anything which in any way reduces the resisting power of the individual, any weakness, any anemia, whatever. Personally, I do not believe in heredity in tuberculosis, except that we may inherit a poor constitution, and excepting also those rare cases, of which I believe not more than one in ten have been recorded, in which the fetus is tubercular. There is inhalation from the mother, and the contraction of poison from nursing at the breast of the tubercular mother. If we examine cases of tuberculosis in children who are supposed to have inherited this disease, we find that in the majority of instances it comes from the maternal line. This means that the child is constantly present with the mother and subject to contagion from her. I was glad to hear Dr. Amos's report. There is one point I desire particularly to emphasize. Several things have been said against the creasote treatment. I wish to stand up here and defend the increasing doses of creasote just as strongly as I can. By gradually increasing the dose, starting with 1 minim, and giving particular attention to the patient's general condition, there should be steady improvement. As to the irritation of the stomach by creasote, this may result if it is given in water, but I have found that it can be administered in claret wine, or in some of the clarets of this country—the California clarets acting very nicely, and being cheap and within nearly everybody's reach—or we can give creasote in mucilage of acacia, and have very excellent results in spite of the slight irritation of the stomach.

### THE TREATMENT OF TUBERCULOSIS BY INJECTIONS OF IMMUNIZED BLOOD SERUM.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY PAUL PAQUIN, M.D.

MEDICAL DIRECTOR, SANITARIUM FORTHROAT AND LUNG DISEASES,  
ST. LOUIS, MO.

Since the discovery of the specific nature of infectious and contagious maladies, many members of the medical profession have devoted their energies toward finding a specific treatment for each. Their efforts have been crowned with success in at least one of the most dreadful maladies of mankind, namely, diphtheria, and this was accomplished in the line of natural law. I have the pleasure to report that under the same law, I have obtained by experimentation and in therapeutics, very promising results in the treatment of tuberculosis.

Following the researches of various foreign and American authorities on the action of certain physi-

ologic products of the animal body on disease microbes, I have for some years experimented with blood serum of various animals on microorganisms in general, and more recently with horse blood serum on the bacillus of tuberculosis. The results of my experiments and the various tests which I have made in the human family, have been such as to warrant the expression that, in immunized horse blood serum, there exists the principle with which to fight tuberculosis in all its forms.

#### THE NATURE OF TUBERCULOSIS.

Tuberculosis is, without question, the most universal disease existing. It may affect anybody in any climate, and it is found sometimes to have existed in a mild form in people who die of other maladies. An Italian medical expert has demonstrated that a large portion of people living without any manifestations of tuberculosis whatever are, nevertheless, infected in the glandular system of some organ or other. I think it is Tizzoni, who has proved this fact by post-mortem examinations of a large number of people who had died from the result of accidents. This indicates that tuberculosis may have been a long time working in the constitution before any symptom can be detected, or before the patient can notice any trouble. We may conclude, therefore, that pulmonary consumption may arise from tuberculosis previously existing in the glands, and possibly it frequently begins thus instead of from direct infection by inhalation. Any way there seems to be no question whatever, that tuberculosis may exist in the system in a limited way, concealed for indefinite periods, and that the power which we call vital resistance, namely, the physiologic cellular property of the organization to resist the invasion of germs, prevents the bacilli from accomplishing serious disorganizations, until such time as certain parts of the being are weakened by some process or other, such as bronchitis, la grippe, pneumonia, typhoid fever, colds so called, etc., or when some organs are congenitally feeble in their cellular, germicidal (or defensive) powers, and thereby predisposed to succumb more easily to bacterial action. The nature of tuberculosis then is such, that in its incipency, when the first morbid process begins in the glandular system, in most of the organs except the lungs it can scarcely be detected, and even in the respiratory organs it is exceedingly difficult under most circumstances to be positive of its existence. Most minute, rigid and repeated examinations are necessary for even a doubtful diagnosis if we wish for absolutely clear symptoms for it. When we consider this fact in the presence of the usual clinical histories of the patients presented to the medical practitioner, it will be obvious to every one that the beginning of the treatment of this fatal malady is rarely when it is yet in its incipient form. It is almost always when some marked structural changes have already occurred in some important organ or several of them, that the opportunity for the diagnosis of tuberculosis is offered. Even if the bacilli are just making their appearance, it does not signify incipient tuberculosis as so many practitioners consider it; the disease is then already in an advanced stage of tissue alteration. The bacilli do not appear in the sputum before changes occur in tissue. Indeed, I feel sure that it scarcely ever occurs that a case of truly incipient tuberculosis, whether of the lungs or other organs, is purposely brought to a physician for

examination, and when it does occur, it is either not recognized or the physician fears to express his suspicion.

With these facts before our minds, we will be able to appreciate better whatever value or importance may be attached to the results that my colleagues and myself have obtained in the treatment of tuberculosis by the injection of blood serum, and what part, if any, the glandular system plays in this form of therapeutics. Every one of our cases were in a more or less advanced stage of the disease.

In January last, I presented to the St. Louis Medical Society, a report of twenty-two cases treated with immunized horse blood serum, in all of which there had been some improvement from injections practiced once a day on an average of two months. In some instances weight had increased to a remarkable degree, and the symptoms of the disease were greatly improved. It was, at that early period, the increase in weight was particularly striking, it having advanced rapidly to a degree beyond all expectations under the circumstances. These patients were at the City Hospital and the poor-house, where the diet is exceedingly meager, and for a time were treated against their will, and were discouraged in it by some one or other, so that there had been neither dietetic or mental influence playing favorably on their physique. All of them improved in weight, varying from one and one-half to twenty-two pounds in three to eight weeks. All of the twenty-two cases reported then are living to-day; all of them have improved more or less since, and more than half of them have been discharged from the City Hospital, considered sufficiently well to do work. These cases were in the second and third stages of the disease, had tubercular processes in one or both lungs, some of them with more or less infiltration softening spots, and some with large cavities. In several cases there had been, to the beginning of our treatment, more or less severe hemorrhages, and in every case emaciation was more or less pronounced. Bacilli of tuberculosis were present in all, and very numerous in the majority. The average number of consumptives in the St. Louis Hospital is between forty-five and fifty. We began with thirty cases, having taken one after the other in two rows of beds regardless of their respective pathologic conditions, which ranged from bad to hopeless. Two almost in the last gasp when we began, died within three or five days. Six were discharged because they rebelled the first or second week. Twenty-two we kept and treated almost daily from November 29 and December 1 to January 26, when I made my first report to the St. Louis Medical Society. The wards adjoining the patients treated with blood serum and where an average of thirty to thirty-five patients are constantly present, new cases coming in as the old ones die, were subject to the ordinary treatment. The number of cases in the latter wards between Thanksgiving Day, November 29, and April 15 was over thirty, while the deaths among our twenty-two patients were not only *nil*, but half of them have, as stated before, been discharged on their own request to go home or to work. These patients received no other treatment whatever than blood serum, and they were subjected to the most trying tests to see the actual results. In the first place, after the symptoms of tuberculosis had subsided to a positive degree and the health improved unmistakably, as will be explained farther, the serum

was stopped for two weeks, the weight began to decrease, and the symptoms gradually asserted themselves. On the renewal of the injections, the bad features again began to yield. During the course of three or four weeks more of serum treatment, smallpox occurred in the City Hospital. As a consequence, sulphur was burned in the consumptive wards, and repeatedly afterward for some weeks in the wards beneath. My experimental cases were in consequence forced to inhale the resultant acrid vapors, and to shift about in wards with open windows during the most trying, raw and damp weather we have in St. Louis. And yet, the improvement continued, interrupted, to be sure, by such a severe misfortune, but not arrested for any length of time in the majority. The results have been to diminish the germs in number, disintegrate them apparently, alter the morbid secretion materially, clear up infiltrations, arrest hemorrhages, increase the avoirdupois, improve the appetite, arrest the cough very materially if not totally, and induce restfulness and quietness. I have here three cases, two of which have undergone the above experience and one a long interruption of treatment.

In surgical tuberculosis also, sero-therapy is very promising. The following is a report of Dr. Cale, surgeon, on a case he treated:

"I inclose herewith, report of a case of knee-joint tuberculosis treated after operation with your anti-tubercle serum. Mrs. M., age 26 years, mother of two children, the youngest four months of age. History of two tuberculous in her family. Has enjoyed good health until one year ago, when she had some pain and stiffness in right knee. Was treated for rheumatism by some physician until two months ago, when she called another physician, who made the diagnosis of tubercular joint and advised an operation. I was called in consultation and found the right leg slightly flexed, joint swollen, but extremely painful on pressure; there was also ill-defined fluctuation. In fact, the knee presented a typical picture of tuberculosis. The patient had fever and some night sweats and could not sleep without morphin.

"I sent the patient to the Woman's Hospital, and found on opening the joint, the entire capsule in a gelatinous condition, also numbers of rice bodies in the synovial fluid; the cartilage almost dropped from the patella. There was a cheesy tubercular focus on each side of the head of the tibia, which was removed with a sharp spoon. An attempt was made to preserve the condyles of the femur to minimize shortening of the limb, but they were so degenerated that about one inch and a half had to be sawed off. As is my usual method, a drainage tube was inserted, the wound closed and dressed before the removal of the Esmarch. Patient slept well all night without a hypnotic. The dressing was not touched until the eighth day, when sutures and drainage tube were removed. Since that time (six weeks) the dressings have been perfectly dry and needed no change. She has had an injection of 20 drops of serum daily for five weeks, her appetite is good, she sleeps well and is gaining in flesh. The case was a particularly bad one, and had I not intended to use the serum, I should have made a thigh amputation, instead of an excision of the knee joint. While conclusions can not be drawn from one case, the use of the serum has undoubtedly greatly aided in the progress of this case. I have made a large number of operations on tubercular bones and joints and have seen hundreds of others made, but it is certainly an exception to see such a result practically under one dressing."

#### THE PRODUCTION OF THE SERUM.

The production of the serum is based on the known principle underlying immunization of animals. The horse is naturally immune to a remarkable degree to the germs of tuberculosis. It has been possible, very rarely, to inoculate the equine species, but not to produce any permanent disease, except in very rare (doubtful) instances, to say the least. Acting on this knowledge, which I have verified with numerous

experiments on the horse, consisting of inoculations of pure bacilli culture, it occurred to me that the physiologic resistance of horse blood serum to the action of the bacilli of tuberculosis and its products, could be so increased by a proper process of immunization as to render it valuable in therapeutics. The results obtained verify apparently, the preconceived notion. In a word, the process of immunization consists of the introduction into the horse of quantities of toxins, regulated by their action on the system, followed by the introduction of germs of consumption, in various states of alteration and dilution.

One of the most important questions with reference to the production of serum, whether it be for tuberculosis or diphtheria, or any other disease, is the healthfulness of the subject used. The horse seems to be the only one used for therapeutic purposes. No animal of this family should be utilized without a thorough examination, and absolute evidence that it is not suffering from some organic disease or other, or from any functional disturbance which may produce any kind of toxic elements in the blood. In any condition bringing forth changes of the physiologic processes in the system, whether it be during the course of an insidious malady, or a readily appreciable disease, or whether it be during the process of recuperation from a pathologic condition of any character, there exist in the blood, elements which, introduced into an alien body, sometimes produce very serious results. And by the way, it seems to me that this point has been overlooked, so far as I can judge from the literature at my command, by the various experimentalists who have produced antitoxin. In my experience, the various untoward phenomena which have been described as occurring after serum injections depend largely on conditions preëxisting or created in the animal. A thorough knowledge of the physiology of the horse is as essential for proper immunization, as a thorough understanding of the strength, nature, dosage, etc., of the agents of immunization. Certain bad results in sero-therapy, such as fever, may usually be prevented by proper care and choice of animals.

#### THE SERUM.

The serum produced from the horse, whether its immunity is increased or not, varies considerably according to the subject, according to the immunization process, and according to the number of successive times the blood has been drawn. Consequently, uniform results can not be obtained in therapeutics unless the greatest care is taken in testing the serum obtained after each withdrawal of blood. This is probably true of antitoxins for diphtheria. There occurs a time after several séances of this character, when animal toxins are formed in the blood during the process of recuperation, and these, by injections in the human organization, produce untoward effects. I have seen a high fever from a single injection of 10 drops of serum absolutely free from microorganisms and other products, and I have also seen the development of urticaria, erythema, and symptoms of arthritis and disturbances of the kidneys produced by serum which chemically seemed, and microscopically was, absolutely pure.

#### DISCUSSION.

DR. PAQUIN said—The operation of immunization is exactly that relied on in obtaining antitoxin for diphtheria. It consists, briefly, of toxin injections until the fever ceases to rise; first of culture fluid, then injection of dead bacilli,

until that ceases to produce a fever; then of living bacilli until this causes no fever. When we do not produce any reaction to the germs, we consider that the horse is immune.

DR. VON RUCK of North Carolina—As to the immunization of the horse, I understood from Dr. Paquin that he injected, in the first place culture fluid, subsequently dead bacilli, and then the virulent bacilli. Now, we know that a horse can acquire tuberculosis; in fact, there is no animal that is immune to tuberculosis. I have very serious doubts as to the propriety of injecting the living bacilli into the horse, without killing the horse and making the most painstaking bacteriologic examinations. I would by no means be understood that I wish to throw cold water on the merits of the investigation. On the contrary, I realize how difficult this work is; how many obstacles there are in the way to discovering a true path where no one has yet trod. Still, I maintain that the therapeutic application of serum in the human system is entirely premature, as the experiments are not complete. I hope that the treatment will be shown to be of value; and in our laboratories in Asheville, experiments are now being made with this serum. One of the specimens of serum that Dr. Paquin kindly sent us contained cocci, and we could not think of using it in a human being. As to the results that are shown they are certainly in some respects very encouraging, but I must call your attention to the fact that those cases have all been in more or less advanced stages; they are phthisical conditions rather than tubercular cases. If this is the specific medication, just the same as in the treatment of diphtheria with serum, and there are pathologic changes, you can not expect to remove the mixed infection; in other words, you can not expect to cure by specific medication and at the same time remove thereby the results as well. About ten years ago I conducted a small institution in Ohio, for tubercular conditions. We had no climate, except of the worst, but we obtained from 24 to 34 per cent. of excellent results in the first and second stage. Even in the first stage we got some good results. One of the patients whom I examined in St. Louis stated to me that before the serum treatment was begun he had gained seven pounds. Clinical experience must be preceded by careful experimentation. It is not an indifferent thing to inject the serum of any animal into a human being. As to the cases which are present, it would be useless to examine them now unless we had previously done so ourselves.

DR. DELANCY ROCHESTER—I should like to refer those gentlemen who are reporting recoveries in tuberculosis, to Flint's original observations in regard to tubercular cases, in which sixteen out of forty-four recovered without any treatment whatever. Tuberculosis, according to his clinical investigations—I should say typhus, because it was typhus—was a disease which was of itself limited, and tends to recovery, and that in a number of cases they recovered without any treatment whatever. I would like also to emphasize the fact that in cases well advanced toward cavity formation, and in cases in which there are actual cavities of the lungs, we have not only a plain tubercular disease, but a mixed infection, and that the specific treatment is to a great degree out of place.

DR. HOLTON of Oregon—I remember reading some time ago some experiments that were made in Geneva with treatment by the serum of the ass. It was claimed that this was superior to the serum of the horse, and attention was called to the fact that consumption is rare where ass's milk is used as food. In twenty-five cases which were reported, thirteen were said to have recovered, two had died, and nine were under treatment, not having been treated for a sufficient time to demonstrate the result. I think that we want to take into consideration that there is still some question about how much the bacilli have to do with the trouble. Experiments have shown that the juice of the muscle of an animal infected with tuberculosis, where there was no tubercle shown in the muscle at all, would on injection produce the disease. It has been shown also by Ernst that the milk of cows infected with tuberculosis, where there was no affection of the udder whatever, and where there were no bacilli in the milk, would by injection produce the disease; that is to say, there were tissues in the juice of the muscle, and in the milk, although the tubercle was not present in either of them, that produced the disease. Now, does the bacillus happen to be there, with the other substance as an attendant, or with it as a cause?

DR. PAQUIN—I am rather surprised that Dr. von Ruck has taken occasion to call attention to the fact that the serum was impure. I expressly stated that this serum could not be expected to be microscopically pure, as it had not received the proper treatment. There may have been cocci there.

The antitoxin of Behring contains microorganisms and yet it has been used. A few of these do not show that poison will follow from injection. He is right in saying that we must be exceedingly careful in the matter, but the samples which I gave him were not intended to be utilized except with the knowledge which I gave him that they had not been filtered. It seems to have been the object of the speakers to make it appear that I claimed that I have proved the case at once. I have made no such claim. I have made a report, and it is so far true. Out of twenty-two cases we have not had a death. Out of thirty-five cases in the other ward, during the same period, there have been several deaths. As to microscopic work, I beg to say that I have a means by which a man can see spores from tubercle bacilli; it is my belief that it is possible to do so. I have read of the experiments in Geneva, and I have tried the blood of the mule. It seems to be little different from other animals. They are, however, more subject to disease than the horse; more subject to disease which simulates rheumatism in men. Dr. Holton has mentioned the fact that tuberculosis has been inoculated from tissues not containing bacilli. If this is the case, perhaps there were spores in that juice, and they were injected!

## PULMONARY HYPERTROPHIC OSTEO-ARTHROPATHY.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY N. S. DAVIS JR., A.M., M.D.

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE AND CLINICAL MEDICINE NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, ETC. CHICAGO.

I have chosen this symptom group for description as it is one that has received little attention from American writers. It has been my fortune to find but one case described in the literature of this country. This was written by Dr. Packard<sup>1</sup> and published in the *American Journal of Medical Sciences* for June, 1892. In European literature I find more than forty cases described during the last five years.

The characteristic lesions were first pointed out by Marie<sup>2</sup> in 1890 and received from him their name. His attention was attracted to these cases by the need of differentiating them clearly from acromegalia, which he described first in 1886. He found that many observers confounded these disorders which in some respects resemble one another. Moreover he believed that the bone lesions of pulmonary hypertrophic osteo-arthropathy were always due to the absorption of a chemical irritant produced by a primary disease of the respiratory organs.

The affection may be defined as a chronic multiple osteitis, involving especially the terminal phalanges, which are in consequence greatly deformed and the ends of the bones of the extremities. These bone lesions follow a chronic disease of the respiratory organs.

Almost simultaneously, Bamberger<sup>3</sup> of Vienna, described the same lesions, and assigned to them the same cause. He, however, included among his cases, cases of congenital heart disease, which exhibited the same osseous malformations, although they could not be explained as due to the same cause. Endeavoring to prove the correctness of his surmise, that this form of osteitis was the result of a chemical poison absorbed from the lungs, pleura or bronchial tubes, Bamberger introduced sputa from one of his cases beneath the skin of animals, endeavoring thus to produce the characteristic lesions; but he was unsuccessful. The earliest and most widely accepted explanation of the clubbed fingers of congenital heart disease has been the existence of chronic cyanosis. But need of well oxygenated blood will not explain the cases of Marie's disease for it is not a symptom of it.

The fact must also be remembered that in most cases of congenital heart disease there are coincident chronic lesions of the respiratory organs such as passive hyperemia and bronchitis. Since the original description of this group of symptoms by Marie, other observers have found them associated with other than lung diseases—with congenital heart disease, with syphilis, and possibly with caries of the spine. It is evident, therefore, that the bone lesions can not be due simply, or always, to the absorption of a chemical poison from the lungs or pleura. It is a fact, however, that in very much the largest proportion of cases, they are associated with chronic sup-  
 puration in the respiratory organs.

Thorburn,<sup>4</sup> who has described several cases, all primarily of tubercular disease of the lungs, believes the lesions in the bones to be those of an attenuated tuberculosis. This view is not sustained by other observers for in many instances sputa examinations do not demonstrate tuberculosis. Möbius<sup>5</sup> has suggested that this form of osteitis may be due to a primary affection of trophic nerves, for a clubbing of fingers and enlargement of bones in the neighborhood of joints has been known to result from neuritis. He describes one case in which only those fingers whose nerve supply was interfered with, were affected. Orilard<sup>6</sup> has described a case in which there was the deformity of the hands characteristic of this malady, which he thought resulted from caries of the vertebral column, but even in this patient there was a chronic sero-fibrinous pleurisy on the right side. Three characteristic cases have been observed associated with syphilis. No lung or cardiac lesion was found in two,<sup>7</sup> of them; and no cause of the bone affection could be assigned, except the constitutional disease. In the third, which was described by Chretien,<sup>8</sup> gummata were found in the spleen, liver, and various organs of the body, and a cavity of irregular size, containing partly caseous and partly cretaceous matter, was discovered in one lung, as well as numerous small bronchial dilatations, which contained pus. It is therefore doubtful in this instance whether the affection was not due to the coincident lung disease rather than to the constitutional one.

We must conclude, I think, that pulmonary hypertrophic osteo-arthropathy is not a distinct disease as acromegalia is; but a symptom-group, oftenest coincident with chronic lung affections, rarely with diseases of other organs and with syphilis. From the analogous action of some chemical poisons, such as phosphorus and arsenic, and the well-known tendency of certain infections to involve bones and joints in inflammation, it is probable that this chronic osteo-arthropathy is due to a toxemia which finds its source in the respiratory organs when they suffer from certain chronic diseases. It is best, therefore, to retain the appellation which Marie has given to this group of symptoms, remembering, however, that pulmonary hypertrophic osteo-arthropathy does not signify a pathologic entity, but an affection commonly associated with disease of the respiratory organs, although having at times a different origin.

The symptoms can perhaps be best depicted by describing a typical case:

A boy  $1\frac{1}{2}$  years old came under my observation a short time ago with the following history: When about 1 year old he had pneumonia. Since that time he has coughed more or less constantly, and has frequently expectorated large quantities of purulent sputa. About one year after the primary pneumonia, his parents noticed that the ends of his

fingers and toes became deformed by enlargement and that his wrists and ankles were increased in size to an abnormal degree. He required shoes several sizes larger than children of his age usually wore. His family history threw no light upon the origin of his malady. His parents are poor and in consequence he has not had constant medical aid. He appears as tall as children of his age usually do; fairly plump; his face is well shaped, although his expression is dull; his nose is short and somewhat broad; ear lobes a little thick; cheeks full; lips rather large, especially the right half of the lower one which is slightly pendent. His teeth appear quite normal, and his jaws and tongue are not enlarged. The skin on all portions of his body is smooth, soft and quite natural in appearance. His neck is slender. The thyroid and lymphatic glands about it are not abnormal. His body is well proportioned. There is no spinal curvature, although a dorsal kyphosis has often been observed in this affection as well as scoliosis. Comparative immobility during respiration and enlargement of the left half of the thorax is noticeable. The lower intercostal spaces on that side are not observed because of their distension, although readily seen upon the right side. The apex beat of the heart is invisible. Palpation of the chest reveals only the smoothness and distension of the left side. On percussion the whole of the left side is found to be absolutely dull, both in front and behind, and from the clavicle to the bottom of the thorax. On the right side, resonance is quite normal, except that between the third and sixth ribs, and extending about an inch to the right of the sternum there is an area dullness, due evidently to displacement of the heart to the right side. The respiratory sounds over the right lung are strong and exaggerated; over the left lung they are entirely wanting, except just beneath the clavicle and in the upper half of the left inter-scapular region, where there is consonant bronchial respiration.

It is evident that an effusion completely fills this boy's left pleural cavity and compresses the lung against the posterior and upper wall of his chest. As he has been expectorating from time to time, large quantities of purulent sputa, it is probable that the effusion is purulent and has been partly drained through the bronchial tubes. The effusion has existed at least a year, for as long ago as that, his parents were told that his left lung was useless. There is no disturbance of appetite, digestion or interference with the functions of other viscera. His parents say that at times he is feverish, especially just before and when expectorating large quantities of purulent sputa. His pulse is quite normal as regards fullness, force and rapidity, and when seen by me there was no increase of bodily temperature. The bones of the body are not deformed. Nor are those of the upper arms enlarged. But both wrists are considerably thickened and broadened. There is no interference with the motions of these joints. The metacarpal bones are not affected, but the first phalanges of the fingers are abnormally large, especially near the first finger joint. The second row are little or not at all affected, but the terminal phalanges are enormously and most characteristically enlarged. They are greatly broadened, and at the same time greatly thickened. The nails are abnormally arched, both laterally and longitudinally, so that they curve over the finger ends like parrot beaks. The last phalanx of the thumbs measures 6 c.m. in circumference and of the middle finger 5 c.m. The enlargement of the wrists and of the fingers is so great that it creates the impression of a general increase in size of the hands, although a genuine increase is not observable in the carpo-metacarpal regions. Precisely the same changes are visible in the feet. The ends of the toes, especially the big toes, are clubbed and greatly enlarged. The ankles are considerably thickened, as are the bones about the knees. The joints of the knees are not distended with fluid but the lower ends of the femurs are much enlarged. The hands and feet are mobile but the knees are slightly stiffened. There is no tenderness about the joints and never has been much.

The parents of this boy say that he has rarely complained of pain, although there are times when he seems inclined to play less than usual. In some other cases pain has been a prominent symptom. It has, however, rarely confined a patient to bed, although it has often restricted the use of the extremities. Pain is most apt to occur at the onset of the bone affection and is rheumatoid in character. Although in a small proportion of cases the onset of these lesions

is painful and somewhat abrupt, as a rule it is insidious. A striking and characteristic feature of this malady is the symmetrical distribution of the changes in bones and joints.

As yet it has not been possible to obtain samples of the sputa or urine of this patient for examination. When urinalyses have been made in similar cases no marked abnormality has been found. Legrain,<sup>10</sup> who investigated with unusual care the chemical composition of the urine of one patient in whom these lesions developed in infancy, and persisted up to the time of the examination, when he was 25 years old, found the quantity voided daily to be normal or only slightly increased. Its specific gravity was normal; and it contained between 14 and 15 grams of urea per liter; about 13 grams of chlorids and 1.6 of phosphoric acid. The proportion of earthy phosphates to alkalin phosphates was as 4 to 5. He found .07 of a gram of magnesia per liter of urine and .216 of lime. This is twice as much lime as normal, in proportion to the amount of magnesia. Legrain discovered that when acids were administered to this patient the amount of lime was increased still more. He was led to investigate particularly the proportion of lime and magnesia voided, by some observations of Chabrie which he quotes; the latter found that the affected bones in this disease contained comparatively a small amount of lime salts and proportionately a large amount of magnesia.

Post-mortem examinations of the bones have been made by Bamberger,<sup>3</sup> Therese and Rauzier.<sup>11</sup> They find in varying combinations an increase of synovia, enlargement of the epiphyses, erosion of the cartilages in some of the joints and enlargement of the long bones just above the joints, and sometimes along almost their entire length; thickening and adhesion of the periosteum in places, and the formation of wart-like growths of new bone within the periosteum; occasionally also they have observed central rarefying osteomyelitis.

These lesions may develop at any period of life, from infancy to old age; although oftenest in the earlier years of adult life. They occur most frequently in males.

Of affections of the respiratory organs with which this osteo-arthropathy seems to be associated, tuberculosis, empyema, and bronchiectasis are the most common. Cancer and sarcoma of the lungs with complicating bronchitis and pleurisy are among the rare concomitant affections.

A diagnosis of pulmonary hypertrophic osteo-arthropathy is usually not difficult. The peculiar and characteristic clubbing of the fingers resembles no other affection, except the common hippocratic finger or drumstick finger, from which it can be distinguished by the involvement of joints and other bones than the terminal phalanges. The close resemblance of these affections and their association with similar diseases makes it probable that the former is an exaggeration of the latter. The shape of the terminal phalanges, the location of the enlargement of the other bones, their shape, the non-involvement of the cranial bones make it easy to distinguish this affection from chronic rheumatic arthritis, lioniastis ossea, gigantism, and the commoner tubercular or syphilitic joint lesions. It is easier to confound it with acromegalia, although such confusion will not happen if close attention is paid to the characteristic symptoms of the latter disease. In acromegalia the ter-

minial phalanges and finger nails are not disproportionately enlarged and deformed; the fingers, as a whole, are uniformly and proportionately enlarged. The same is true of the toes. The metacarpal region of the hand, and the metatarsal region of the foot is much increased in size, especially in proportion to the wrist. Kyphosis is usual, but it is generally cervico-dorsal, not dorso-lumbar, as in this affection. In acromegalia the inferior maxilla is greatly enlarged, and so protruded that the teeth of the two jaws often can not be approximated perfectly. The nose, ear lobes, lips and tongue, are very much increased in size. These deformities may interfere with speech, mastication and deglutition. Acromegalia is also not associated with any disease of the lungs but with an enlargement of the pituitary body and consequently commonly with disorders of vision.

Improvement in the bone lesions has very rarely been observed. Monssous<sup>12</sup> saw one case due to empyema, in which drainage and thorough cleansing of the pleural cavity was followed by a diminution of the deformity of the fingers and toes. Gillet<sup>13</sup> noticed similar improvement in another case, follow drainage of a tubercular cavity. One<sup>7</sup> of the cases of supposed syphilitic origin also recovered after a course of specific treatment. Another case has been reported by A. Desmons<sup>14</sup> and W. Binand, which they treated by subcutaneous injections of tissue extract, made from the lungs of healthy sheep. These injections were made for several months, without injury or noticeable discomfort to the patient. The deformity no longer increased. The patient improved in general health. And what was more noteworthy a thoracic synovus which had persisted for years and grew out of an empyema that caused the osteo-arthropathy closed perfectly. At the same time, ease in the flexion of the digits and muscular power in the hand increased. Motion in the joints of the feet and legs, became so much freer that the patient could walk without a cane, upon which he had long been dependent. A single trial of so novel a treatment is suggestive but not demonstrative of its utility.

The result of treatment in the case which I have described can not be related, for the child has come only recently under my observation, and as yet it has been impossible to execute the surgical treatment which is required. Aspiration, and if the effusion proves to be purulent, as it seems probable that it will, thorough drainage of the pleural cavity is indicated. By this procedure we may hope at least to stop the bone disease in its progress and possibly even effect a disappearance of it.

## DISCUSSION.

DR. S. SOLIS-COHEN of Philadelphia—It has been my fortune to meet with two cases of the affection so well described in the paper, and to find in one of the cases a little more difficulty in discriminating the case from acromegalia than either my reading or the paper just laid before us this afternoon would seem to indicate. The point, however, upon which from further reading and from a study of these cases I would be inclined to lay greater stress, is the broadness of the hand in acromegalia, as contrasted with the length of the terminal phalanges in hypertrophic osteoarthropathy. In both instances under my notice there was associated chronic pulmonary tuberculosis in aged subjects. It is quite common, however, to meet with kyphosis, and with the hippocratic finger-nail in these subjects, especially in the debilitated and poverty-stricken people whom we meet at the Philadelphia Hospital, and I have thought that the affection discriminated by Marié and described this afternoon by Dr. Davis, is after all, as I think is Dr. Davis's opinion, merely an expression of a commonly encountered condition. If we were to class as pulmonary hypertrophic disease of the joints every case of empyema, or other suppurative thoracic affection which is associated with thickened terminal phalanges, with curved parrot-beak finger-nail, and so on, I think I could show two or three dozen cases at a moment's notice. Therefore, I would lay stress upon the involvement of the wrist and ankle joints before consenting to the diagnosis of this condition, which is again a further point of discrimination from acromegalia, in which the wrists and ankles as a rule are not affected. The condition is one of extreme interest, forming as it does one of the great group of affections to which clinical attention has so lately been directed, namely, the trophic results of chronic toxemias. I use these large expressions, which are somewhat vague, for the reason that I have not yet determined, or I think are we in a position to ascertain just what the toxemia is, and just what the exact pathologic and etiologic relation of the affection is. Still, it is trophic, in so far as it is a disturbance of of normal secretion, leading to excessive development of certain structures at the expense of others. In these cases there is excessive development of the bony tissues, in rheumatoid arthritis also development of the bony tissues with destruction of others involved in acromegalia, excessive development of subcutaneous tissues in myxedema. Here we have a large group of cases of perverted trophic conditions. That all will be shown to be due to some error in embolism will hardly be doubted. The evidence seems to prove that in this case it is some toxin, developed from the presence of pus within the body, whether that pus be formed in one disease or in another. I have listened with great interest to Dr. Davis's paper, and have learned a great deal from it.

DR. DAVIS—At first I was somewhat in doubt as to whether this case was not one of acromegalia, because of the enlargement of the hands and feet, and because of the dull expression of the patient, broad face instead of oval one, and thickening of the lips. It was perfectly evident on careful examination that there was no enlargement of the jaw, which is so characteristic of acromegalia. There was enlargement of the terminal phalanges and no increase in the size of the palm of the hand, and no thickening of the tissues outside the bones. The diagnosis was thus made clear in this case of pulmonary hypertrophic osteoarthropathy. Upon these features we have to depend in making our diagnosis.

## MEASURES CALCULATED TO MODIFY ACUTE INFLAMMATIONS OF THE RESPIRATORY TRACT.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY H. B. SEARS, M.D.

BEAVER DAM, WIS.

No single remedy or measure can always be relied upon to afford relief in any acute disorder, as the disease itself is often but a climax in a pathologic process, the divergent lines from which, radiate to a series of inherited or acquired causes; the most important of which must receive consideration of him who would stay the process of disease or assist nature in restoring to health.

Undoubtedly there are many measures utilized in therapeutics, identical in effect; also more than one way by which a pathologic process may be turned to a healthful issue.

We find ourselves to-day confronted with quite a number of methods for treating acute respiratory troubles; each of which, undoubtedly, possesses merits peculiar to itself and well adapted to meet certain indications which arise in these affections; but that any one remedy or means can fulfill all the indications or be applicable in every case could not be claimed, much less substantiated. One becomes expert in the use of a remedy or measure the same as in a certain surgical procedure; and one may also become blinded to the defects of a remedy or measure because of over-confidence in the same. We can only become right eventually by comparison of thoughts and experiences.

One urges us to use cold water locally or generally, one pilocarpin, another digitalis, others strychnia; another values hypodermoclysis; still others urge the expectant plan of treatment, combating a symptom here and there as it appears too prominent, asserting there is no way to shorten the inflammatory process and that the physician's duty is to watch, but act only when positive indications arise.

The writer desires to call your attention in a general way to conditions found in asthenic cases, prostrated with acute respiratory inflammations. Infancy and old age claim the larger share, but all ages furnish us with examples. Reference is made to the whole respiratory tract, because all parts suffer more or less in common, and treatment for one part is not wholly inapplicable to the rest of the tract; weakness or vigor having their respective influence upon the whole tract much the same. The intention is to look at the subject from a normal anatomic and physiologic standpoint, noting the variations in local nutrition and elimination and instituting treatment, in part influenced by the conditions existing just previous to the onset of the acute inflammation, and taking into consideration microorganisms or their chemic products only so far as defective nutrition in a part offers to them a suitable feeding and propagating ground.

All but a small percentage of the deaths in acute respiratory inflammations result either from excessive secretion of mucus or heart failure. These facts led the writer to look for prompt means of checking secretion in the respiratory tract, also those calculated to bring about the best possible heart action; appreciating the fact that not only healthy tissue metamorphosis but also the excessive changes occur:

ring during the inflammatory process are much influenced by the condition of the heart and capillary circulation. Every practitioner of experience has, probably, been impressed with the tenacity with which bronchial catarrh clings and the slowness with which resolution takes place in the lungs of subjects having a sluggish circulation. We have of these two main classes: first, the spare or poorly nourished in whom vitality is generally low and with whom the matter of nutrition is the subject of all importance, everything else being secondary thereto; second, a class not feeble in appearance, for they look full blooded and well nourished, but when your finger touches the pulse you perceive it is small and rapid. They are short of breath and a degree of cyanosis is present in the extreme cases. You may discover a heart murmur and you may not. Râles may be heard here and there over the lungs; quite frequently even when they feel their best. They have great thirst and demand large quantities of cold water, or something else, to quiet the inward burning. We will not go into further detail or speculate as to the different lesions which may have brought about an approximate of this condition. They are not confined to any age or condition in life. The defect in the power of the heart (from whatever cause) has brought about varying degrees of blood stasis, so that the venous system and lymph channels can not unload themselves nor remove the transudation which has occurred into the tissues of the lung. Elimination is much interfered with as well as nutrition. In these cases pilocarpin would be dangerous and heart stimulants alone would, ordinarily, fail to accomplish the desired results. The too common advice to give your fever patients an abundance of cold water (in these cases above all others) would, in the writer's opinion, but make their death more sure.

This condition, against which we are striving, is begotten of a feeble heart and an over-abundance of fluids, which, on account of the lack of tone in the circulation fails to be thrown off by way of the kidneys. Heart stimulants alone might relieve the edema of the tissues by unloading the distended veins and lymph channels, provided the condition of the heart would allow that degree of forcing, but there would be great danger of exhausting or injuring it before the work was accomplished. What seems to be needed first in these cases is depletion, not with the lance (although that might be a successful measure), but by catharsis, vigorous in proportion to the degree of stasis and depletion needed. Then the heart stimulants or tonics will work like a charm, diuresis will be induced and the dilated veins and lymph channels can easily be brought to an approximately normal condition, relieving the tissues of surplus serum and waste products. Then the exhibition of remedies lessening secretion in the respiratory tract, together with those having a tonic effect upon the vascular and nervous systems will, as general measures, do much to avert the dangers which await adynamic cases prostrated with bronchial and pulmonic inflammations.

If this is done we feel that the advice favoring the use of emetics in children and the lance in adults when dyspnea and cyanosis supervene, will not often be needed. By emesis we temporarily relieve the collection of mucus, but excite renewed secretion, very likely necessitating a repetition of the dose, each time increasing the fatal tendency. By bleed-

ing, some of the resistance to the weakened heart is removed, together with waste products, also valuable corpuscular elements of the blood, which will be sorely needed in convalescence should that stage be reached. All of this could be more safely and as surely accomplished by derivation by way of the bowels and kidneys, and the exhibition of heart stimulants and tonics, without the loss of valuable tissue elements.

The condition of the heart and capillaries should determine the use of heart stimulants as well as the efficiency of elimination; also the amount of fluids which the case will bear. When heart tonics are most indicated abundant fluids, most certainly, are not.

Ingestion of fluids does not of necessity increase tissue change or elimination. With a vigorous circulation the ingestion of water may flush emunctories, assisting greatly the throwing off of waste products; but if the circulation be weak, the accumulation of fluids in the body tends still more to embarrass the already failing heart.

Julius Glax made special observation in fifty-three cases of fever, endeavoring to determine if the human body retained water in the tissues during fever or is deficient in water. The amount of water ingested was noted, also the amount of urine passed (cases in which diarrhea was too free were excluded). He concludes that there is a conservation of water during fever, with an increased elimination in convalescence. His explanation is, that at the onset of the fever while the blood pressure is yet high, the diuresis occurs, but a diminution ensues as the pressure becomes lower and a still later increase as strength returns. An increase in the ingestion of fluids increases the elimination in most cases *only* after defervescence has begun, while during the height of the fever, diuresis appears to be more favorable the more limited the ingestion.

The writer would offer, as applicable in many cases of acute respiratory inflammation, the prompt exhibition of belladonna and turpentine for the purpose of abridging or modifying the local process. They have seemed to prevent excessive secretion of mucus in bronchitis as well as lessen the amount of exudation in lung inflammations; and, in conjunction with an effort to maintain the best possible circulation of the blood, have yielded results which encourage the writer to bring the subject to your notice.

In the early stage of respiratory inflammations, before excessive secretion begins, they seem to soothe the mucous surfaces and prevent much trouble. If secretion is already considerable, derivation by way of the bowels, together with the toning up of the heart will enable them to check the secretion of mucus, prevent accumulation in the dependent portions of the lung, or extension of the inflammation by contiguity. In children and feeble subjects this is a matter of no little importance.

Digitalis, as a type of heart stimulants occupies a very important place among the remedies utilized in combating respiratory inflammations, but it should not be forgotten that observation indicates that with high temperature or edema it is not absorbed, or, at least, is ineffectual until the temperature is reduced or the edema somewhat relieved by purgation. An additional advantage of the above mentioned plan of treatment, is that anodynes and antipyretics may be given with greater safety when indicated.

## PRE-COLUMBIAN LEPROSY.

BY ALBERT S. ASHMEAD, M.D.

LATE FOREIGN MEDICAL DIRECTOR, TOKIO HOSPITAL, JAPAN.  
NEW YORK.*(Concluded from page 807.)*

I print here, side by side, photographs of loss of nose deformation by lupus, by syphilis, by leprosy. The leper apparently has lost his upper lip, with his nose. This last is taken from Leloir's well-known work. I also print the characteristic deformations of fingers and toes of lepers, according to photographs sent me by Dr. Morrow. I print also photographs of *huacos* pottery, representing deformations. Also a photograph showing leprosy tuberculation of the face. This mutilation of the fingers, and this tuberculation of the face, are the most striking features of the disease. Is it not probable, therefore, that if those ancient Peruvians had intended to represent leprosy in the *huacos* pottery they would have shown a tuberculated face or a deformed hand?

Destructive lesion of nose and upper lip, typical of syphilis. Pl. 122. Clinique de la Maladie Syphilitique. Par M. N. Devergie. Paris, 1826. Ulcers rouges du nez, des lèvres des palais et de l'arrière bouche avec carie des os.

There lives in France (Béarn), in the Pyrenean regions, a class of people called Cagots, who have deformations of the finger- and toe-tips, elevated and arched nails, fissures and cracks, sometimes ulcers of the epidermis and ungual matrix, a reduction of hair, more rarely certain deformations of the phalanges, and some anesthetic cutaneous patches. M. Magitot and M. Zambaco have studied these deformations and consider them as being of a leprosy nature, being supported in this theory by historical documents, local traditions and other proofs, etymological and philological. These people represent an instance of survival in extreme attenuation of the genuine leper, so widely spread in southwest France from the thirteenth to the sixteenth century.

In the Academy of Medicine, of Paris, 1893, in a discussion on leprosy, and on the question, "Are there in countries reported non-leprosy, as France and especially in its northern regions, also in Paris, vestiges of ancient lepra?" M. Leloir mentions a case of multiple cutaneous gangrenous plaques connected with a lesion of the nervous system, which might have been lazarine lepra. He also, in his report, refers to what he said previously on leprosy in Norway, and quotes three cases, in which the diagnostic of lazarine leprosy was imposed: "In these three cases," says he, "we are in the presence of French patients, born in France, of French parents, and who had never left their own country (Paris and the Department of the North). Certainly if these patients had lived in leper countries one would have found the diagnostic of the mutilating lepra, the lazarine lepra. As it is, these affections, are simply called problems. *Are not these degenerated leprosy vestiges of the lepra of old?*"

Lépre tuberculeuse devenue tropho neurotique, lepre mixte variée; tuberculose systematisée nerveuse. Lépre Norwegienne. Traité de la lepre, par Leloir. Paris, 1886. Pl. xi.

Leloir, at Lille, in two clinics, showed four cases of unnamed affections, simulating systematized nervous lepra, or mixed lepra. The first of these accidents was that of a man born in the vicinity of Cambrai, who had never left the region of the north, and presented all the symptoms of systematized nervous lepra.

The second was a thresher, 46 years old, pensionnaire at the General Hospital, born in the vicinity of Bergnes; he had never been a soldier and had never left French Flanders. This patient presented in the highest degree the characters of the systematized nervous lepra. M. Leloir made the histologic examination of the pus taken from the cutaneous ulcerations, and from a small fragment of skin bordering on an ulceration; he found nothing characteristic. He

found two bacilli, showing the histo-chemic reactions of the leprous bacilli, and tolerably well their characters; "but you know," says he, "how abundant the lepra bacilli generally are in leprous tissues."

The third observation concerns a shepherd, 66 years of age, born near Fauquembergnes (Pas-de-Calais), who had never left Artois and the Flanders.

The fourth observation was the case of a woman aged 58, who had never been outside of French Flanders. This was a quite remarkable case of systematized nervous lepra. At the autopsy, pronounced alterations of the nerves of the limbs were found.

Leloir mentions another case, in 1892, a patient of his service, born near Dunkerque, and who had never been outside his native country; he was affected with trophic troubles, muscular and cutaneous, resembling much, in certain respects, those caused by the systematized nervous lepra, but probably of syringomyelic origin; this gave occasion to M. Leloir to agitate

Huacos pottery showing characteristic deformation. Wine or water bottles exhumed with pre-Columbian Peruvian mummies, (Chaucan and Champeco). Bandelier collection, American Museum of Natural History.

again, in a clinical lesson, the question as to the persistence of the vestiges of ancient lepra in France.

"Taking ground on the phenomena observed in those subjects," says M. Leloir, "I remarked in 1885, in my clinics at the Hospital Saint Sauveur, that in these five observations we have to deal with subjects affected with lesions which resemble much those of systematized nervous lepra, deforming or mutilating; those of the systematized nervous lepra at the period of the achromic and hyperchromic specks; of the lepra called lazarine (systematized nervous lepra with leprous erythema, pemphigoid and escharotic) and finally, of mixed lepra."

Were these cases of true leprosy, as one would certainly be inclined to believe at first glance? But, if so, where was the lepra contracted? This objection, Leloir says, might, however, be discarded, if we supposed ourselves in the presence of autochthonous

lepra, of vestiges of the ancient lepra which covered Europe, and France especially, up to the middle of the fifteenth century. He emphasized once more the fact that quite possibly a disease, which at the death of Louis VIII. (1229), had necessitated the creation of 2,000 leproseries in France, and of 19,000 throughout Christendom, had not entirely disappeared from the countries where it was believed to have been extinct for centuries.

He adds, however, that such a theory could not pass from the domain of hypothesis, to the domain really scientific, unless the ken of future observers can be connected in an incontrovertible fashion with lepra, on the basis of a careful clinical, anatomopathologic and bacteriologic study.

Now in the five observations which furnished a basis for his communications, and his lessons, if the patients had much in common with real lepers, it must nevertheless be confessed that certain clinical details, (for instance, the absence of paralysis of the orbicularis of the eyelids, with anesthesia of the face, etc.) did not tally exactly with the lepra diagnostic, and that there was no bacteriologic criterium at all.

"It might, however," says Leloir, "be conceived possible that these cases of autochthonous lepra, vestiges of the ancient lepra, presented themselves to-day under an aspect slightly modified, the disease having, as it were, degenerated since the Middle Ages."

M. Leloir thanks M. Zambaco-Pacha, for giving fresh support to the hypothesis expressed by the Lille professor, in 1884, 1885 and 1886, by his works on the *Cagots of Bretagne*. Only, he thinks that M. Zambaco's labors do not give us the decisive, conclusive proof of the persistence of ancient lepra in the individuals described by him. "Until he finds in them, Hansen's bacillus, one must be allowed to doubt, in fact, one must doubt."

"I content myself with referring to the Chapter 'Diagnostic,' of my Treatise on Lepra, where it will be seen how difficult the diagnosis of this disease is sometimes. If what I say in that chapter, and what I said in 1889 in the *Annals of Dermatology*, in speaking of a patient of my service whose observation was published by my interne, M. Baade, and subsequently published again by M. Thibierge in the *Medical Society of the Hospitals*, is true, if lepra can be present unperceived before the most experienced doctors, if they are not perfect leprologists, it is not less reciprocally true that we must be extremely cautious, lest we confound several quite different diseases with lepra. This is especially to apply to the systematized nervous lepra, a real specific polyneuritis, which may be easily confounded with a number of affections of a tropho-neurotic origin.

"As I said in my Treatise on Lepra, it can easily be conceived that as systematized nervous lepra is nothing but a specific polyneuritis, many affections of nervous origin are confused with it. But even this specific character of the leprous neuritis is cause that in its character, in its evolution, in its dissemination, in its localization in certain nerves, etc., it presents characters so different from those we are used to observe, such a special stamp, that in general the diagnostic will be easy enough for a physician who knows something about systematized nervous lepra.

"I will conclude in a few words:

1. "As I have shown with regard to the region of the North and for Paris in 1884-85, and as has been

shown in 1892 by M. Zambaco-Pacha for Bretagne; there are in France persons affected with nameless diseases, bearing a strong resemblance to lepra.

2. "As I asserted in 1884-85, and as has been affirmed in print by M. Zambaco-Pacha in 1892, it is possible that we are in these cases confronted with vestiges more or less degenerated of the ancient lepra, which had invaded all France and Europe in the Middle Ages.

3. "This theory is plausible, suggestive, but it is still in want of a scientific demonstration founded on a set of facts carefully observed and carefully described from an anatomic-pathologic and bacteriologic point of view."

Thus we see that, if we had cases with such deformations as may have existed in Peru, and which the *huacos* pottery is claimed to represent, not even that would be sufficient proof of the existence of leprosy, as long as mutilation of hands and feet, and tuberculation of face, were absent. Evidence of tropho-neuritic destruction is not sufficient to make us assume leprosy. Nor would even syringomyelia, if it is existent in British Columbia, be proof of the existence of leprosy in pre-Columbian times.

There is a little pamphlet, published in London, 1889, by a member of the American Ethnological Society; it is entitled "Tepeu: the Hypothetical Migrations of Morbus Americanus." Tepeu is the Quiché name for syphilis, meaning also nobility. The author claims that the investigations among the Natchez, and the mound-builders of the Cumberland Valley, established one point: that the latter were the subjects of a constitutional malady, which produced certain textural changes in the osseous tissue, a malady which may or may not have been syphilis, but which was incontestably like syphilis in its pathologic lesions and may therefore have been lepra, "the pathologic counterpart of syphilis and by some writers regarded as essentially one with it."

I have myself attempted to show in an article entitled "Leprosy in America before the Advent of the Spaniards and the Negroes," published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, December, 1894, that the disease, leprosy, did not exist among the ancient Aztecs. The Natchez are supposed to be a connecting link between the mound-builders of the Mississippi Valley, and the ancient Aztecs. If the Natchez had been lepers, the Aztecs would have been lepers. Now, as I said in that article, and as Dr. Brinton stated before, the word *lepra*, to the ancient Spaniards, and the word *teococoliztli* to the ancient Aztecs, meant the same disease, which undoubtedly was syphilis. From which we may certainly draw the conclusion that the pathologic lesions in the remains found in the Cumberland Valley are more likely to be attributable to syphilis than to leprosy.

Mr. Henry C. Mercer, Curator of the Section of American and Prehistoric Archaeology, University of Pennsylvania, who has just returned from an exploration in Yucatan, says that he could not discover any proof of the assumed great antiquity of the Mayas, or of their migrations; he is inclined to hold quite opposite views. "The interment vase," says he, "must be proved to be pre-Columbian, if it is to be of any use in the argument, and this is not an easy matter. I am not altogether," says he, "satisfied with the syphilitic bones from Tennessee, but am open to proof. I know how collectors 'collect,' and should want to be sure that Bandelier had dug

up the Peruvian vases himself, and studied the whole interment. I found some crania on the eastern shore of Maryland not long ago, in an ossuary, which Dr. Harte, of the University, after examination says are syphilitic, but the ossuary may not be pre-Columbian. The description of these is already in MS. I know the need of exact archaeological work in Central and South America, where the first object has been to discover startling facts and 'beautiful specimens,' and trust you will be very careful in making use of what has been sent up to us by enthusiastic collectors."

I may say here that these *huacos* potteries which have been sent up by Mr. Bandelier are said, by competent archaeologists, to be pre-Columbian. Certainly, one of them, if dug out of a grave twelve feet deep, which contained a Pachacamac pre-Columbian skull, showing a syphilitic lesion, diseased frontal and parietal bones, must have some relation to the same skull; that is, represent the disease apparent in it.\* This cranial lesion is certainly due to syphilis. The plates in Devergie's "*Clinique de la Maladie Syphilitique*," Paris, 1826, present caries and necrosis of the frontal bone, of the nostrils and superior maxillaries, following chronic syphilis; exostosis and caries of the frontal bone and of the cheek bone, and its surrounding parts; caries of the frontal bone, nasal bones and ethmoidal bones, developed under mercurial influence, and a process of healing; exfoliation of internal table of the frontal bone, followed by caries and necrosis of that bone. These lesions are peculiarly syphilitic. In the same atlas will be found plates showing destruction of the nose and upper lip, strikingly like the deformations on *huacos* pots; scars of carcinomatous and rodent ulcers (syphilitic) occupying the left wing of the nose, almost totally the upper lip and left cheek, with caries of the cartilages of the septum, and the wing of the nose; rodent ulcers of the nose, lip, palate and of the throat with caries of the bone; irregular cicatrices of ulcers of the head; tuberculous and ulcerous cicatrices, with total loss of nose; tuberculous ulcer, loss of nose through the progress of ulceration caused by syphilis, consecutively developed after treatment by mercury; cicatrices of ulcer of the head, and others of the face, thought to be syphilitic, with caries of the upper jaw and the nose.

These lesions are identical in appearance with the lesions to be found in the *huacos* pottery. There is but one loss of nose, and apparent loss of part of upper lip, of a leper represented in Leloir's "*Traité de la Lepre*," Paris, 1886. The title of this plate is: "Tuberculous lepra changed into tropho-neurosis, mixed lepra; variety: systematized nervous tubercular leprosy in a Norwegian." This is not like *huacos* pottery, because there is typical leprous cicatrization and contracture of the connecting link of flesh between the lip and the lost nose. It is not a loss of lip. Besides, there is the usual leprous stenosis of the oral aperture, and general facial atrophy. These characteristics do not appear in any of the *huacos* specimens. Moreover, in the dry or atrophic form of leprosy, the only form which these vases could possibly represent, we should have crooked or mutilated fingers, and deformity of eyelids which in these vases never appear.

One thing more: to have the *lepræ bacillus* from a leprous country, say India or China, it is not only necessary that the bacillus be transported in a human

\* NOTE.—I have written to Mr. Bandelier for the exact facts.

body, but that the condition of life of the human body itself should be transported also. This point has been clearly explained by Hansen in his investigations on the conditions of leprosy among the Norwegians emigrating to Wisconsin and Minnesota. He found that while a number of lepers (of course not

change, that their conditions of life are not the same as those in Norway, and that therefore the conditions necessary for the life and well-being of the bacillus are absent.

#### CONCLUSIONS.

So far as I have investigated this subject, I consider myself justified in saying: 1, syphilis and tuberculosis are pre-Columbian; 2, that any deformation on American pottery would be more likely to represent lupus and syphilis than leprosy; 3, the pottery upon which the supposed leprous deformations appear, is beyond doubt pre-Columbian.

NOTE.—I may say here that I have examined many bones, in a disintegrated condition to be sure, dug up at Llujon, Bolivia, five miles over the Peruvian line, at a place called Tiahuanaco; also two skulls, at the same place, which probably are not so old as the disintegrated bones. These latter two skulls have the peculiarity of an open suture running down from the coronal suture of the forehead to the root of the nose. These skulls are, like the bones I mentioned, not only pre-Columbian, but pre-Inca. In none of these is there any evidence of leprosy or even of syphilis. What makes us look with some suspicion of leprosy at these Tiahuanaco bones in Bolivia is the probable relationship between the Micmacs of Nova Scotia and the Tiahuanaco races of Bolivia. The Micmacs are supposed to have come north from the southwest, and to have had relations with the Navajo and Apache Indians, and also with Peru, Yucatan and Mexico. Whether the endemic leprosy of Nova Scotia, supposed to have come with the Bretons, is at all connected with the Micmacs remains to be seen.

## SOCIETY PROCEEDINGS.

### ILLINOIS STATE MEDICAL SOCIETY.

*Abstract of the Proceedings of the Forty-fifth Annual Meeting, held at Springfield, May 21, 22, 23, 1895.*

#### FIRST DAY—MORNING SESSION.

The Society met in Central Music Hall, and was called to order by the President, DR. DANIEL R. BROWER, of Chicago, at 9:40 A.M.

Prayer was offered by the REV. F. W. TAYLOR, of Springfield.

The report of the Executive Committee was made by the President.

After the transaction of some routine business, the general session adjourned, and Section 1 was called to order.

#### SECTION 1.

*Practice of Medicine, Medical Specialties and Therapeutics.*

*Chairman, DR. E. P. COOK, of Mendota.*

*Secretary, DR. J. T. MCANALLY, of Carbondale.*

The Chairman made a few remarks introductory to the work of the Section, after which he called for the reading of the first paper, entitled

#### LITHEMIA,

by DR. C. W. HALL, of Kewanee. The author said there were three reasons for selecting this subject: 1, because its importance is not appreciated; 2, because it occurs much more frequently than is generally supposed; 3, because it is a condition medicine will remedy. Cases of lithemia generally present themselves with a history of long-standing ill health. Medicine seems to help for a little while. They complain mostly of indigestion. The health of these patients has been failing for a long time. They have no appetite, and when they do eat they wish they had not, for a heavy, loaded sensation follows eating which in time causes great distension of the bowels due to gaseous fermentation. Food is oftentimes vomited and it is very sour. Bowels are constipated. General weakness is present. Patients have no desire for mental work; they feel blue and despondent, and this latter condition varies with the amount of gaseous distension. Pain is generally present in the region of the liver or stomach and in the region of the kidneys. An empty faint feeling in the stomach before eating accompanied with dizziness and headache. The author emphasized the pain felt in the region of the kidneys. This pain takes a course down the ureters, the ureters being rather tender to the touch. The pain also extends to the meatus urinarius, and the urine smarts and burns. The urine is always highly colored and when cool very cloudy. We have a brownish smoky color of the urine, and sometimes a reddish deposit. Litmus paper gives a decided acid reaction. The cause of this is an improper oxidation of albuminous

Deformation of fingers and toes, from Dr. Morrow's collection of photographs.

known as such) had emigrated, in no case did he find a second generation leper, or that a case of leprosy had developed here from Norway not imported. He asserts that the reason of it is that their habits

substance taken as food. The gastric secretion in lithemia is especially affected and gastro-duodenal catarrh is probably the most pronounced symptom of the disease. In the treatment the author never fails to give almost perfect relief by the administration of nitric acid C. P. and phosphate of soda C. P. Nitric acid is given before meals in one or two drop doses in plenty of water; this lessens the acid secretion of the stomach. It is a great oxidizing agent, stirs up the torpid liver and is probably the best all round medicine to give in this disease. The sodium phosphate is given in the middle of the morning, afternoon and at bedtime, which acts very favorably on the catarrhal condition of the stomach and bowels. It neutralizes the acidity and dissolves the mucus. For gaseous fermentation the author gives creasote and assafetida with good results.

DR. E. INGALLS, of Chicago, contributed a paper on

#### SOME OBSERVATIONS ON MODERN THERAPEUTICS

which was read by the Secretary of the Section in the absence of the author. The paper stated some facts that indicate the very weighty obligations under which we rest for some modern discoveries in therapeutics. Therapeutics was defined as that branch of the science of medicine which treats of the properties, powers, action and modes of application of such agents as will prevent, ameliorate or cure disease. To learn that there was such a disease as cowpox, that it caused but little discomfort to the patient and left behind no harmful sequelæ, and that it rendered the system immune to smallpox, was, he thinks, the most important discovery ever made by man. It has added millions to the number of inhabitants on earth; it has given them exemption from suffering and has greatly augmented their wealth. Therapeutics requires very careful study, for there is no department that is more difficult to master. With most medicines it is impossible to determine by any scientific rules how they produce their effects. We know how some antidotes and antacids are curative, for their action is chemical, but in general we acquire this knowledge through empirical observation. We would never suspect from any examination of the medicine that morphia would compel sleep or allay pain, strychnia cause convulsions and death, that ipecac would produce emesis, or veratrum slow the action of the heart, except by administering them and observing their effects; and these effects are not uniform, for they will differ as they are influenced by individual idiosyncrasies, or by the varying substances they meet in the stomach or in the circulating fluids, and sometimes by vital forces that we do not understand. For these reasons therapeutic skill is only to be acquired through the most painstaking study and observation, but if these are given it will abundantly reward a student for his labor.

DR. ARTHUR R. EDWARDS, of Chicago, read a paper on

#### THE DIFFERENTIAL DIAONOSIS OF UREMIA AND ORGANIC BRAIN LESIONS, ESPECIALLY MENINGITIS, WITH REPORT OF OBSCURE CASES.

Uremia is usually readily differentiated from organic cerebral disease, yet confusion may arise in atypical cases. The main rule in diagnosis is to assume that uremic intoxication is the cause for nervous symptoms in nephritic subjects only when other causes can be excluded. Preëminent importance attaches to the presence of albumin, casts and to the amount of urine, although 1, nephritis may be unattended by albuminuria; 2, casts may be permanently absent; and 3, uremia may intervene when the amount of urine and urea is normal. (Citation of case of chronic parenchymatous nephritis in which casts without albumin were present.) If uremia is due to cerebral anemia, we must guard against confusion with cerebral anemia from other causes, but such albuminuria is transitory and unaccompanied by casts. Conspicuous cardio-vascular symptoms are valuable diagnostic adjuvants and yet not worthy of absolute confidence. (Citation of case of albuminuria and cardiac hypertrophy in which the clinical diagnosis was uremia while the autopsy disclosed meningitis and arterio-sclerosis.) Numerous alterations in the pulse may involve differentiation. The retinal findings are most important, for retinitis albuminurica is rarely absent in chronic nephritis leading to uremia. In certain cases the diagnosis is more difficult than that of any other cerebral disease. Uremia and meningitis have many symptoms in common—headache, convulsions, coma, dyspnea, vertigo, etc. Confusion is almost inevitable when partial contractures, focal paralysis, and temperature occur. In such cases the most experienced diagnostician errs. Broadly speaking, circumscribed convulsions and paralyses speak strongly for anatomic changes in the central nervous system, although they may rarely occur in uremia. This

point is scarcely recognized in the literature and the author of the paper collected published instances and reports four cases of his own, in which the most diverse focal symptoms appeared in uremia—crossed paralysis, ptosis, strabismus, temperature, delirium, hemiplegia, etc. The multiplicity and incongruity of the symptoms were best reconciled by a diagnosis of meningitis. In all the instances there were no microscopic changes in the brain, edema cerebri alone being present. Unusual focal signs may exceptionally occur in uremia. Convulsions may occur in one-half the body, opposite half of tongue and arm. Trismus, nystagmus and grinding of the teeth have been recorded. Rigidity of the neck, so common in meningitis, has occurred in uremia with consequent confusion in diagnosis. Opisthotonos, extreme in degree, complicated a plain case of uremia. Paralyses are rare and usually transitory. The combinations are manifold. Hemiplegia is the most common form, but exceptional combinations are found, *e.g.*, 1, crossed facial paralysis with hemiplegia; 2, crossed oculomotor paralysis and hemiplegia; 3, paraplegia; 4, hemiplegia with aphasia, amnesia and deafness; 5, hemiplegia plus nystagmus, diplopia and aphasia; 6, paralysis with conjugate deviation or glosoplegia; 7, tonic local spasticity with focal paralyses. In short, the writer has been able to find instances in uremia of almost every focal symptom or sign observed in disease of the central nervous system, combined in infinite variety and simulating the most diffuse intracranial processes.

#### TYPHOID FEVER.

A paper was read on this subject by DR. D. W. ALDRICH, of Galesburg. The author believes that the typhoid bacillus is an important factor in the disease; that it may be taken into the system through the mouth, air passages, and possibly the skin; that the spleen, liver, and intestinal tract afford soil in which to incubate and develop a crop of the bacilli which may prove to be master of the situation a few days or weeks later on. Typhoid fever is a disease of many symptoms or of few. Where the bacilli are not in any manner interfered with, the symptoms are many and severe in the extreme. But it is possible to interfere with the development and action of the bacilli in such a manner that their presence in the system is scarcely recognized by the symptoms they produce. It is for the purpose of bringing about this change that the physician is called in the case. Since August 1, 1890, it has been the author's custom, when called to see a patient with typhoid fever, if the stage of incubation is not passed, to apply ice water or ice bags to the abdomen for a period of twelve to twenty-four hours, with a view to interrupting what he presumes to be the incubating process, first using cloths wrung out of tepid water, gradually lowering the temperature until at the end of one hour, ice water or ice bags are used. It has also been the author's custom to administer carbolic acid and iodin with a view to disinfecting the alimentary canal, destroying the germs; to reduce the temperature; also to administer the sulphate of magnesia to wash out typhoid bacilli and other noxious matters which may find lodgment in the alimentary canal. The author then detailed the symptoms of two cases and the method of treatment, and closed by saying that since Aug. 1, 1890, with one exception, he had fed 182 patients of typhoid fever upon milk alone. The exception was a case in which beef tea was administered by the nurse with a view to rendering invaluable assistance to the physician. This patient died, but the other 181 patients recovered. The patients were allowed to take their milk either hot or cold. Other articles of diet were prescribed. Rectal feeding was resorted to in many very weak patients. The same article of diet, however, with the addition of a small amount of brandy, was alone made use of. Later in the disease, in some cases oils were rubbed into the skin at regular intervals and in sufficient quantities to aid very materially in upbuilding the system.

DR. C. C. HUNT, of Dixon, followed with a paper entitled "Antiseptics as Applied to General Practice."

#### TREATMENT AND CARE OF EPILEPTICS.

This paper was contributed by DR. GEORGE BOODY, of Kankakee. The author says this class of unfortunates are shunned by friends and too often by their nearest relatives. They feel that they are looked upon as outcasts by every one with whom they come in contact, and what wonder that they, unable to help themselves, at last become despondent and are driven to desperation, finding themselves within the walls of a hospital for the insane. Of 100 cases in the hospital, investigation shows that the greater number of them became epileptics in childhood. Of the cases that began in childhood, three-fourths of them were due to infantile con-

vulsions, ascribed to teething. Gray says that these convulsions are known to be due to defective development, which is itself brought about by defective nutrition and ought to be preventable. Fright is ascribed as a cause, but the author has been unable to find statistics sufficient to prove how important a rôle it plays. From a pathologic standpoint, epilepsy is divided into two great classes: 1, epilepsy from organic disease; 2, from a morbid state or condition and not dependent upon any other disease. The author then dwelt upon the symptomatology and diagnosis of the affection. He is a strong advocate of the establishment of epileptic colonies, and says that no State can boast of advancement in the treatment of the insane so long as it continues to permit the epileptic insane to be promiscuously scattered among the general insane. There should be an absolute separation of these poor unfortunates from the other insane, and their speedy removal to a home for epileptics should be the foremost thought in the minds of all those who are deeply interested in the welfare of the insane. Illinois ought to profit by the example set by Massachusetts, Ohio and New York, each of which now have separate homes for this most unfortunate class of individuals.

DR. HUGH T. PATRICK, of Chicago, read a paper entitled

#### THE COMBINATION OF HYSTERIA AND ORGANIC DISEASE.

The author first related a number of cases in which hysteria was combined with various organic diseases. These diseases include typhoid and scarlet fevers, rheumatism, puerperal fever and acute pelvic inflammation, as well as more chronic affections of various kinds. Instances were also given in which there was a combination of organic disease and hysteria as well as simulation on the part of the patient. It was particularly emphasized that organic disease of the nervous system was apt to be complicated with hysteria and illustrative cases were quoted. The fact was emphasized that, particularly, multiple sclerosis and syringomyelia are apt to be complicated with hysteria, and among the toxemias those of lead and alcohol show most frequently the aforesaid complication. He believes our semeiology to be sufficiently advanced, even in the obscure realm of the nervous system, to allow us to say that the different types formed by certain pathologic conditions and stamped by well-defined combinations of symptoms remain sufficiently distinct to be generally separated the one from the other. When two types occur in the same individual it is not really a mixture with which we have to do, but simply a contiguity and juxtaposition; consequently in a given case of organic disease the diagnosis of hysteria is aided simply by means of the so-called hysterical stigmata and other symptoms characteristic of this disease. The various stigmata were then briefly enumerated. Of these, the principal are the characteristic anesthetics in patches and the so-called glove, stocking or sleeve anesthesia being the most typical. A distinctive trait of most of these anesthetics is the fact that they do not interfere with cutaneous reflexes and automatic accomplishments. The hysterical eye affections were then alluded to, embracing the characteristic alterations in the visual field, monocular diplopia and polyopia, monocular amaurosis with binocular vision, anesthesia of the eyelids and conjunctivæ. The peculiarities of hysterical paralysis were then pointed out as distinguished from those of organic origin, as well as the characteristic differences between hysterical, organic and epileptic convulsions.

In conclusion, the author insisted that a severe hysterical affection might occur in an individual who had never shown any other hysterical symptoms; that such an affection might remain unchanged for years and be almost the sole sign of this omnivagant disease. Furthermore, that fever, a rapid or subnormal pulse, retention or incontinence of urine, loss of sexual power or desire, loss of pupillary reflex to light, and ankle clonus, although indicating as a rule organic disease, may occur as symptoms of hysteria.

DR. S. K. CRAWFORD, of Chicago, read a paper entitled

#### HEMIPLEGIA BY THE HEMIPLEGIC HIMSELF.

The author of this contribution was seized with left hemiplegia Aug. 22, 1892. There were serious and, to him, most sensible perturbations of the circulation in the base of the right hemisphere of the brain, prominently located in his mind by the sensations present. "The first sensations were those of intoxication, with a mentality like the country peddler's wagon, when a wrecked hind wheel is compensated for by a limber pole with the large end fixed upon the front axle and the wheelless spindle of the axle placed upon the swaying pole, while the topmost end brings up the rear."

Dr. Crawford said that he had treated six patients during the forenoon of the day of his seizure. His motions were awkward in the extreme, but weakness or marked prostration did not supervene until the approach of the lunch hour, when it became a prominent symptom and he walked to his bed chamber adjoining his operating room, threw himself upon the bed to doze the afternoon away, half sleeping and half waking, with no pain or distressing sensations of any kind, and with hearing and sight acute and perceptions unimpaired. The physical pain was nothing to be compared with the mental perturbations that were endured. As regards treatment, under the direction of his physician and by and with the consent of his consultants, he sent a gentle and continuous stream of electricity through the right hemisphere of his brain from fore to aft, and ranging downward from the right frontal to the occiput of the same side, daily for ten months, with a sitting of fifteen minutes at each and every employment. At each and every sitting the paralyzed muscles were awakened, as well as the dormant tissues, with massage, and a faradic or interrupted current. This treatment was supplemented by the employment of digitalin, strychnia, and minimum doses of quinin, and continued for some months after the employment of the electric current was suspended. Convinced that the treatment employed had been efficient, and when he could no longer detect any local pressure anywhere or observe any of that dazed or hazy condition about his being that so prominently prevailed in the earlier months of his illness, he began a course of specific nutritive treatment, by the exhibition of phosphorus in the way of medicaments and diet, and he was not only pleased but delighted with the results obtained.

The Address of SECTION ONE was delivered by DR. ROBERT LEUDEKING, of St. Louis, Mo., who selected for his subject

#### THE PRESENT STATUS OF SERUM-THERAPY.

A variety of theories exist in explanation of antitoxin production. The one theory advances that the antitoxin is the product of the reaction of the specific toxin on the albumin of the living body. It is a cell elaboration, the toxins acting as cell stimulants. A second view says, May not the toxins become converted into antitoxins? A third view is, that in infections, where bacteria invariably have place, these themselves in their disintegration indirectly yield antitoxins. As a consequence of these developments of scientific research, Behring shows us that the incorporation of such serum, possessed of these faculties, into a second animal, is followed by the development of a similar protective state. This was called passively acquired or indirect immunization. The next step in natural order is the application of these experiences by Behring and Roux to the treatment of disease, first in animals, then in man. Behring held and still holds that antitoxin destroys the toxin, neutralizes its effect. One writer has shown, however, that such is not the case. Toxin and antitoxin exist side by side. A mixture of the two, for instance, that will on injection leave white mice unscathed, may kill a guinea pig, which is a more susceptible animal.

Dr. Leudeking believes that we have but two diseases that may to-day be discussed as amenable to serum-therapy, namely, tetanus and diphtheria. With reference to the former the literature contains a number of reports of cures. Krieger cites five cases of recovery, but we have the word of Behring and of Roux to the effect that, although it is easily obtained and exhibits its preventive action with marvelous force, in practice it has not justified expectations. Of 553 cases of diphtheria, 303 were injected with serum and developed a mortality of 13.2 per cent. Two hundred and thirty were not so treated, causing a mortality of 47.8 per cent.

#### ETIOLOGY OF SOME HYSTERICAL MANIFESTATIONS, WITH REPORT OF A CASE TREATED BY HYPNOTISM.

This paper was read by DR. HUGH T. PATRICK, of Chicago. A point made by the author in the etiology of hysterical manifestations was that they are frequently the result of a subconscious imperative conception which slowly or rapidly develops from sensory or psychic impressions. The case was a unique one combining hysterical amaurosis of both eyes with hysterical pseudo-meningitis. The symptoms developed rapidly following an ophthalmic migraine, the pain and scintillating scotoma being the etiologic factors. This connection of cause and effect was distinctly shown during the recovery of the patient, and particularly by means of hypnotism. The hypnotism in this case, besides throwing light upon the processes involved in the generation of the symptoms, was a valuable diagnostic and therapeutic aid. Regarding hypnotism, Dr. Patrick insisted that there is no such thing as the hypnotic power as ordinarily understood,

but that in every case the subject in reality hypnotizes himself; that is, that hypnosis is always a subjective phenomenon. The ordinary *modus operandi* of inducing hypnosis was described and illustrated.

(To be continued.)

### Connecticut State Medical Society.

The one hundred and third annual meeting of the Connecticut Medical Society was held at Hartford, Conn., in Jewell Hall. The Fellows of the Society met at 2 o'clock. There are five Fellows from each county of the State with the exception of Tolland County, which has only three representatives. The meeting was presided over by President FRANCIS N. BRAMAN, of New London. The address of the President reviewed the efforts of the medical profession in 1763 to obtain from the Colonial Assembly an act regulating the practice of medicine. This and subsequent efforts failed, until the Legislature of 1893 passed the medical practice act, under which the State is now experimentally progressing. The act had brought about a more popular interest in medical practice, and the wisdom of the Legislature in passing the act was apparent. The President recommended that the office of county reporter be abolished and that a member from each county be appointed to act as a general committee to do the work now assigned to the reporter, the members to be Fellows of the society. The address was referred to a committee of three and its recommendations were indorsed and laid upon the table for action next year, as they involve an amendment of the by-laws.

The Committee on Nomination of Essayists reported: On Medicine, Max Mailhouse of New Haven, Chas. B. Graves of New London; on Surgery, W. H. Carmalt of New Haven, Harmon G. Howe of Hartford, and they were appointed. Honorary members proposed, to be voted upon at the next annual meeting, were: T. M. Prudden of New York, W. W. Keen of Philadelphia, and T. G. Thomas of New York.

The Committee on Medical Examinations reported an amendment to the present law, requiring three sessions for examinations to be held each year, in March, July and November, instead of monthly, as now. The report was referred to the committee on legislation.

The Committee on Nominations reported the following list, which was adopted: President, Seth Hill of Stepney; Vice-President, Rienzi Robinson of Danielsonville; Assistant Secretary, Julian La Pierre of Norwich; Treasurer, W. W. Knight of Hartford. Committee on matters of interest to the profession in the State, C. S. Rodman of Waterbury; A. E. Abrams of Hartford; R. W. Kimball of Norwich. Committee on publication, W. H. Donaldson of Fairfield. Committee on anniversary, C. P. Lindsley, M. C. O'Connor and F. H. Wheeler of New Haven. Dissertator, S. B. Childs of Hartford; alternate dissertator, Arthur N. Alling of New Haven. Delegates to the AMERICAN MEDICAL ASSOCIATION: A. E. Abrams of Hartford; F. H. Wiggin of Litchfield; Nathaniel Hibbard of Danielsonville; H. E. Smith of New Haven; L. B. Almy of Norwich; John E. Loveland of Middletown; G. A. Shelton of Shelton; Frederick Gilnack of Rockville; Robert Lawler of Bridgeport; Ralph A. Goodpin of Thomaston; E. P. Douglas of Groton; E. W. Pierce of Meriden. Maine Medical Society, P. H. Ingalls of Hartford; W. W. Hawkes of New Haven. New Hampshire Medical Society, F. W. Simpson of Hartford; J. B. Kent of Putnam. Vermont Medical Society, E. F. Davis of Ellington; Carl E. Munger of Waterbury; George N. Lawson of Middle Haddam. Massachusetts Medical Society, D. A. Cleveland of Middletown; M. Van B. Dunham of Greenfield Hill. Rhode Island Medical Society, T. D. Crothers of Hartford; F. E. Guild of Windham; E. H. Davis of Plainfield. New Jersey Medical Society, H. O. Allen of Broad Brook; F. W. Wright of New Haven. New York Medical Society, William H. Carmalt of New Haven; J. R. Topping of Bridgeport; A. E. Abrams of Hartford. Member of committee on medical examination, J. F. Calef of Middletown.

The necrology during the year included the names of Drs. H. S. Wildman, N. J. Hanmer and George C. Gay of Waterbury; W. A. M. Wainwright of Hartford, and Stephen G. Risley of Rockville. The honorary members who died dur-

ing the past year were Dr. Oliver Wendell Holmes of Boston, and Dr. George Chandler of Worcester, Mass.

In the evening, Dr. James Campbell, President of the Hartford Board of Health, gave a reception to the members of the society at his residence, 34 Congress Street.

The exercises the second day were as follows:

Annual report of the Secretary, N. E. Wordin, Bridgeport; reception of delegates from other State societies.

Vermont State Medical Society—J. M. Clarke, Burlington; Lyman Rogers, Bennington.

Massachusetts Medical Society—T. F. Breck, Springfield; Albert Wood, Worcester.

Medical Society of New Jersey—J. A. Exton, Arlington.

Medical Society of New York—L. Duncan Bulkley, New York; Reynold Webb Wilcox, New York.

Reports from delegates to other societies:

To the AMERICAN MEDICAL ASSOCIATION, San Francisco, 1894, Gould A. Shelton, Joseph E. Root, Edwin B. Lyon.

Baltimore, 1895, Alvin E. Abrams, Chas. S. Rodman, Max Mailhouse, Geo. R. Shepherd, Fred'k Schavoir, Loren T. Day, Frederick M. Wilson.

To the Maine State Medical Association, T. Morton Hills, Thomas M. Bull, M. V. B. Dunham.

To the New Hampshire Medical Association, Theodore R. Parker, Leonard B. Almy.

To the Vermont State Medical Society, George C. Bailey, O. J. D. Hughes.

To the Massachusetts Medical Society, D. A. Cleaveland, J. J. Morrissey.

To the Rhode Island State Medical Society, Charles E. Brayton, Henry B. Plunkett.

To the New York State Medical Association, Edward H. Welch, Frederick S. Smith.

To the Medical Society of New Jersey, Max Mailhouse, Frederick B. Baker, William V. Willson.

Report of committee on matters of public interest in the State:

Typhoid Fever—Irving W. Lyon, Hartford; Perforation in Enteric Fever—its Surgical Treatment, Frederick H. Wiggin, Litchfield; Notes of an Epidemic of Typhoid Fever, at South Glastonbury, Charles G. Rankin; The Treatment of Typhoid Fever at the Hartford Hospital, Joseph B. Hall, Hartford; A Brief History of Serum-therapy, Arthur J. Wolff, Hartford.

The Use of Diphtheria Antitoxin in Connecticut—Irving W. Lyon, Hartford; Report of the Progress of Medicine, Elbridge W. Pierce, Meriden, Everett J. McKnight, Hartford; Report on the Progress of Surgery, Chas. C. Godfrey, Bridgeport; L. W. Bacon, Jr., New Haven; Dissertation, Senile Cataract; one hundred cases. Comment, Frederick M. Wilson, Bridgeport.

At 12 M. the President's Address, Medical Sociology.

The afternoon session began at 1:30 P.M. The first paper was on Pneumonia and the Treatment of its First Stage by Stimulation, by William J. Tracy, Norwalk, followed by Tetanus, Edwin B. Lyon, New Britain; The Modern Management of Natural Labor, Henry Fleischner, New Haven, Benjamin A. Cheney, New Haven; Endometritis; its Surgical Treatment, Frederick Schavoir, Stamford; The Eye and Diseases to which Eye Symptoms Point, Arthur N. Alling, New Haven; The Errors of Refraction found in Four Thousand Eyes, Harry S. Miles, Bridgeport; Cerebral Thrombosis, Gustavus Eliot, New Haven; The Morphin Habit, John W. Wright, Bridgeport; Simple Meningitis, Max Mailhouse, New Haven; Cerebro-Spinal Meningitis, N. Nickerson, Meriden; Tubercular Meningitis, Stephen J. Maher, New Haven; A Case of Acute General Miliary Tuberculosis, of so-called Typhoid Form. Autopsy, James M. Keniston, Middletown; Modern Improvements in the Treatment of Diseases of the Skin, R. A. McDowell, New Haven; The Localization of Intestinal Obstruction; Illustrated by Three Cases, W. S. MacLaren, Litchfield; Observations on Operations for radical cure of Hernia, with report of cases, George C. Jarvis, Hartford; Observations on Appendicitis with report of Operations, Charles E. Taft, Hartford; The Diagnosis and non-operative Treatment of Appendicitis, John F. Dowling, Enfield; Fracture of the Kneepan, James K. Mason, Suffield; Public Hygiene, Lucy C. Peckham, New Haven; Defense of Public Health Boards, Frank W. Wright, New Haven; The Therapeutic Value of Mountain Forests, Charles D. Alton, Hartford; The Inebriety of Insanity from a Medico-Legal Point of View, Thomas D. Crothers, Hartford; A Case of Utero-vesico-vaginal Fistula, with successful Operation, George C. Jarvis, Hartford.

The annual dinner was served at the Hartford Hotel in the evening.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, JUNE 1, 1895.

TO THE YOUNG DOCTORS OF 1895.

"Practice and experience are of the greatest moment in arts; and there is no kind of occupation in which men may not learn by their abortive attempts."—COLUMELLA.

The schools have turned out this year an unusually large number of physicians. Where they will all go? what will they all do? and how many will succeed in reaching a high professional level? are questions that can only be answered by speculation. The medical statistician assures us, with the blunt rudeness of a mathematical slugger, that such a percentage die during the first year, that so many grow weary, and engage in other pursuits within a twelvemonth, or within two years at most, and the remainder, say 75 per cent. remain in the profession to work, and worry, and win success or failure as best they may.

To this last class we wish to indite a few words, although at a venture we presume they must have had a vast deal of advice in the semestre just closed.

We urge the young doctor to lose no time in joining the local medical society where he casts his lot. The men composing it may not be exactly to his mind, they may to outward view lack even some of the refinements of society, they may not care for them, they may have fallen distinctly below the level of the average knowledge of the times. But we advise the young doctor to pay attention and watch these wise old practitioners, for experience is a wonderful teacher, and many times he may learn very much from those he now thinks so far behind in pathology and laboratory lore.

Sometimes you may feel hurt at being treated like a raw recruit by these veterans, but you must remember that like all veterans they will be with you when you win your spurs, in society debate, or at the

bedside, and in proportion as you demonstrate your ability, their doubt of you will disappear. One thought will, we think, serve to give you a little closer relation with the old fellows, and that is that each one says to himself when he meets you, at the society or elsewhere: "Ah, if I were only young again like that young man! With the knowledge of the world, of men, of material things, that I have acquired, and his modern laboratory technique, what could I not accomplish in the average life time that is before him."

Be guided, then, by the voice of experience in all things not controverted by recent facts, and try yourself to become that ideal being the old doctor would be, had he only your growth and recent knowledge to add to his tact and *savoir faire*. Watch him closely! he knows men as open books; he knows how to manage and control them; he knows when to smile and when to be grave. He has learned his community; he knows what he can do without offense, and how best to acquire its good will. He knows best how to set forth the knowledge he has to its best advantage. Take all you can of his method, it is the result of experience, and pay him that deference when you meet him, that you yourself would like to receive from the classman of 1945 freshly filled with the new doctrines of which you will have only heard through your journal.

EURIPIDES lamented, "Alas! why is it not permitted to mortals twice to be young, and thence return once more to old age? For in our domestic affairs if aught be ill conducted, we put it right by after thought, but we have not this power over life. If we could be twice young, twice old, when we made a mistake, having twofold life, we could correct it."

The story of the Wandering Jew as retold by WALLACE in the "Prince of India," shows how much superior to every other man was that mysterious one who renewed his youth every one hundred years, and with it retained all the knowledge he had acquired during each centennium, and this leads us to advise our young doctor of 1895 to cultivate and conciliate his older colleagues, so that he himself may convey their general stock of information, in continuity with his own, to the profession of the future.

THE DUAL BRAIN.

The theory of duality of the brain as maintained by HOLLAND and WIGAN, and later by BROWN-SEQUARD and others, is one in regard to which most physicians probably hold themselves uncommitted, as they are hardly ready to admit it as proved that the two hemispheres can act to any considerable extent independently of each other. Clinical observations such as would be of value in determining whether such independent action is possible are rare, and those that seem to point that way have generally

been more or less incomplete and unsatisfactory. A recent observation by DR. L. C. BRUCE (*Brain*, spring, 1895), is therefore of special interest, as it comes from one who may be presumed to be a competent observer, and it is published in one of the highest grade medical periodicals of our time.

The patient was under observation continuously for three months up to the time of the report. In one stage he was demented, left-handed and talked only Welsh and gibberish; in the other he was fairly intelligent, but maniacally mischievous, right-handed and talked English, but understood and could converse also in Welsh. In an intermediate condition he was ambidextrous, and spoke a mixture of Welsh and English. In the English stage he remembered nothing of the Welsh stage, but had a perfect recollection of anything that had occurred in his previous English stages. His circulation and his bodily conditions generally were good in this phase, while in his demented state his mental and physical conditions were exactly the reverse. In his maniacal condition he wrote legibly with his right hand and produced mirror writing with his left; the specimens obtained with difficulty during the demented condition were illegible but were written with the left hand, from left to right. Thinking that the transition from one stage to another might be due to circulatory changes, DR. BRUCE took sphygmographic tracings in both conditions; in the maniacal or English stage the tracing revealed a full pulse of high tension, while in the other it had lower tension and less volume. Attempts were made to produce the two different stages artificially, but without success.

We have apparently in this observation, as DR. BRUCE remarks, a case of right hemispheric melancholia or dementia and of left hemispheric mania, occurring probably in an individual whose cerebral hemispheres acted more or less independently prior to the advent of the mental disorder or disorders, if we can assume the existence of such a condition. Or, as he suggests, only one lobe of the cerebrum, the left, is educated, and takes the greater part in mental action; the right functioning mainly in motion, sensation, etc., and playing but a very small part in intellection, would naturally show its derangement rather by the symptoms of dementia than those of mental exaltation.

It seems possible, moreover, that this condition of independent action of the hemispheres may be only exceptional, and that ordinarily, either originally or through education they always act together and share the same functions. It will be noted that in this case, though DR. BRUCE does not remark it, speech, which is generally regarded as a function of the speech center in the left hemisphere, was not altogether lost in this patient but was limited to Welsh, his native tongue. This, as far as it goes, would indicate that the left brain was not altogether inactive or that there

were bilateral speech centers, the former being perhaps the most probable of the two alternatives.

The case is an interesting one, not only as regards its bearing on the question of the duality of the brain, but also as suggesting possibilities from the study of the cases of circular insanity in our asylums generally. It may be that a closer observation of such patients would reveal other more or less similar instances, in which a marked predominance of one or the other cerebral hemisphere might be seen in the different phases of the disorder. In such a way, it may be, alienists have a special field of physiologic and psychologic research that has been heretofore too little cultivated.

#### COURT-MARTIAL OF A NAVAL MEDICAL OFFICER.

The case of MEDICAL INSPECTOR KERSHNER, Fleet Surgeon of the North Atlantic Squadron, has lately attracted considerable attention. While in harbor at Kingston, Jamaica, a sick call was sent from a foreign merchant vessel to the *New York*, the flagship of the squadron. DR. KERSHNER declined to attend the case on the ground that it might be one of yellow fever, and that his first duty was to protect the men of the fleet from infection. The captain of the *New York* reported the refusal to the Admiral, who thereupon sent an account of the matter to the Navy Department. It is understood that the Surgeon-General sustained DR. KERSHNER in his action and that the Secretary of the Navy could find nothing in the Naval Regulations requiring medical officers to attend the sick of merchantmen in places where other medical attendance was available. Meanwhile a Court of Inquiry was convened on the *New York* to investigate the manner in which certain indorsements in the case got into the newspapers; and since then DR. KERSHNER has been tried by a court-martial at Brooklyn Navy Yard for violating Article 235, Naval Regulations, in giving to the press the said proceedings and for perjury in testifying under oath that he had not done so. It appears from the evidence given before the court-martial that the Doctor has been much disturbed by reflections on his professional and private character, to-wit, that he was lacking in humanity, timorous, etc., made by the Admiral on certain correspondence sent to the Navy Department concerning the affair, and that he had written to SURGEON-GENERAL TRYON and to MEDICAL DIRECTOR BLOODGOOD asking for their advice under the conditions then affecting him. His counsel held that there could be no offense in thus consulting his superior in the Medical Department as it was customary for medical officers when in difficulties to write such letters to their friends in the Service and particularly to the Surgeon-General. In denying before the Court of Inquiry that he had furnished an official account of the matter to any one but the

Surgeon-General he has not regarded his letter to DR. BLOODGOOD as coming within the scope of the query, which had a reference to copies furnished with a view to publication. The official report of the proceedings of the court-martial are now before the Department, but the finding at this writing has not been made known.

In the JOURNAL of March 16, we indicated the need of a re-organization of the Navy Medical Department, to give energy to its present membership and enable it to fill its vacancies. We dwelt mainly on the objectionable features of the Service as presented to young officers, but it will be seen from DR. KERSHNER's case that objectionable features are not absent from the service of officers even when they attain the higher grades. The publicity given to this matter in the daily press will not tend to induce young men to enter the Naval Medical Service. There are now twelve vacancies in the Corps, and perhaps it would be a good thing for the Corps if it were found that these vacancies could not be filled. The medical officers of the Navy should in all respects be on the same footing and have the same consideration as their confrères in the Army.

#### THE SUCCULENT STRAWBERRY.

The season of the strawberry is now upon us. This berry in America is our earliest and latest fruit, for it is now produced in gardens on the Atlantic coast all the way from Florida to New Brunswick; in abundance in mid-season the entire length of the Mississippi Valley, and in great profusion on the Pacific coast.

One of the JOURNAL's young men last week in an excellent article on the social status of physicians, credited the well-known phrase about the strawberry to SIDNEY SMITH, which was too generous to SMITH, for it was a physician DR. WM. BUTLER (d. 1621) who first said that "doubtless God could have made a better berry, but doubtless God never did." BARTLETT says this first appeared in the second edition of WALTON's "Angler," 1655, and further quotes ROGER WILLIAMS in his "Key into the Language of America," 1643, p. 98, as saying: "One of the chiefest doctors of England was wont to say, that God could have made, but God never did make, a better berry."

In SHAKESPEARE's time the strawberry was held in high esteem. RICHARD III. says to Ely: "My lord of Ely, when I was last in Holborn, I saw good strawberries in your garden there; I do beseech you send for some of them." But the strawberry was an ill-favored token for DESDEMONA, for the handkerchief which IAGO gave OTHELLO to whet his jealousy had strawberry spots.

SIR JOHN SINCLAIR says:<sup>1</sup> "In regard to strawberries it is impossible to say too much in favor of

that fragrant, cooling and wholesome article. There are various modes of eating them, but with milk and cream is generally accounted the most agreeable, and is found to lessen in the stomach, the activity of the acid they contain. Strawberries are very wholesome. They tend to promote all the evacuations, and are laxative without inducing any apparently weakening efforts; they are also supposed to possess qualities unfavorable to stony concretions. The wild strawberry has the most agreeable flavor, and is perhaps the best of the whole species."

BEDDOE's "Hygeia," vol. II, essay VIII, p. 64 says: "To persons with weak digestion, the addition of a meal from the garden, to one from the kitchen is in the highest degree pernicious." From this it appears that as there are two sides to almost every story, so here a little investigation shows that not everybody may eat raw strawberries with impunity.

That interesting volume, *Le Cuisinier et le Médecin*, Paris, 1855, says: "Horticulture has marvellously developed the size of this fruit, without damage to the exquisite delicacy of its taste. The fruit is refreshing and a little laxative; it is not well received by all stomachs, because it is hard and cold. Convalescents should abstain from it, and those with disease of the stomach. The berries are eaten ordinarily raw; with sugar; with red wine, Madeira or Frontignan, etc. They may be also eaten with cream; but then they are very indigestible."

FAZIO (*Trattato d'igiene, Napoli*, 1887, p. 763) gives an analysis of the strawberry from KÖNIG:

Water . . . . .	87.66
Sugar . . . . .	6.28
Cellulose (from seeds) . . . . .	2.32
Nitrogenous substances . . . . .	1.07
Free acid . . . . .	.93
Non-nitrog. substance . . . . .	.48
Ash and remainder . . . . .	.81

An interesting case of alleged poisoning by strawberries will be found in the *American Journal Medical Sciences*, N. S., 1851, vol. xx, p. 363.

The cooking of the berry makes it one of the most digestible of all table fruits, and while by no means do we object to the delicate flavor of the fruit as it is picked, yet the difficulty must be admitted of having the fruit placed on the table raw, and yet of exactly that degree of ripeness that allows its highest degree of digestibility. As the berry is generally sold in the market, there is such a wide variation between the greenest and the ripest, that only proper cooking can make a uniformly pleasant and digestible dish.

#### THE OHIO STATE MEDICAL SOCIETY.

The semi-centennial meeting in Columbus, May 15-17, was an indication of decided progress in the affairs and influence of the society. Nearly five hundred physicians attended, most of them members. One hundred new members were admitted, making

<sup>1</sup> The Code of Health and Longevity, etc., etc. Edinburgh, 1807. Vol. I, p. 299.

the total permanent membership about eight hundred and twenty-five.

The program contained a lecture by JUDSON DALAND on malaria, illustrated by lantern slides. The Doctor was elected an honorary member of the society. Two alleged leprosy cases were exhibited by DR. J. G. MCDOUGAL. These cases are quite distinctly an Ohio production, adding to the interest in them. We shall print this paper with the photographs in an early number of the JOURNAL.

Other notable features of the sessions were an elaborate presentation of the status of the treatment of diphtheria from different parts of the State by DRS. HOWARD and OHLMACHER, of Cleveland; CASE, of Ashtabula; MOORE, of Columbus; EICHBERG, of Cincinnati. An able paper was presented on hot-water bath treatment of lobar pneumonia, by DR. JOS. EICHBERG, of Cincinnati; and one on typhoid fever by J. E. WOODBRIDGE, of Youngstown.

One of the most important features was the organization of a committee on medical legislation based on county representation, and the appropriation of \$500 to begin their work.

Ethical questions were decided, placing the society unequivocally in the list of staunch supporters of the Code of the AMERICAN MEDICAL ASSOCIATION.

DR. DAN. MILLIKIN, of Hamilton, was elected President; DRS. J. H. GOSS, of Lancaster, W. H. HUMISTON, of Cleveland, JNO. A. MURPHY, of Cincinnati, B. M. RICKETTS, of Cincinnati, Vice-Presidents. DR. THOS. HUBBARD, of Toledo, Secretary; DR. H. M. W. MOORE, of Columbus, Assistant Secretary; DR. JAS. A. DUNCAN, of Toledo, Treasurer.

The next meeting will be held in Columbus, May 27, 28, 29, 1896.

#### A BACTERIOLOGIC CONVENTION.

The JOURNAL of April 27 gave notice of the organization of a coöperative bacteriologic investigation by the committee on water supplies of the American Public Health Association, and of the difficulties encountered by the committee in drawing up a scheme of laboratory methods for use in the investigation.

We now invite the attention of boards of health, State and municipal, to the call of the committee for a convention in the Academy of Medicine, New York City, on June 21 next. We trust that the laboratories of each board will be represented at the meeting, to aid in making its results give accurate expression to the experience of American bacteriologists on the points at issue. Collegiate institutions also are interested, as the subjects to be discussed by the convention are those of pure or scientific bacteriology irrespective of the practical work hereafter to be undertaken by the members of the committee.

The names of the bacteriologists who are to open the discussion of the various points, give assurance of the most advanced thought in each direction. We print the call of the committee in another column.

#### TO THE NEW MEMBERS.

The Editor is in receipt of several letters inquiring why the new members do not receive the JOURNAL. We have to say that we have been unable, up to this time, to obtain a list of new members from either the Permanent Secretary or the Treasurer. The gentlemen who joined the ASSOCIATION at the last meeting will have to wait until the Treasurer's office furnishes the list. In the meantime we have *estimated* the number of new members at 300 and are storing up that number of extra copies.

#### SOCIETY NEWS.

**Call for a Bacteriologic Convention.**—The following, dated May 21, 1895, has been issued by the Committee on Water Supply of the American Public Health Association:

*Sir:*—Your presence is earnestly solicited at a Convention of Bacteriologists to be held upon Friday and Saturday, June 21 and 22, 1895, in the Academy of Medicine, New York City.

The Committee of the American Public Health Association appointed to determine the possibility of establishing coöperative investigation into the bacteriology of American waters was from the outset impressed strongly by the fact that the chaos at present existing with regard to the bacteriology of water is essentially due to want of exactitude in the details of research and more especially to the absence of standard and generally accepted methods. The replies received to letters circulated by the committee and addressed to the leading laboratories of the United States and of Canada, have indicated a general concurrence in the views therein expressed and have shown how strong is the consensus of the opinion that the time has come to attempt to establish the methods of systematic bacteriology upon a basis more nearly resembling that of an exact science. The proposal that a conference be held has met with a most willing response on the part not only of those representing State, provincial and municipal boards of health, and connected with the water supplies of large public bodies, but also of those interested in every branch of bacteriology. The fact is fully appreciated that it is in the highest degree desirable that the methods employed by any one worker in any branch of systematic bacteriology should be such as others can be expected also to repeat with precision and should be such as gain the approval of the majority. A satisfactory settlement of the questions given below is conceded by experienced bacteriologists to be necessary for substantial progress in the future, not only in the field of pure bacteriology, but also along those lines in which its application plays a prominent part—in the bacteriology of water, air, soil, milk, etc., and in that of disease. The conference will therefore be an attempt to establish some common ground-plan for systematic work in bacteriology in general, in the bacteriology of American waters in particular.

The committee is authorized to announce at this date that discussion on the points at issue will be opened as follows:

1. What method shall be followed in neutralizing all media, and what standard degrees of reaction shall be adopted?

The discussion upon this and upon questions 3 and 8 will be opened by G. W. Fuller, S.B., Biologist in charge of the Lawrence Experimental Station of the State Board of Health, Massachusetts, who will communicate the results obtained by the committee upon these points.

2. What effects upon species differentiation, are produced by the ordinary differences in composition of peptone, meat juice, gelatine, etc. W. T. Sedgwick, Ph. D., Biologist to the State Board of Health, Massachusetts.

3. What media shall be used for all species differentiation, and how shall they be uniformly prepared?

4. What shall be the medium for and the conditions of, the stock culture from which all media are seeded? E. O. Jordan, Ph. D., University of Chicago.

5. What shall be the systematic detailed method to be followed in observing the results of cultures and the manner of recording them? W. T. Sedgwick, Ph. D.

6. What method shall be adopted by which full benefit may be derived from morphologic characteristics? Dr. T. M.

Cheesman, Laboratory of College of Physicians and Surgeons, New York.

7. What tests shall be used for separating bacteria into clearly marked groups? Wyatt G. Johnston, M.D., Bacteriologist to the Board of Health of the Province of Quebec.

8. What shall be the method followed in determining the relation of bacteria to temperature? Geo. M. Sternberg, Surgeon-General, U. S. A.

9. What special methods are of value in the isolation of pathogenic bacteria in water? A. C. Abbott, M.D., University Laboratory of Hygiene, Philadelphia, Pa.; E. O. Jordan, Ph.D., University of Chicago.

10. What shall be the method of procedure in determining the pathogenesis of bacteria found in water? W. H. Welch, M.D., Johns Hopkins University, and Victor C. Vaughan, M.D., University of Michigan, Ann Arbor.

11. How is variability of species to be regarded? J. G. Adami, M.D., McGill University, Montreal.

12. What new methods can be suggested for the separation of bacteria into groups and for the identification of species? J. J. MacKenzie, Bacteriologist to the Board of Health of the Province of Ontario.

Communications in connection with these subjects have also been promised by several others, including: Thos. B. Carpenter, M.D., Health Department, Buffalo, N. Y.; H. C. Ernest, Harvard Medical School; C. J. Foote, Yale University; H. L. Russell, Agricultural Experiment Station, University of Wisconsin; C. Smart, Major and Surgeon, U. S. Army; E. B. Shuttleworth, University of Trinity College, Toronto.

The full program giving detailed order of proceedings will be issued early in June. The replies already received by the committee have assured us that the bacteriologic departments of many State, provincial and municipal boards of health will be represented at the conference, as also the principal universities of the United States and Canada. The conference will thus be a peculiarly representative assembly of bacteriologists. The importance of the subjects to be discussed leads us to hope that you will be present or be represented by a delegate. The convention will be called to order at 10 A.M., on Friday, June 21.

Yours faithfully,

CHARLES SMART,  
J. GEORGE ADAMI,  
GEORGE W. FULLER,  
WYATT G. JOHNSTON.

## NECROLOGY.

CARL THIERSCH, M.D., the eminent German surgeon, died on the 28th ult. at Leipzig, aged 73 years. He was a native of Bavaria and was educated at the University of Munich, graduating in 1846. He afterward resided successively in Berlin, Vienna and Paris. He was a frequent contributor to the literature of his profession, and the system of skin-grafting which he introduced is now generally adopted by surgeons throughout the world. He also wrote upon maxillary necrosis from phosphorus and upon Listerian methods in surgery.

GEORGE A. PERKINS, M.D., who died in Salem, Mass., on May 18, was a man of mark and of varied experience. He was born in Salem, Oct. 15, 1813, and received his early education in the local schools. When he was 20 years old he engaged as a wood-engraver with a New York publishing house and so continued until 1836. After his return from Africa, whither he went as an Episcopalian missionary, he entered Harvard University Medical Department. He took his degree there in 1844, and soon afterward returned to Fishtown, in West Africa, to serve as a medical missionary. In 1850 he returned to his native town and at the age of 37 began life anew in the pursuit of private practice, and not long after began with others to agitate for the formation of the Salem Hospital. That institution, of which Dr. Perkins was consulting physician at a recent date, was launched in 1874. He was Post Surgeon at Forts Lee and Pickering from December, 1863, to May, 1865, and for a long time physician at the Salem House of Correction and the almshouse. He was

widely known as an expert microscopist and chemist. He was a member of the Salem School Committee for fifteen years, and of the Essex Institute, Massachusetts Medical Society, New England Historical and Genealogical Society, Starr King Lodge of Free Masons, Salem Athenæum, and the Tabernacle Church. He was a member of the original staff of the Salem Hospital.

HENRY JOSEPH HESSE, M.D., formerly a coroner of Kings County, N. Y., died May 19 at his home in Brooklyn in the forty-second year of his age. He was born in New York of German parents, and in 1876 received his degree in medicine from the Long Island College Hospital. He began practice at once in the eastern district of the city of Brooklyn, where he continued during his professional life. The cause of his death was erysipelas, an attack of two weeks' duration followed about a week before death by a pneumonia.

RICHARD DUBOIS TRAVER, M.D., of Troy, N. Y., died suddenly May 17, from a poisonous dose of chloral. It is stated that he mistook the latter drug for Epsom salts, and immediately upon swallowing the solution he recognized that he had made a mistake. He busied himself for some time in his own office consulting his books for an antidote for the poison. He thus lost valuable time, and when it was too late went to the office of a neighboring physician. He there secured help, but it was unavailing, for death ensued not long afterward. He was an alumnus of the St. Louis Medical College in 1864, and of Bellevue College in 1867. He was eminent in his county organizations, having been president of his medical society. He was a member of his State Association and a veteran of the Rebellion, and also served in the 8th United States heavy artillery and the 7th Minnesota Infantry. He was also a prominent Mason. The Doctor was 56 years of age and had resided in Troy about twenty years.

PROF. GUSTAV HIRSCHFELD, of the University of Königsberg, died in Wiesbaden on April 20, after a long and heroic fight with cancer. In the vain hope of obtaining relief he even came to America, and became an inmate of the New York Cancer Hospital for a time. In his great and minute knowledge of Asia Minor and all matters pertaining thereto he was easily without a peer. He was a Jew, gifted with keenness of intellect and charm of manner as are few men. He died in the very prime of manhood.—*The Independent*.

W. MALLET PREVOST, M.D. A press dispatch announces the decease of the above named physician, late of Philadelphia, as having occurred May 13, at Fresnillo, Mexico.

J. F. SIMMONS, M.D., of Houston, Texas, is reported by telegraph to have been fatally shot by Robert Owen. It is stated that the physician was at the house of his assailant, having been summoned there to see a sick child. The assailant also shot his wife, but not fatally; he then committed suicide.

WILLIAM M. THORNTON, M.D., of Boston, Mass., May 23, aged 49.—Robert L. Mintie, M.D., of Chicago, May 21, aged 45.—Mary H. Thompson, M.D., of Chicago, May 21, aged 62.—Ezra Pascal Allen, M.D., of Athens, Pa., May 21, aged 74.—W. L. Blickhan, M.D., of St. Louis, May 20, aged 33, superintendent of the St. Louis City Hospital.—J. D. Carter, M.D., of Knoxville, Tenn., May 19.—Jay Guy Lewis, M.D., of Sparta, Ore., May 12.—S. W. Beck, M.D., of Washington, Ind., May 16, aged 78.—James H. Fore, M.D., of Baltimore, May 16.—Chauncey R. Fairchild, M.D., of Kansas City, Mo., May 16, aged 77.—David Youngman, M.D., of Boston, Mass., May 11, aged 78.—J. J. McManus, M.D., of Rutland, Vt., May 15.—G. S. Butler, M.D., of Edgefield, S. C., April 28.—Fred. Barrett, M.D., of Duluth, May 17.—J. R. Flowers, M.D., of Columbus, Ohio, aged 59.

## PUBLIC HEALTH.

**The Food of the Black Belt.**—The Department of Agriculture at Washington has established a department for research concerning the quality and quantity of food-stuffs consumed by the colored population in the black belt of our Southern States. It is located at the Tuskegee Institute, Tuskegee, Ala.

**Vigilance at Quarantine.**—The *Mexican Prince*, from Rio de Janeiro at New York quarantine May 25, was detained by Health Officer Doty to investigate the cause of death of a passenger during the voyage. The death was presumably due to consumption, but as there is yellow fever at Rio, Dr. Doty deemed it advisable to make careful inquiry.

**The Plague is Quarantinable.**—Under the last Regulations of the Treasury Department the diseases to be quarantined at ports of entry are cholera, yellow fever, typhus, variola, leprosy and the plague. The latter disease is now again rampant at Amoy, China, with fifteen deaths from that cause daily; so that the Pacific coast will have to be on the *qui vive*.

**Making Vaccination Odious.**—If it be true, as reported, that two physicians of the New York City Board of Health recently vaccinated 1,000 children in nine hours, that is a fraction over 18 a minute, the following comment of the Bangor (Me.) *Commercial* is just and timely: "To say that vaccination could be properly performed at this reckless, break-neck rate is simply ridiculous. But possibly these eminent practitioners wanted to give the impression that vaccination is a humbug and did their work with that end in view."

**Janitors' Homes in Public Schools.**—A case of diphtheria having occurred in the family of the janitor of public school No. 89, in a New York City up-town district, the school was closed and 2,000 pupils will take an unexpected vacation. These cases nearly always beget a certain amount of friction between health officers and the Board of Education. The short way out of it seems to be to have the janitors live near by rather than in the school edifice. The loss to the pupils of their enforced exclusion from school privileges, to say nothing of the possibly greater dangers of infection among the little folk, is not easily calculable. It is not infrequently through some species of favoritism that the janitor is crowded into a building—so that he can avoid rent-paying—which was never designed to have a family residence in the lower regions.

**Canned Horse.**—The suggestion in the *JOURNAL* of April 13, concerning the utilization as a food supply of the immense droves of wild horses in Oregon, Washington, Idaho and Montana, has developed the fact that some of the salmon cannery on the Pacific coast had already turned their attention in that direction. One firm has put "canned horse" on the San Francisco market where it has been served in restaurants. The local papers say the flesh resembles beef in appearance, and can not be told from it by taste. "The grain of the flesh is fine, and dozens of people have sampled the canned horse, and are unanimous in pronouncing it good, though there was not one of them but confessed to a prejudice against the eating of horseflesh." Another firm has organized at Portland, Oregon, for canning on a large scale; it has bought 6,000 horses at from \$1 to \$5 apiece and is contracting for great numbers, expecting to supply a palatable, nutritious flesh-food at one-quarter to one-half the price of beef. It only remains for the learned lexicographers to put a name to it; "horseflesh" obviously will not answer; it is too suggestive.

**Another Typhoid Epidemic.**—Out of a population of about forty thousand inhabitants, Lancaster, Pa., had at the close

of May not less than one hundred cases of typhoid fever under treatment, with an average of ten to twelve new cases reported daily. The water supply of the city is obtained from the Conestoga creek, a large stream which courses through the county and which supplies the city reservoirs. It is claimed that the Conestoga is polluted from various sources, so that its waters are a highly favorable culture medium for all forms of pathogenic bacteria. Reports say that the local board of health is using energetic efforts to check the spread of the disease and the State health authorities, who alone have power over the water courses, will take measures to remove the cause of the epidemic. Already there have been several deaths, and some well-known citizens are prostrated by the disease.

**Persistence of Diphtheria Contagion.**—At a recent séance of the Medical Society of the Paris Hospitals, MM. Sevestre and Méry communicated some extremely significant facts showing that the Löffler bacillus may persist in children who have been rapidly cured by the antidiphtheritic serum. This brings up the question, how long is it necessary to isolate diphtheritic children after disappearance of the false membrane and of the symptoms in general? They mention a case in which virulent inoculable bacilli were found forty days after removing the tracheal tube. Other observers have noticed a much longer duration, *e. g.*, Belfanti (*Reforma Medica*) reports a case of contagion after an interval of seven months. A bacteriologic examination is the only means of assuring us of the disappearance of the danger; but while this is easy in hospitals, it is difficult in family practice. We must not insist on too prolonged isolation in families with small means, where the children are numerous and the dwelling small. It seems that fifteen days' isolation after complete disappearance of the false membranes, when there are no more clinical symptoms, and especially when there is no more discharge from the nose, is sufficient. In cases of prolonged virulence for thirty or forty days, while this lasts it is advisable to continue the isolation as well as the irrigation of the mouth and nose.<sup>1</sup>

**Attacking Sanitary Merit.**—The usual biennial fight against Dr. Henry D. Baker, the able and useful Secretary of the Michigan State Board of Health, is on in the General Assembly of that State, and a legislative inquiry into the methods and value of the Board and of its Secretary was recently concluded. The *JOURNAL* is glad to note that the press of the State, generally, take an intelligent view of the situation, the *Detroit Journal* of a recent date characterizing the present attack as instigated by the "personal animus of two disgruntled ex-clerks," and asserting that, while the Board conclusively refuted every important charge, "the investigation has given most humiliating evidence of the ease with which small-minded men, smarting under fancied grievances, can pull the Legislature around by the nose. Dr. Baker declared that one clerk was insubordinate and the other lazy and incompetent. Their attacks on him were relative to small things, which may be found in any public office." In reviewing the work of the Board during the past years, in "stamping out" the communicable diseases and in investigating their causes with the view of finding means of prevention, our lay contemporary says: "The credit for the usefulness of the State Board of Health was very cheerfully accorded to Dr. Baker in a large measure by the present and former members of the Board, who testified before the committee. He is a broad man and has more administrative ability than is usually seen in men of science. He is not yet an old man, and Michigan can not afford to dispense with his services now." To which the *JOURNAL* would add that neither can the country at large nor sanitary interests generally afford to dispense with his services for very many years to come.

## ORIGINAL ARTICLES.

### HYDROTHERAPY IN FEVERS, ITS RATIONALE AND TECHNIQUE.

Read in the Section on Practice of Medicine, at the Forty-sixth  
Annual Meeting of the American Medical Association, at  
Baltimore, Md., May 7-10, 1895.

BY ALBERT H. BURR, Ph.B., M.D.

PHYSICIAN TO PROVIDENT HOSPITAL, CHICAGO, ILL.

In every febrile condition, whatever its specific cause, there is exhibited a complexity of abnormal physiologic activities, a reaction of the animal system dependent upon the essential properties of protoplasm and nerve energy. The most obvious of these disturbed functions common to all febrile conditions are: increased oxidation, elevation of temperature, increased though still inadequate elimination of waste products, increased frequency and weakened force of the respiratory and cardiac impulses, perverted metabolism and loss in muscular tone and neural vitality.

Heat energy in the healthy body is the result of chemic change in its proteids, fats and carbo-hydrates through processes of oxidation. Welch in his Cartwright Lectures, maintained that the production and dissipation of heat is kept in equilibrium in health by the direct control of a heat-regulating nervous system. He affirms that "fever producing agents act directly or indirectly upon this nervous mechanism which regulates the harmonious relations of heat loss and heat production." In like manner we may conclude that all the disturbances of physiologic functions manifested in the state we call fevers are, in reality, so many symptomatic expressions of a toxic derangement of neural resistance and neural control.

The efficiency of any measure instituted for the treatment of these functional disturbances will depend upon the reliability of our knowledge of the invading causes and the processes by which these disturbances are accomplished. All therapeutics aimed at symptoms or effects instead of seeking to remove or limit these causes where possible, or to reinforce neural resistance and control against them are certainly irrational and may be worse than useless. The search for specific remedies carried on for ages has brought to light but two that approach specific results in fevers. With all our increased knowledge of the special germs which produce each characteristic form of febrile disturbance, we are still unable to expel the invader and, with the exceptions noted above, the relentless warfare is continued until immunity is established on one hand, or, on the other, death ends the conflict. During these ages the battle has been waged against that chief symptom and bugbear, elevated temperature. The patient has been depleted by purgatives and venesection; he has been starved and sweated by turns; the nervous energy of his heart has been depressed by cardiac sedatives to lower his temperature. The introduction of

the coal-tar antipyretics marked the culmination of the antithermic craze. Experience has taught every teachable physician that only harm can come from artificial antipyretics. It has been demonstrated that they impair neural resistance and control, that they obtund nerve sensibility and retard metabolism and the elimination of normal waste and morbid products.

Pyrexia may be considered normal to every febrile disease. Indeed, it may be one of nature's conservative processes in the systemic reaction of protoplasm and nerve energy against the offending infection. It may be a useful ally in combating, limiting or destroying the invading microbe, just as inflammation through processes of reaction throws up its defensive walls to the enemy. If this be true, the normal temperature of any febrile affection can not be interfered with by direct artificial antipyretics without injury to the patient. Normal reduction of temperature must be secondary and a natural sequence to the limitation or removal of the trespassing cause.

The treatment of fevers by the cool bath is as old as the teachings of Hippocrates, and yet so new, by reason of the apathy of the profession and neglected study of its rationale, that even most medical teachers and writers of text-books seem to understand but imperfectly the scope of its physiologic actions and its therapeutic possibilities.

Hydrotherapy properly used in fevers is not hydrophathy, is not a panacea, is not primarily antipyretic, is no longer empiricism. The classical demonstrations of Winternitz, Voit and Schüller in Europe; of Baruch, Draper and Thayer in America, have clearly defined the basis of its physiologic action and placed it in the front rank of rational therapeutics. A brief summary of their investigations shows that the cardinal principles of the physiologic action of the cold bath in fevers depend:

1. On the physical properties, thermic and mechanical, of water itself acting directly as neural stimulants. Water absorbs heat and parts with it quickly. It may be applied in solid, liquid or gaseous form to the whole body or any part of it. Its application may be continuous or intermittent, alternating from hot to cold, or modified by any desired temperature or pressure. In short, we have always at command a most flexible agent with which to meet a wide range of indications.

2. On the susceptibility of the sympathetic nervous system to these stimulants and its control over the vascular and glandular organs of the body. This stimulative action takes place primarily on the cutaneous surface. The skin is a threefold organ, at once the richest in sensory nerves, the greatest in vascular expansion, and the largest in glandular supply of all the organs of the body. What a field for therapeutic operation! How easy of access and how

quick to respond! Every physician has noted the effects of the rapidly alternating cold and hot bath in resuscitating the asphyxiated newborn babe. No harm results to the delicate infant; no one charges cruelty when these extremes of thermic effects are thus employed. In syncope what can bring the flush to the pallid cheeks and reestablish respiration so quickly as a stimulating dash of cold water upon the face? In hysterical paroxysms how quickly the explosions of an unstable nervous condition give way to perfect control through tonicity imparted by the same mechanical and thermic effects of water. We need not multiply instances to show that the stimulating properties of water, appropriately used, are responded to by prompt and definite physiologic activities.

3. On the reflex action of the stimulated nerve centers, on (a), respiration; (b), circulation; (c), metabolism; (d), elimination; and (e), pyrexia.

(a.) Stimulation of respiratory centers is the first and immediate reflex action from the application of cold water to the cutaneous surfaces. Deep spasmodic inhalations take place and improved oxygenation of the blood is at once manifest.

(b.) Circulation is quickened by reaction on the cutaneous vascular system, which is heightened by friction. In this way the relaxed capillaries are given muscular tone and are successively emptied and filled by cutaneous massage. The impulses thus set up are conveyed throughout the whole vascular system, relieving stasis and organic congestion, and in conjunction with improved respiration stimulate the cardiac centers and a slower, steadier strengthened impulse of the heart is definitely established. The effect on the circulating medium itself is still more wonderful. Winternitz, at the International Congress at Rome last spring, gave the results of some recent investigations of thermic effects on the composition of the blood in health. He demonstrated that all applications of cold to the entire or greater portion of the surface of the body, when proper reaction was secured, led to three remarkable results, viz., an increase in the number of leucocytes, an increase in the percentage of hemoglobin and an increase in the specific gravity of the blood. Local applications of cold, followed by reaction, accomplished the same results in the local blood supply. This affords us now for the first time a rational instead of empirical basis for the employment of cold compresses and poultices.

Thayer, of Johns Hopkins, has shown that blood drawn from the lobe of the ear of a typhoid fever patient after a Brandt bath, had three times the number of leucocytes as blood drawn from the same source just previous to the bath. It is not credible that so great an increase in the number of leucocytes can take place by reproduction in so short a time, but it is probably accounted for by the increased activity of the circulation, under the stimulus of cold and friction which sweeps them from out-of-the-way places into the quickened circulation. (Baruch).

(c.) Metabolism, both constructive and destructive, is greatly promoted. This is a natural sequence of the improved blood supply carried to the glands and tissues. Schwann first employed the term to express the changes wrought by living cells upon substances coming in contact with them. This is constructive through nutrition and destructive through tissue change. The action of the leucocytes, may be

considered a form of destructive metabolism and takes place in the blood, glands or tissues wherever the toxins and microbes of fevers are found. The investigations of Vaughn and others show that the antitoxic and antiseptic effects of the blood are due to leucocytes and their nucleins derived from their cell contents. When leucocytosis was increased the antiseptic and antitoxic power of the blood was also increased. If, then, it is established that cold baths, under proper reaction, increase these leucocytes in the circulation even to threefold, then the destruction of microbial products must be wonderfully increased.

(d.) Elimination of toxic products through the emunctories is increased by the improved functional activity of all of these organs, as a result of increased pressure, and improved blood supply. Juergensen demonstrated that the specific gravity of the urine was increased after the cold baths through increase of urea. Roque and Weil demonstrated that the toxicity of the urine was increased sixfold after the Brandt baths in typhoid fever, while by the expectant plan of treatment it was only twofold, and when antipyretics of the coal tar series were used it was the same as or even less than that of normal urine. Liebermeister and Voit showed that cold baths in fevers greatly increased the elimination of carbon-dioxid by the lungs.

(e.) Pyrexia is a symptomatic expression of a toxic derangement of neural resistance and control. When the nerve centers begin to recover from the profound intoxication which has disturbed neurotic equilibrium, abnormal temperature begins to subside. Heat reduction, therefore, is a resultant of the combined effects of the cold baths on respiration, circulation, metabolism and elimination. It begins to approach the normal status in direct proportion to improvement in these physiologic processes, and is secondary and incidental to them. Nor is heat reduction due in any considerable degree to heat abstraction. If it were so the temperature would begin to rise again as soon as the cold applications were discontinued. On the contrary, I have observed time and again that the temperature continues to fall until it reaches the lowest point in one to one and a half hours after removal from the Brandt bath, in typhoid fever. By repeating the bath *pro renata*, as indicated by the toxic effects on the general condition of the patient, to which the temperature alone is not always an infallible guide, we can more safely and definitely enhance the resistance of vital forces against toxic agencies and promote their elimination than by any known symptomatic drug treatment. As the surgeon gives free and open drainage to the products of infection in a septic cavity so may the physician, by cold baths with reaction, favor the physiologic drainage of toxins from a body charged with thermogenic poisons. It is a mistake, and a generally prevalent one also for which our text-books are largely at fault, to regard the cold water treatment of fevers, especially that of Brandt in typhoid as an antipyretic measure chiefly. Hence resort is had to less troublesome but more dangerous means of reducing temperature. Pepper's System of Medicine, vol. 1, p. 327, says concerning the various applications of cold water in typhoid fever: "They all act in the same manner and depend for their efficacy upon their power of abstracting heat from the body and are useful just in proportion as they do this."<sup>1</sup>

<sup>1</sup> Pepper, Vol. 1, pp. 117-118, last edition, 1893: Undoubtedly, one of

Nothing can be more misleading. Brandt, who published his paper on "Hydrotherapy in Typhoid Fever," in 1861, made no such claim for his treatment. He attributed its benefits to the stimulative effects primarily with fall of temperature as a secondary result. Heat reduction in continued fevers *per se* is of little practical value. It is not heat but poison which is the disturbing element. Heat is a symptom, one of the effects of the operating toxemia. Heat reduction in itself can not eliminate toxins or destroy microbes, and all therapeutic measures used for antipyretic effects which do not limit or remove disturbing causes, are both unscientific and absolutely dangerous. Experiments just cited prove that artificial antipyretics are worse than useless, in that they retard toxin elimination.

Upon these deductions rest the claims of hydrotherapy as a rational and scientific treatment in fevers. If we have rightly interpreted the physiologic activities which are stimulated by the appropriate thermic and mechanical effects of water, then we have at hand an agent universally adaptable to the treatment of all thermogenic diseases. No known drug remedy can so quickly and definitely influence the functional activities of living cells in nerve, gland or muscle, or protoplasm itself, as water when appropriately used in fevers.

If clinical experience is the highest court of appeal in all therapeutic questions surely the evidence is overwhelming, and the medical profession of America must stand convinced of its truths, and convicted for its apathy towards so great a life saving measure. It is not the province of this paper to give the clinical evidences, statistics and opinions of eminent men who have had large experience with hydrotherapy in fevers. We refer to the latest editions of Strümpel, Hare, Osler and that most excellent little book, "Uses of Water in Modern Medicine" by Simon Baruch.

It is sufficient to say that in over one hundred thousand tabulated cases of expectant treatment of typhoid in hospitals, the mortality has been 21.8 per cent. With mixed treatment consisting of medicines and the cold bath, more or less fully carried out, the percentage of mortality has decreased just in proportion as efficient bath treatment predominated. Under strict cold bathing alone, in over three thousand cases a mortality is recorded of 1.8 per cent. Brandt reports 2,150 cases where this treatment was begun before the fifth day, without a single death.

It is conclusive that the earlier this treatment is instituted the more favorable the results. My own practice is not to wait for a diagnosis but to institute some appropriate bath for all fever patients at once. Nothing but good can come of it, no matter what the diagnosis, and in the event of typhoid everything is to be gained. Where the life of the patient is in jeopardy no unavoidable risks can be taken by the attendant, without censure.

#### TECHNIQUE.

The technique of hydrotherapy in fevers has been fully described and illustrated by the authors just cited, but apparent difficulty in carrying out proper measures in general practice has led the majority of

the most important indications which must be met in the great majority of cases of typhoid fever is that for reduction of temperature. A large proportion of this mortality (in typhoid) comes directly or indirectly from the baleful influences of the pyrexia. The only way in which this can be met safely and effectually is by the external use of cold water.

Flint: Of all therapeutic measures those directed toward the reduction of the fever take the first rank. Pp. 929, edition 1894.

the profession to believe it practicable in hospitals only. Accordingly halfway measures, like ablutions, spongings and cool packs are substituted. Measures which in no way meet the indications of the full bath. Others ignore bathing in any efficient form and still adhere to the expectant plan or to symptomatic medical treatment, with indifference to the old-time mortality.

The most efficient of all hydrotherapeutic measures

Fig. 1.—Frame folded.

in the treatment of fevers is the full bath. There are certain obstacles in the way of putting it into practical use, chief of which are:

1. Entire absence of, or imperfect facilities in, the home for giving the full bath.
2. Dangers and annoyance to the patient, from handling to and from the tub, in another room, or even at the bedside.
3. The exhaustive labor imposed on attendants.
4. The objections and prejudices of patient and friends to the discomfort of the plan as ordinarily carried out.

To overcome these by no means trifling objections

Fig. 2.—Frame open.

I have devised a portable folding tub for use in the bed of the patient, which I believe will commend itself at once for the ease with which it may be employed under all circumstances with the utmost comfort to the patient and attendants and prove a valuable addition to the technique of cold baths in fevers. It consists first, of a large rubber sheet with rings attached by elastic tapes near its margins; and of a crib-like wooden frame with fastenings along the outside of the lower rail, to hold the sheet when in use. This frame can be folded into a space two by three inches by eight feet long when not in use. The accessories are a three-quarter inch hose with a metal elbow for a siphon, a bath thermometer and a sponge of good size.

Fig. 3.—Tub complete, with siphon in operation.

In use, the sheet is first slipped under the patient and brought up over the pillow, and its edges tucked up alongside the body. The frame is then unfolded and placed down over the patient, pillow, rubber sheet and all. The edges of the sheet are now drawn up over the top rail of the crib and down the outside to the lower rail where it is held fast by its rings. This completes a light and perfect tub capable of holding twenty gallons of water, if desired, and capable of being emptied quickly by the large siphon.

The bath is now initiated with the patient resting

comfortably on his own mattress and pillow, with but slight disturbance. Any gradation of temperature from 90 degrees down to 65 degrees may be employed, or changed rapidly or slowly as desired, while friction over the entire body by constant rubbing is practiced for ten or fifteen minutes. The bath completed, the water is siphoned into tubs or buckets on the floor. Any excess is sponged up, the edges of the sheet are then unfastened and dropped inside the frame, which is lifted, folded and set away. The sheet may be slipped from under the patient or remain at will, with fresh linen over it, for the next bath.

The many advantages derived from this simple and comparatively inexpensive tub are so evident as to require no enumeration. Spongings or ablutions, however well done, can not take the place of tubbing. They are feeble substitutes and fall short of the chief effects of the full bath, viz.: the greater reflex stimulation with corresponding sequelæ engendered by the contact of cold water over the entire cutaneous surface. Cold packs preclude the constant chafing and friction over the whole body which is an essential feature of the full bath to maintain tonic reaction of the cutaneous circulation. These less rigorous methods, however, may serve to educate the patient in the beginning and lead up to the more effective full bath.

If one chooses to employ the graduated bath of Ziemssen, which consists in gradually reducing the temperature from 90 degrees to 72 degrees for half an hour with gentle friction, a plan much in favor at the Tübingen University clinics, or the prolonged warm bath of Dr. L. Riess of Berlin, which consists in immersing the patient in a bath at 88 degrees whenever rectal temperature reaches 102 degrees and continued through the day, or day and night if necessary, till temperature in rectum registers 100 degrees, then the comforts and utility of the tub here presented are still more manifest.

The day is at hand when the therapeutic resources of water no longer dictated by empiricism, but placed on a firm and rational basis should be mastered by every conscientious practitioner of the healing art. Until specific medications have become established, we must yield to the claims of one of its early apostles: "Febrifugum Magnum, or Common Water, the Best Cure for all Fevers." (Dr. Hancock, Lothbury, Eng., 1723).

#### DISCUSSION.

DR. DAVIS—I have been for a number of years a very hearty advocate for the use of the cold bath in typhoid fever. I do not believe, however, that it in any degree shortens the course of typhoid fever, but it does make the fever very much less dangerous, and contributes to the patient's comfort. It seems probable that the typhoid state, so-called, is the result of perverted metabolism. It therefore appears likely from the results that we get clinically by the use of cold baths that by their employment we are treating more the typhoid state than we are the typhoid infection. Hence we get a decided change in the appearance of our patients by the use of the cold bath. They lose the mental dullness, particularly if the bathing is begun very early, and we find our patients remaining cool-headed, with tongue and mouth moist; and there is an excretion of a moderate quantity of urine of a fair specific gravity. In regard to this apparatus, it is extremely convenient, without any question whatever, and deserves a very general and large use. For more than a dozen years I have constantly employed a rubber sheet, used as in this instance, placed under the patient lying in bed, and drawn well up over the pillow, and then water is applied with large sponges, so that a quantity accumulates around the patient. Dr. Burr's apparatus, however, makes it possible to give the full bath with just as little inconvenience as the method I have described.

DR. BORDER of Pittsburg, Pa.—In one of the principal hospitals in Pittsburg we have made use of the cold bath treatment, and clinical reports are very favorable. However, there is a fact in the use of water that has not been touched on prominently, and that is the increased secretion of the skin, the most important of the three great excretory organs, the bowels, kidneys and skin. The bowels may be constipated for three, four or five weeks. I have known myself of a young woman who did not have a movement of her bowels for over three weeks, without any difficulty other than a slight tendency to drowsiness during the day. We are all aware that the entire suppression of the urine will result in death, in the majority of instances, in less than twenty-four hours. I think we are also all aware that the entire suppression of the functions of the skin causes death in the majority of cases within three hours. I think, then, in the use of the cold bath we lose sight of the importance of this, the most important of the three excretory channels.

DR. WEBSTER—May I ask the speaker what evidence there is to support his statement that if the secretion of the skin is suppressed for three hours death ensues?

DR. BORDER—I am not certain that I can recite precisely the experiments that these conclusions are based upon. I think the statement came from Rome, Italy, many years ago, where several small boys, I think 4 or 5 years of age, were covered with gold leaf, and placed in a procession to go around the city for one or two hours. Before the gold leaf could be removed from one apparently healthy child he had died.

DR. STOCKTON—The important matter seems to be the therapeutic use of cold baths in the treatment of fevers, as compared with other methods of treatment. Two years ago, in the meeting of this Section in Milwaukee, this matter of the treatment of typhoid fever by cold water was before the Section, and I for one greatly regretted to see how many men of prominence throughout this country opposed the treatment; 1, because it was inconvenient; 2, because it was unnecessary; and 3, because it was dangerous to their patients. It seems to me that it has been shown to-day that it is unobjectionable, and I think the experience of two years has confirmed the views of those of us who stood for cold bathing.

DR. SUMMERS, N. Y.—I desire to thank Dr. Burr for his ingenious contrivance, which I shall try to avail myself of, and also wish to express the desire that others will speak for the cold bath, so that it may be used in small communities as well as in large hospitals. At that meeting in Milwaukee, you will remember that Dr. Christian Sihler, of Cleveland, spoke of his experience in the use of the cold bath treatment in the houses of the poor in the city.

DR. S. SOLIS-COHEN—I rise to congratulate the reader of the paper upon having made more possible the use of cold water in private houses, in small towns, as was just said. My first experience with the use of water in typhoid fever began when as a student I went through the wards of the German Hospital of Philadelphia, in which the cold bath treatment of typhoid fever was carried out, though not with the rigor of the Brandt method; it was only applied in suitable cases, when thought to be necessary, and not with the thorough system laid down by Brandt. The experiences there gained convinced me thoroughly of the utility of the treatment, and ever since I have been practicing medicine I have used cold water in the treatment of typhoid and other fevers with ever increasing success. Some time ago a student of the University of Pennsylvania, Mr. Boston, devised an apparatus upon the same principle as that shown here to-day, which I tried to employ in two cases. It was not as perfect in its details as this; a heavier rubber was used, because such a sheet as shown here to-day was not possible. The great objection to that, instead of the full bath, seemed to be at variance with the experience related by Dr. Davis. The gathering of a small pool of water around the patient, instead of the full plunge at once into the bath, seemed not to be advantageous, and so, although I have continued to use this device in certain cases where immersion at once into the full bath was not practical, I am fully convinced that it is not equal to it. The reduction of temperature by bathing is only an incident to the treatment; it is the effect, not merely of the abstraction of heat, but of the removal of causes of pathogenic heat production.

DR. TURCK—Not only are we indebted to Dr. Burr for the ingenious contrivance, but also for presenting to this Society the various facts elaborated that are known up to recent times of the effect on the circulation, upon the number of leucocytes, and also the effect that it has in elimination. There is another point to be emphasized, namely, the restora-

tion of the equilibrium of circulation. We are not all dealing with typhoid fever, but how frequently we are dealing with cases of passive congestion of the viscera. When we remember that a few vessels can contain all the blood of the body we can realize how readily this passive congestion can affect the metabolism of the body.

DR. PERTIJOHN—While I commend heartily the explanation of the use of this apparatus, it seems to me a little mixed in the effects that we produce therefrom. If we want to produce lower temperature, the cool water must be continually applied, and the effect produced is not from the cold application, but from the evaporation of the water on the body. So if you pour water on one part and then on another, you heat it unequally, and therefore I maintain that the general sponge bath, or keeping the surface of the body wet for a length of time is very efficacious in cooling the surface. Provided you have congestion of the internal organs, and desire to establish an equilibrium on the surface of the body, the application of cold, like a plunge bath, will at first contract the vasomotor system of the skin, and then the patient will react and the skin become red. So you must produce not only evaporation but an even temperature of cold. If our patients have not a bath tub in their houses, we can do a vast deal toward handling the surface of the body, and the establishment of the surface circulation, by simple continuous sponging. If you want to produce evaporation, put a thin cloth over the body, and sprinkle water over it.

DR. ROCHESTER—I think the last speaker is forgetting what the water is for; it is not simply for reducing the temperature, as was carefully stated by Dr. Burr in his paper. We want to know the tonic effect of the cold bath on the nervous system of the patient; that is the chief effect, and that is the point we should bear in mind. Moreover, as far as the excretions of the skin are concerned, some of the speakers seemed to forget the matter of friction, which is most important. It is not simply the reduction of temperature, but the effect upon the nervous system, and the friction plays a prominent part in this.

DR. JAMES TYSON, of Philadelphia—I want to say that from quite a large experience I feel with others here that every effort should be made by those who have experience to impress upon those to whom it is a somewhat inconvenient measure that under all circumstances, cold bathing should be used in the treatment of fever. The fact that it does give a good deal of inconvenience, and is a severe task upon the attendants and assistants. I think is very decidedly obviated by this apparatus. The use of the bath in the treatment of typhoid fever we do not exactly understand, nor do we understand its exact rationale. It is very interesting to hear from Dr. Burr as to the various explanations of the way in which it may operate. The fact is, however, that although we are all ready to admit that it is not the temperature that we particularly desire to combat, still there is something which goes with the high temperature—whatever it is—and the high temperature is the index, and with its reduction goes the danger from this particular source. I think it is desirable that we should not lose sight of the fact that it is not an invariable cure. I have myself lost cases, particularly those which terminated in perforation and in hemorrhage, which seemed not to have been reached in my experience. I think Brandt says of the treatment, that even in ulceration and hemorrhage, danger is averted if the treatment is begun sufficiently early. This is a fact of importance, which coöperates with what Dr. Burr has said as to using it, even where the diagnosis is uncertain. Therefore, I think if there is any truth in what Brandt says, that we ought not to wait for diagnosis before this treatment is made use of. As to the effects of sponging as contrasted with the cold bath, there is no doubt that the gentleman who last spoke is exactly right in what he says of the effect of evaporation in the cooling of the body, and that in sponging properly to secure this we get the best effects. I have so often contrasted the effects of sponging carried out in the most careful and scientific manner, and the difference between that and the cold bath is so utterly trifling that even nurses say that it is like wasting one's time to administer the sponge bath when the plunge bath is available. If the plunge bath is not available, we should have recourse to sponging.

DR. HOLLISTER—I would like to inquire of Dr. Tyson his experience or his judgment of the use of the bath in scarlet fever.

DR. TYSON—I have no experience.

DR. J. M. ANDERS, Philadelphia—An article such as we have just listened to is certainly most refreshing, because

while rational criticism, which is always allowable, has dominated the clinician in the treatment of typhoid fever in the past, we have to-day an effort made to furnish experimental data to show how the cold bath treatment should be used and how it does good. It is an evidence of the fact that the scientific element of the profession have formed a procession, which is moving steadily in the direction of the treatment of the cause rather than the effect of pathologic processes—an evidence of great progress. It occurs to me that a paper on the subject of the treatment of typhoid by cold baths must be incomplete without reference to contraindications. I do not wish to make any unfavorable criticism upon the paper, as it is impossible to bring out all the points in a single article upon the subject. To my mind, it is highly important, once hemorrhage has occurred, that the Brandt method should be omitted for a time. After hemorrhage has taken place, the danger of its recurrence is made much greater by removal of the patient to the bath.

DR. SYKES, of Ohio—I have listened to the paper with a great deal of interest, and have no doubt that the method carried out is a good one. Physicians who are practicing in small communities, however, can not always get one of these tubs in time, but there is no town where you can not obtain some of the common oil cloth that is used for covering tables. This might be procured and the patient placed on a low, old-fashioned bedstead, and the oil cloth used as a quite effective substitute for Dr. Burr's apparatus.

DR. HOFF, of Ohio—I have treated typhoid fever very successfully, using shower baths and sponging all over the body, also, when necessary, flushing the bowel with cold water injections. I am rather surprised to think that cold water has not been so generally used, because I used it for almost my first case of typhoid fever, some forty years since, and I can recommend it to the profession. It is an old treatment, and a rational one, and something everybody should employ in typhoid fever.

DR. BURR—It is a matter of gratification to me to see the interest taken in the discussion of this paper. It will be impossible to note in detail the comments made for and against this method of treatment. I will refer principally to two or three points. Dr. Davis is right in his opinion about the shortening of the term of typhoid fever. Brandt did not make such a claim for the treatment. The great claim is that it does *modify* the fever in various ways. The systematic carrying out of baths in typhoid fever, begun at an early date changes the whole clinical aspect of the case. Some have claimed that this treatment increases liability to hemorrhage. Liebermeister, who has had experience enough to give him some authority, distinctly controverts that. Out of 861 cases without cold bathing there was 8.4 per cent. of hemorrhages of the intestines; out of 882 with the cold baths the number of hemorrhages was 6.2 per cent.; a difference of 2.2 per cent. in favor of the cold baths. One gentleman does not seem to understand that the reaction is kept up during the whole fifteen minutes by successively emptying and filling the cutaneous blood vessels by gentle friction over the whole body. There would be a great risk in putting the patient in that tub of cold water without friction. Drs. Stockton and Summers referred to a paper read in Milwaukee. I want to say that the paper of Dr. Sihler, of Cleveland, in which he showed that this method was practicable in the poorest of practice, was what inspired me to get up something more convenient to be carried about and used than the ordinary tube. Another thing: with regard to the urine, the patients will frequently urinate in the bath, and keep up an increase in quantity. This treatment is one of the greatest stimulants to the action of the kidneys that can be given.

## IRREGULAR OR ATYPICAL GOUT—HOW SHALL WE KNOW IT?

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY JAMES TYSON, M.D.

PHILADELPHIA, PA.

It has always seemed to me that if the department of medicine as contrasted with surgery is to make advances, it must be by the application of accurate methods. This is equally true of nomenclature as of clinical investigation. In no subject in medicine has there been greater looseness in the application of

terms than in that of gout, and in some recent studies of this interesting subject I have been so impressed with this fact that it occurred to me it might be worth while to attempt to formulate, briefly, criteria by which to judge of the presence of gout in its more irregular forms, with regard to which alone as contrasted with regular or typical gout the confusion really exists.

While many theories have been advanced and many experiments performed with a view to explaining the method of its accumulation, all pathologists agree that the fundamental condition of gout is an excess of uric acid in the blood. The shape in which uric acid exists normally in the blood has commonly been considered to be that of an acid salt, the biurate chiefly of sodium, also the chief constituent of gouty tophi. Recently, Sir Wm. Roberts has attempted to show with apparent success that it is the quadriurate, a salt shown by Bence Jones many years ago to be the principal constituent of the so-called amorphous uric sediment. In this compound, four equivalents of acid are combined with one of soda. It is nearly agreed to, that the local symptoms of gout are the result of an irritation produced by local deposits of the acid salt in the affected tissue. Under certain abnormal conditions the normal quadriurate splits up into biurate and uric acid; the latter being eliminated by the kidneys, while the former remains in the blood until deposited; or the quadriurate may be transformed in the blood into biurate which may be deposited in different parts of the body. But, while uric acid deposits in the joints and elsewhere are commonly the cause of attacks of pain, this is not always the case. Tophaceous deposits are by no means always painful. Hence some, and notably, Pfeifer who has lately done much experimental work bearing on the subject believes it is the uric acid in solution and not when deposited which causes the attack of gout.

In true or typical gout we have a definite morbid state, the tendency to which is commonly inherited, but which may also be acquired, and corresponding to this set of definite symptoms. These may also manifest themselves in an irregular manner and degree, constituting the irregular forms of gout. Among these, however, are constantly being included complexes of symptoms which are erroneously ascribed to gout, and it is with a view to point out and discourage such erroneous association that I have written the present paper.

It is more particularly irregular gout, under which are included certain ailments not legitimately ascribable to it. This is not surprising when it is remembered that there is scarcely a form of visceral or external pain, functional or organic derangement which has not been by some one or other declared to be gouty in origin—often, indeed, with reason and propriety. It becomes, therefore, extremely important that we should elect some data on which to base a decision, and the more so since gout is growing in frequency in this country.

First as to irregular gout whose existence has been acknowledged by all authorities on gout from the time of Sydenham down to the present day. What is it? A leading authority of the present day, perhaps the leading authority, Sir Dyce Duckworth says: "Gout manifesting itself anywhere but in a joint is to be considered irregular or incomplete." He says further: "Such phases of the disease may be anom-

alous, but they are very common, and as such are so far regular as to comprehend a number of ailments which pertain chiefly and in some cases exclusively to persons of gouty heritage and diathesis." Also: "Without doubt many morbid states have often been flippantly or erroneously set down to irregular gout which own no such designation, and thus a cloak for ignorance has always been at hand to throw over careless observation, ignorance or willful misinterpretation of symptoms." Both sentences last quoted sound very well, but when we attempt to look up the number of ailments "which pertain chiefly and in some cases exclusively to persons of gouty heritage and diathesis" they are hard to find, especially when we are informed by the same authority that the absence of tophaceous deposits, or of the history of an attack in a big toe, or of heredity, or of personal history, calculated to promote gout, does not necessarily exclude the ailments from the category of gout. And further "that it is just in cases where no marked coarse objective signs of gout exist that we should look for the presence of the minor tokens of the affection, and just in such cases that we commonly find them." These statements are so contradictory that it is plain that nothing can be deduced from them. I propose briefly to point out certain conditions under which ailments may be legitimately regarded as gouty, and though ailments truly gouty may sometimes be excluded by reason of absence of such conditions these must be very few. It is to be remembered that we are speaking of irregular gout, for regular gout is easily recognized by definite symptoms which it is not my purpose to allude to.

It is in place, however, to name some of these ailments. They include first in the words of another acknowledged modern authority on gout, Sir Prescott Hewitt: "Dyspepsia, more or less troublesome; frequent deposits of lithates; slight eczematous eruptions from time to time; anomalous pains in various muscles; sharp deep-seated pain in the tongue, existing for two or three days and then disappearing altogether for a while; crackling about the cervical spine on slight movements, more or less; sometimes a mere suspicion of knottiness about the smaller joints of the fingers." The muscular pains may be anywhere and "flying" in nature, but the muscles of the back of the neck, the lumbar muscles, the adductors of the thigh and gastrocnemii are especially liable. The pains are apt to come on in the night and are bad in the morning on awaking, but improve as the day advances. In addition may be mentioned articular pain, nodosities and deformities about the finger joints of other than tophaceous composition. From these are to be excluded, except in very rare instances, Heberden's nodosities which are not usually of gouty origin but belong to rheumatoid arthritis which is distinctly not a form of gout—although unfortunately also called rheumatic gout. Among them are, however, certain vesicular eminences on top of Heberden's nodosities described by Paget and Garrod.

In the same category are included headache of every variety including migraine; tingling and pain in the palms of the hands and soles of the feet and heels, and tendo-Achillis; also follicular inflammation especially about the end of the nose, scleritis, keratitis and conjunctivitis with white spots (tophaceous) in the cornea and eyelids. Asthma, bronchitis, tonsillitis and pharyngitis, dryness of the mouth and tongue are considered the result of gout. Then there

are the various skin affections, also gastric pain, flatulent colic, urethritis, orchitis, prostatitis and cystitis with hemorrhage into the bladder in men, and ovaritis, metritis, dysmenorrhea in women, as well as meningitis, neuritis, endarteritis and the whole category of affections known as visceral and retrocedent or metastatic gout, including gout of the stomach and heart and cerebral gout or *apoplexia arthritica*. Various psychopathia including irritability of temper and capriciousness, especially melancholia with suicidal tendency, insomnia—all of these are at times of gouty origin. In fact, as already stated, there is scarcely a single ailment which has not been ascribed to gout. I will only allude further in this place to one of these symptoms of undoubted gouty origin the nature of which is often overlooked and that is hemorrhage into the bladder. I have known a medical man given up by his attendants as hopelessly ill from malignant disease of the bladder, which was filled with blood, simply the result of gouty hemorrhage, as proved by autopsy several years later.

In view of these facts, does it not seem necessary to establish some criteria whence we may judge whether the ailments mentioned which so evidently arise from many causes, are due to gout or not? Casting about for such, it has seemed to me that the following conditions may at least serve as a guide to aid one in determining the etiologic relations inquired after:

It is plain, first of all, that if uricacidemia can be demonstrated to be present it may be regarded as strong presumptive evidence that any one of these events is gouty. Unfortunately it is rarely possible to test this fundamental condition of gout, because of the want of the special skill and apparatus necessary for the purpose. For it is to be remembered that uric acid deposits in the urine are no criterion of the quantity of uric acid in the blood. This can only be determined by blood analysis.

2. The supervention of an attack of regular gout simultaneously with subsidence of some one of the ailments named, or an alternation of any one of these with regular gout. This is one of the most valuable criteria, which may be regarded as almost conclusive, let the ailment be almost what it may. One need not go far to find many remarkable instances.

3. The history of previous attacks of regular gout. This must be taken in connection with the absence or presence of other causes capable of producing the same ailment.

4. The presence of traceable hereditary tendency to gout. This has a value similar to the preceding, and must be similarly considered.

5. The history of exposure to lead poisoning or other symptoms of plumbism. The association of plumbism with gout or saturnine gout as it is called, is one of the most interesting features in the history of gout. It is undoubted although the frequency varies greatly in different countries. Thus in France, Germany, Ireland and Scotland it is rare, while in England, especially in London, it is common.

6. The history of a habit or mode of life which furnishes the conditions of acquired gout.

7. The constant presence of a high-colored scanty urine of high specific gravity with a tendency to lateritious sediments and uric acid gravel. It does not often happen that gout and gravel coexist. More frequently they alternate, the passage of gravel ceasing with the appearance of gout, and *vice versa*, and

the supervention of any of the ailments named on an attack of uric acid gravel makes it seem reasonable that such ailment may be of gouty nature.

Now it is well known that these phenomena of lateritious sediments and scanty urine are a part of the lithemic state, and the question of the relation of gout to lithemia suggests itself at this point. It is also well known that in addition to the characteristics of the urine just mentioned there is a commonness of other symptoms. The headache, migraine, depression of spirits, shooting pains, cramps, palpitation and vertigo which characterize gout are a part of the symptomatology of lithemia. Nay, more; the same causes which lead to one lead to the other. Free living in the broadest sense of the term, including the luxury of habit which is associated with the possession of wealth, is the cause of both, but while a similar train of symptoms exists in both the resemblance stops at the joint affection. In lithemia there are no tophaceous deposits. If there are, the lithemia has become gout, an event which sometimes comes to pass. Why is it then that one man acquires lithemia and another gout under the same mode of living? The answer, it seems to me, must be that the lithemic person is not really gouty; that is, does not possess the inherent tendency which favors the development of gout. It is well known that lithemia is a common disease among Americans while the English of all people are most subject to gout. The American, as a rule, is not yet gouty. On the other hand, the American is rapidly becoming gouty. I find the number of gouty cases in my own practice increasing, and they include the grand-children and children of those who have not been gouty, but who were poor and had to work hard. I also find among them the children of families where there has been gout, but where it has been kept in abeyance for a generation or more by the same causes.

8. The presence of glycosuria in association with gout, or in alternation with it, or in certain members of gouty families is an undoubted fact, and establishes a very close relation between these two conditions. I have nothing to do here with the question as to whether such glycosuria should be called true diabetes mellitus or not. It may be mentioned, however, in passing that the cardinal symptoms of diabetes, thirst and polyuria are often wanting and that such cases of glycosuria are the easiest of all to control. Such glycosuria may alternate with uric acid sediments or may be associated with them, and its presence should always suggest a suspicion of gouty nature to a concurrent or alternating ailment.

To a much less degree the presence of chronic interstitial nephritis, which I believe is always sooner or later the fate of the victim of gout, should also receive consideration.

10. Finally, here as in so many other cases, therapeutics comes into play as a factor in determining the nature of an ailment. Should such be relieved by the typical treatment for a gouty paroxysm, its gouty nature may be regarded as established.

Thus it will be seen that there are a number of data which may help us to a correct diagnosis, and that random guesses are not necessary in the majority of cases. It is true that a conclusion can not always be arrived at with promptness, and a careful and even prolonged study may be necessary before such conclusion is justified, but I hold that in the

vast majority of instances it can be made, and that there is no excuse for the carelessness so often practiced.

## DISCUSSION.

DR. ANDERS—I can not forbear saying a few words on an interesting paper like Dr. Tyson's. What I wish particularly to call attention to is the fact that Dr. Tyson has distinguished clearly between what has been called since Richardson's time, latent gout or lithemia. I am particularly pleased to hear that differentiation made, and I do not think it can be made too often. I would go a little further, and say that I do not think that lithemia necessarily leads to gout at all. That we have the uric acid state in lithemia is undoubted, and that we have the symptoms that closely resemble gout is undoubted, but that there is any distinct relation between the two in the matter of tendency I have great doubt. The diagnosis can, I believe, be made from lithemia without much difficulty.

DR. HERRICK, of Cleveland—I have enjoyed the paper very much. Barber has published a work in which he indulges in very nearly the same view. I also rise to the point of the terminology of the disease. It should not be regarded as atypical. Gout is a term not expressive of any particular phase of trouble. What we desire to express is the departure from the normal, and also looking to its source. The author to whom I refer speaks of its source as the digestive tract. I think we will all agree in the opinion that the disease is one referable to disturbance of the digestive tract, or to excesses of food, or general hygienic conditions of that character; deficiency of exercise, with much indulgence in nitrogenous food and alcoholics. It seems to me that we have large hopes in the line of investigation of this class of difficulties, because as the paper says, there are multiple evidences affecting different parts of the body.

DR. ANDERS—I rise to obtain information from Dr. Tyson. It was mentioned by him that one of the main factors for diagnosis was the history of heredity, and in that I fully concur. I have also observed that gout is markedly hereditary in the families of the poor as well as in those in the opposite condition of life. My observation teaches that it is much more hereditary through the female than the male, and in this I am not alone. I should like to hear an opinion on this point from one who has seen so much of gout as Dr. Tyson.

DR. TYSON—In answer to Dr. Anders, I may say that while I am aware of what he says, and agree with the authorities in regard to the heredity of gout through the female, I can not in my whole experience add anything to the knowledge on the subject. As to the kinship between rheumatism and gout, I tried to avoid that question, except from this standpoint: one of the facts that we have most frequently to contend with is that rheumatism is called gout a great deal more frequently than it should be. My idea in forming criteria was partly in order to know whether certain cases are rheumatism or gout. The symptoms of acute gout and the symptoms of rheumatism are widely different. In chronic gout we have a lack of similarity in certain symptoms, and I feel that enough care is not exercised by physicians in this particular.

THE CHAIR—I should like to ask whether there are not certain cases in which it is impossible to make the distinction between rheumatism and gout?

DR. TYSON—There are cases in which it is extremely difficult if not impossible to decide. The only point is that we may decide with care more frequently than we ordinarily do.

DR. ANDERS—I should like to ask Dr. Tyson whether he considers rheumatism an infectious disease?

DR. TYSON—Yes, I regard acute articular rheumatism as infectious.

## THE CONDITION OF THE TWO VENTRICLES WITH REFERENCE TO THE ADMINIS- TRATION OF DIGITALIS.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY ROBERT H. BABCOCK, A.M., M.D.

PROFESSOR OF CLINICAL MEDICINE AND DISEASES OF THE CHEST,  
COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO, ILL.; AT-  
TENDING PHYSICIAN COOK COUNTY HOSPITAL.  
CHICAGO.

The commonly accepted indication for the admin-

istration of digitalis is cardiac weakness in its broadest sense. More precisely drawn this indication is furnished by weak, rapid, perhaps irregular action of the heart, low pulse tension, a mitral murmur indicating regurgitation or stenosis, dilatation of the right ventricle with or without leakage of tricuspid valves, and dropsy. Cardiac dilatation without valvular disease is also considered to indicate digitalis. Whatever differences may exist in the cardiac conditions, there is always present relative arterial anemia with venous hyperemia. Yet that something else beside mere cardiac weakness exists upon which may depend the usefulness or injury of digitalis is illustrated by the following case:

Case 1.—Oct. 29, 1894, A. D., male, age 12, was seen in consultation. It was a typical case of mitral insufficiency with lost compensation. Hyperdicrotism of the pulse as shown by the sphygmograph, great dilatation of all the cardiac chambers, particularly of the right ventricle, mitral systolic murmur and the classical signs of tricuspid leakage, with greatly enlarged and pulsating liver, ascites and considerable edema of the lower extremities, great pulmonary congestion and moderate hydrothorax in the right pleural cavity. Two examinations of the urine subsequently revealed a few granular casts, 1 per cent. of urea and slight albumin. Diuretin-Knoll and a brisk purge removed anasarca and greatly lessened the ascites within the next two or three days. The hyperdicrotism and the manifold signs of pulmonary and venous congestion seemed to plainly indicate cardiac tonics. Convallamarin one twenty-fifth of a grain, t.i.d., was ordered. No improvement resulting after two days, the condition on the contrary seeming rather worse, a fresh infusion of digitalis (U.S.P.) was made from English leaves by one of the most reliable druggists of Chicago. Of this infusion 1 drachm was given every six hours for three or four days. The pulse grew progressively smaller and more hyperdicrotic if that were possible, while the cardiac impulse became more diffused and feeble but not irregular. Strophanthin one hundredth of a grain was then ordered and given for about twenty-four hours. Then came one evening two alarming sinking spells which necessitated the free use of stimulants. At this time the enormously dilated right ventricle, could be felt, feebly pulsating in the intercostal spaces to the right of the sternum, and the sounds at this point took on the rhythm of the *bruit de galop*. The urine had progressively diminished to about eighteen ounces in the twenty-four hours. The patient's condition was truly alarming and we realized the necessity of resorting to urgent measures. Strophanthin and digitalis had not only proved useless but apparently injurious; accordingly nitrate of strychnia, one-fiftieth of a grain was ordered, subcutaneously every four hours, alternating with one minim of a 1 per cent. solution of nitro-glycerin every four hours and 2 drachms of whisky three times a day. A hydragogue cathartic was also administered. The next day to our astonishment the pulse had fallen from 122 to 92 and was perceptibly fuller and less hyperdicrotic. The galop rhythm over the right ventricle had disappeared as well as the pulsation in the jugulars. Improvement was steady and ten days or two weeks subsequently, 1 drachm of digitalis infusion, together with moderate doses of diuretin-Knoll, t.i.d., was well borne and caused removal of the ascites and edema, the urine increasing to one hundred and twelve ounces per diem. The subsequent history of this case does not call for recital here.

Here was a case in which all conditions laid down by Bartholow for the administration of foxglove were present, and yet it was manifest that had the digitalis been pushed the patient would have succumbed. It can hardly be urged in explanation that the infusion was inert since it was made out of English leaves. To what then was the failure of this drug to be attributed? Before attempting to answer this query permit the brief recital of a second case:

Case 2.—Dr. E., male, something over 50 years of age, physician, was seen in consultation last January. The chief complaint was of frequent and harassing dry cough, with dyspnea and rapid feeble pulse on slight exertion. To make a long story short, suffice it to say, there were found moderate dilatation of the left ventricle; first sound being feeble, sec-

and pulmonary sound greatly accented, recent pleuritic adhesions at the base of the left lung, moderate congestion of liver and kidneys, no râles or distinct physical signs of hypostatic congestion of the lungs. Peripheral arteries showed slight thickening; urinalysis by Dr. C. W. Purdy had revealed the existence of chronic interstitial nephritis of moderate severity. The harassing cough and dyspnea were attributed to weakness and dilatation of the left ventricle with consequent pulmonary congestion. This case seemed preëminently one indicating digitalis. A fresh carefully prepared infusion was ordered therefore and taken in 3 drachm doses, t.i.d. The urine increased in amount, pulmonary congestion diminished and the cough was entirely relieved.

Here, then, was a case in which the drug displayed its happiest effects. Wherein did the difference in these two cases exist, so far as referred to the administration of digitalis?

If one will search authorities, both in materia medica and therapeutics, as well as in clinical medicine it will be noticed that, with but very few exceptions, no reference is made to the action of digitalis on the right and left ventricle respectively. It seems to be taken for granted that its action on these two chambers is the same. That this may not be the case was first suggested to me by some statements made by Openchowski in his discussion of Leyden's paper, "*Ueber die Prognose der Herzkrankheiten.*"<sup>1</sup> This led me to search out Openchowski's original communication,<sup>2</sup> wherein is published the account of his experiments with digitalis. As a preliminary work, he first investigated the effect of vasomotor dilators, as amyl-nitrite, on the pulmonary vessels and determined that they were wholly without influence on this system. Tension within the pulmonary artery became increased secondarily as a result of lowering of the blood pressure within the aortic system. By means of the kymograph he found that small doses of helleborin failed to increase blood pressure within the pulmonary artery or right ventricle. In fact, the pressure fell somewhat at the beginning of the experiment. He observed furthermore that if injections of helleborin and digitalis were given and the living heart then excised and immersed in a weak salt solution, the left ventricle continued to beat long after the right had ceased, the reverse of what happens in hearts not poisoned with these agents. Moreover, in animals killed by these poisons the left ventricle was found post-mortem firmly contracted, while the right was relaxed. Upon exposure of the heart in the living animal, previously poisoned by digitalis, the left ventricle was seen to beat more slowly and three or four times as long as the right. The left coronary artery was distended with blood and small ecchymoses were found in the myocardium of the left ventricle; whereas the right coronaries not only were not distended but seemed somewhat smaller in volume, and no ecchymoses were ever discovered in the area of distribution of this vessel. He explained the production of these ecchymoses by the pressure brought to bear on the turgid vessels by the strongly contracted myocardium. The reaction of the coronary arteries to digitalis was similar to the effect observed by Lukianoff, of ligation of these vessels. Constriction of the right was followed by turgescence of the left, whereas dilatation of the right did not follow ligation of the left.

Openchowski concludes, therefore, that the coronary

arteries possess an eliminating or regulating influence over the action of digitalis on the right ventricle. He thinks this conclusion borne out by clinical experience; that is, by the observation, that in case of disease of the right coronary artery, the effect of digitalis on the right ventricle is injurious. He cites in support of this statement a case of mitral stenosis in his own ward in which dyspnea and death followed a few small doses of digitalis and in which the right coronary was found atheromatous after death. In referring to his experiments and conclusions in the discussion of Leyden's paper above cited, he mentions also that A. Fraenkel has published three cases of mitral stenosis, in which the administration of digitalis was promptly followed by dyspnea and cardiac failure. I regret to say I have been unable to get access to this paper of Fraenkel. I have, however, carefully perused an address by Leyden,<sup>3</sup> to which Openchowski alludes, and find he says essentially as follows: "The beneficial effect of digitalis in cases of mitral disease would seem to point to its chief action being on the right ventricle, but as other experience seems to warrant an opposite conclusion, this matter will have to be left undecided. Although this remedy may be indicated and often beneficial in hypertrophy and dilatation of the right ventricle in mitral disease, it is often useless when this condition of the ventricle depends upon chronic bronchitis and emphysema or kypho-scoliosis with dyspnea and dropsy. So that, as Leyden says, the right ventricle seems to acquire but little energy from digitalis on account perhaps of the small volume of its myocardium."

In this connection may be cited the experiments of M. Heger reported in *Bulletin de l'Académie Royale de Médecine de Belgique*, and of which a resumé may be found in the *American Journal of Medical Sciences* and the *Therapeutic Gazette*, 1892. This experimenter concluded that the action of digitalis was exerted chiefly on the left ventricle and aortic system; that its effect upon the right ventricle was similar but much less powerful; that it exerted no direct influence upon the pulmonary vessels, but it was capable of relieving stasis within the pulmonic system through its action on the left ventricle. He likened this action therefore to a veritable bleeding from the lung. It will thus be seen that although Heger considers digitalis to exert more influence upon the right ventricle than does Openchowski, he agrees with the latter in finding no direct action upon the pulmonic system and the effect on the right ventricle subordinate to that on the left.

Whether or not Openchowski has proved experimentally all he claims concerning the action of foxglove, there seems to be clinical evidence sufficient in the opinion of such men as Leyden and Fraenkel to render doubtful its utility in all cases of dilatation of the right heart. To return now to the case of the lad described above. All the recognized indications for digitalis were present and yet it was manifest at the time that this and kindred remedies did harm. It is not easy to explain why this was so. Disease of the right coronary artery with consequent inability to regulate the drug's action on the myocardium, was not likely in a boy of 12 years. There was enlargement of the left ventricle and, so far as I could determine, this enlargement was due to hypertrophy rather than dilatation although this latter condition

<sup>3</sup> Über die Wirkungsweise und die indicationen der digitalis. E. Leyden, Deutsche Med. Wochenschr., Berlin 1881, VII, 345, 358.

undoubtedly existed. There was an evident disproportion between the strength of the two ventricles in favor of the left, the right being in a state of extreme dilatation. Moreover there was free regurgitation through the incompetent mitral valves. When digitalis was administered its effect, if we may trust the results of experiments, fell chiefly on the stronger of the two chambers. Its contractions were strengthened as could be determined by the pounding impulse against the chest wall, while their rate was but slightly diminished.

The failure of the drug might be theoretically explained as follows: instead of discharging a larger volume of blood into the aortic system, as should have been done, the ventricle may have emptied the larger part of its contents through the wide open mitral orifice; therefore, instead of aspirating the blood out of the over-loaded pulmonic system, the ventricle threw back again the increased volume which had accumulated within it during its somewhat lengthened diastole. The dilated and feeble left auricle could not withstand the shock which consequently must have fallen upon the right ventricle. Distension of this latter was promoted rather than decreased.

However the failure of digitalis in this case may be explained, its effect plainly corroborates the position taken by M. Huchard, who declares that excessive dilatation of the heart furnishes a contra-indication to the administration of digitalis. He advises first the withdrawal by venesection of from eight to ten ounces of blood, which will remove the over-distension of the organ.

In my case a purge was administered in addition to nitro-glycerin and strychnin. The result was the accomplishment of just what had failed to be done by the digitalis.

In the second case described above, the left ventricle was the chief seat of weakness but the mitral valves were competent. Here the drug lengthened diastole, thus permitting a better filling of the ventricle and energized its contractions. Blood was aspirated, as it were, out of the lungs into and through the left ventricle into the aortic system. Hence the action of digitalis was displayed in its perfection. Could anything be more striking than the difference in these two cases?

Whether or not the *modus operandi* in the first case has been properly explained, that is, whether or not the failure of the digitalis can be ascribed to any of the reasons laid down by Openchowski and Heger, or to the theoretical explanation I have given, the case furnishes clinical evidence that digitalis may fail to favorably affect the right ventricle in cases in which it most urgently demands a tonic. To my mind it furnishes a strong degree of clinical proof that the administration of this drug and its congeners depends for its indications upon the relative condition of the two ventricles. It is not assumed for a moment that these two cases settle this question; it is only hoped that the recital of these cases and the reference to Openchowski's work may open up a line of discussion in this meeting and a path of clinical investigation which will prove of future value.

## CARDIAC INSTABILITY DUE TO ACID AUTO-INTOXICATION.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY W. T. ENGLISH, A.M., M.D.

PROFESSOR PHYSICAL DIAGNOSIS IN MEDICAL DEPARTMENT OF THE WESTERN UNIVERSITY OF PENNSYLVANIA; AND CONSULTANT IN CHEST DISEASES IN THE SOUTH SIDE HOSPITAL, PITTSBURG, PA.

The study of the phenomena occurring in the human body would be attended with vague and impenetrable mystery were it not that we know something of chemic affinities and aversions. A great deal of the light that has recently illuminated the medical realm is reflected from the chemic laboratory. Chemistry and microscopy have been extending their arms of light in the attitude of a prolonged benediction over our science for at least a decade. No methods of investigation have merited and received such universal adoption. The only cases that can now be admitted to an audience with the advanced physician without contact with reagents or microscopic scrutiny are hypothetical ones. The man who is satisfied with the dictum of his unaided eyes, ears and sense of touch in physical examinations is behind the procession. These methods of inquiry introduce us into the arena of vital action, and make plain to our understanding the pathologic processes. Much that has hitherto been attributed to diathesis and temperament finds explanation through the medium of study associated with changes that are chemical and molecular. Instability in bodily life appears in harmony with the rule that the more complex the molecule the more varied the incidents associated with its activities. The somatic functions are known to be subservient to molecular caprice. The molecule being dominated by chemic affinities and aversions the demeanor of individual parts and organs is correspondingly inconstant. Invariably nature varies. This unstable demeanor of the chemic equivalents brings the pathologic line very near to the normal. So that, if to-day the citadel of life is besieged by the acid forces, to-morrow every fort may be dominated by the bases and salts. Through the infinite window of the microscope we may now observe the aerobic bacterium dignitary felicitous in his oxygen bath—and anon he will be seen wallowing in the filth and excrement of the anærobic laggard. Under one administration the aristocratic white corpuscles dance along the epithelial sidewalks of the arterioles, and under another they are displaced by their ruby democratic constituents. All this may obtain because of the change of control taking place between the acids and the alkalies.

Many facts have been observed in the recent past, by means of the acids referred to, which demonstrate clearly the presence of chemic forces in the production of otherwise unsolved mysteries, and these can not longer be ignored. Numerous insidious, but, nevertheless potent changes, continuously going on within the economy, can be accounted for only by the traffic in acidulous elements. There have been repeated and tangible evidences, in my experience, of abnormal heart phenomena that have linked them inseparably to acidulous conditions, as betrayed by lowered alkalescence of the blood, and what is equivalent thereto—hyperacidity of the other bodily fluids. Few of us have not had startling and hapless results from unsuspected heart malady

which were not accounted for by conditions present, or by any antecedent causes, so far as we could determine. After investigating in this realm a number of cases of cardiac instability, I have convinced myself that the mal-behavior and myocardial deterioration are sequelæ to a prolonged acid auto-intoxication.

It is almost universally admitted that a large excretion of acids is contemporaneous with an irritable condition of the heart and circulatory apparatus. The presence of much acidity, no matter how produced, always and persistently coexists with this state of the circulation. Theoretical and chemic testimony are corroborative, and investigations have sustained the assumption in nearly every case. After prolonged mal-behavior superinduced by acid conditions the heart shows weariness. And if theoretical and chemic proofs were wanting, this empirical evidence—that acid conditions may induce nutritive lesions in the myocardium—can not be successfully denied. Symptoms of intermittence of impulse rapidly pass from the neurosal into the organic form. If the cases continue there follow the results commonly found in similar conditions of the heart from dissimilar causes, viz., dilatation from myocardial changes and inefficiency of the valves from peripheral traction; or in other words, relative or muscular incompetency. We have not far to seek for authority to prove that acid impressions extend beyond the nerve influences and when toxic, even in a slight degree, the symptoms appear as involving the regular action and accustomed functionation of organs—especially the heart; for it is well known that all troubles which involve a waste in the residual nerve force entail marked depression that leads to disintegration. Doubtless we have all observed the influence of acid conditions brought about by dyspepsia and the coincident tumultuous behavior of the heart. We may not have attributed these symptoms to the direct irritation of the acidulous blood upon the heart, yet all have recognized the symptom.

Chemic combinations of the blood are known to play a great and important part in the action of the heart, probably in two ways: 1, by direct disturbance of the sub-endocardial ganglia; and the endocardium in close relation to these ganglia; and, 2, by irritation directly conveyed through the coronary arteries and their branches to those ganglia situated in the muscular tissue. The presence of irritating materials in the blood does not specifically limit its pernicious influence, but it prevents proper elaboration and metabolism. In addition to this, it crowds out the material most needed for cardiac nourishment, which influence has its first and most natural expression through the trophic nerves and ganglionic cells. Although in early stages this condition is curable, if long neglected it is followed by an ingravescent asthenia, from which there is no recovery.

So much is now known of the influence of acids upon the heart that we are sure they first exhilarate, then shorten the duration of the systole and subsequently render it less and less powerful until contractions cease altogether and the ventricle remains at rest in diastole. When introduced gradually, and their presence protracted, there is a gradual degree of tolerance cultivated which masks the results somewhat.

Acids influence the entire circulatory apparatus

through the nerve supply. Vasomotor effects are extremely liable to betray themselves in the periphery by cold extremities and chilliness of the surface. Reduced alkalinity causes contraction of all the arterioles in the body and may induce spasm of certain areas. Contraction of these vessels is so universal, and the cold surface and extremities so constant, that high tension is to be supposed whenever the degree of acid auto-intoxication is reached. High pulse tension has been produced at will by several experimenters, by foods, medicines and drugs that were known to influence the acidity or alkalinity of the bodily fluids. When high pulse tension and confusion in the nerve supply of the heart coexist, there is a want of adaptation of the central organ to the circulation throughout, and a season of confusion follows, during which there is an increased demand upon the heart for systolic force and a lessened capacity for its achievement. In addition to the mal-behavior superinduced in the heart by the ceaseless traffic in blood of lowered alkalescence, it meets with considerable and effective opposition in the spasmotic demeanor of the pulmonary arterioles. The heart encounters its most deplorable opposition in the pulmonary apparatus. Pulse tension thus influenced in the presence of any renal disability would surely be followed by albuminuria and nephritis. If the heart is deprived of the aid of these emunctories the acid tide rises, the cardiac muscle grows weary, and dropsies, nervous accidents, headaches, dyspnea, etc., supervene.

The acids taken into the body and others which are the products of chemic changes within the body are constantly passing out of it through the lungs, skin and kidneys. Complete oxidation is essential to a perfect balance, but, from the very nature of things this can never be. The organs and tissues act as dialyzers, and, as far as they have the capacity, they set about to neutralize the superfluous acidity. If the liver is flooded with acid it may elect to store it up until a more or less remote opportunity for elimination arrives, or it may cause it to assume some other chemic state. The spleen has accorded to it similar capacities. The kidneys and skin soon divest themselves of its irritating presence. The stomach and digestive tube decompose it and pass it along to other parts, with more or less celerity; or expel it as gas, vomit or fermentative stools. But the heart is minus such function and is constantly subjected to its irritative influence without means of defense. Acidity, which is produced from neutral salts, as frequently occurs after dialysis, may have immediate contact with the heart and circulation.

The acids which are introduced into the system in foods constitute a very tedious list. Those which are met with as natural or normal elements in the various processes of nutrition are similarly extended. When the digestive tract is converted into a fermenting apparatus other combinations are formed, and their number and variety are vastly augmented. When acids appear in the free state in the system they are found in the urine unchanged. There is a hypersecretion of hydrochloric acid that may contribute to over-acidity, and a similar result obtains in an indirect way by too small a quantity, which will permit fermentation.

Much animal food favors acidity on account of its large contribution of acid salts. Beer, ale and light wines conduce to acid conditions.

It is assumed that the liver stores up uric acid. From thence it is conveyed to the kidneys, and there is only a partial excretion and this admits of an overflow by the renal veins causing its appearance, to a small extent, in the general circulation. Thus it gains entrance to all the organs. It is shown that in cartilages and joint tissues, and also in the bony structures, acid is stored. These parts being less vascular than most portions of the body, acid deposits are not rapidly removed, even after the blood alkalinescence is recovered. But the presence of nodosities and deposits of this kind, pre-supposes a condition of high acidity in itself. The line may extend, in those of exceedingly acid dispositions, beyond the uric acid mark.

Special stress is laid by some upon sarcolactic acid. This is formed by muscular exertion, and at the same time there is deposited carbonic acid.

With all these channels through which the blood may reduce its alkalinity and the body become an acid storehouse, it is not to be wondered at that there is a probability of acid auto-intoxication at any time. But if it so happen that excessive formation and defective elimination appear at the same time, the difficulties would become apparent.

Defective elimination of the acids may be due to diseased condition of the lungs, skin and kidneys, or possibly to want of physiologic stimulus to the exercise of their functions. Acid exaltation follows every temporary suppression of the emunctories, and this is accompanied by decline of blood alkalinescence.

Very slight impressions made upon an individual by his environments will exert modifying influences. The temperature of surroundings deserves consideration. A hot room promotes perspiration and diminishes acidity. Conversely, cold and damp diminish excretion and raise the acid line. By this suppression of the perspiration in those of low alkalinescence of the blood there will follow irregular heart action, intermittence of the pulse, increased peripheral resistance and elevated blood tension, accompanied by dimness of vision, vertigo and numbness of the extremities. These symptoms may come on insidiously but oftener are very precipitate, as in the presence of all the various means by which the acid tides in the body rise. It must of course be known that there is a constant ebb and flow with most if not all. However, there are some persons who live just upon the acid line and everything not decidedly alkaline will force them into the acid realm. There is a distinct nocturnal acid tide period. High acidity during sleep is the rule. There is a diurnal tide rise beginning about 3 P.M., and continuing until 5:30 or 6 P.M. These are free from changes incident to ingestion of foods and are, in the major part, of alkaline influence.

There is no doubt that the recurrence of these acid tides and continuous exposure to their influence imparts to the tissues an aptitude to take on inflammatory conditions, and incline toward perverseness of nutrition, from which tissue change and fragility may reasonably be expected and do arise.

In passing, it may be well to note that the period at which the most lamentable accidents in heart lesions occur, corresponds to the hours when the acid tide is at its highest, viz., during the quiet of the night. This is the season when the circulation should be reposeful, and yet it is in a great many cases, the time most prolific of cardiac anguish. This acid tide

rise corresponds to sudden deaths which occur without suspicion of heart malady. It also gives a rational explanation for some others which have been regarded as inscrutable acts of Providence. Let us review briefly, a typical case of heart change due to acid auto-intoxication, in that most gradual process which would include the entire life of the individual:

We will assume that the blood at birth flows purely alkaline. During the first twenty-four hours after birth nothing occurs to disturb this condition, even the alimentary canal is free from fermentative actions and reactions. From this time onward, numerous infinitesimal vegetations begin their perilous work in the *prima via*. Bacteria, ptomaines, etc., henceforth continue their merciless crusades. The tissues and fluids take on the acidulous character in consequence of the presence of acid in the body. And thus the never-ceasing cycle of acid activity is begun.

Hydrochloric, lactic, acetic, butyric, sarcolactic and other acids struggle toward the emunctory outlets. The excretions are all acid. Some extraneous influences ever and anon suppress the functions of the skin and there is a coincident acid rise. The heart makes its first misstep—it has been guilty of an intermission. Amid the acid ebb and flow, and varying stress incident thereto, the child heart must respond to the unceasing demand for development, so that at the end of two years it may have doubled its bulk, and at each quinquennial thereafter redouble it until it has arrived at the period of bodily maturity. Meanwhile new features and strange processes are inaugurated, including those important changes incident to puberty and adolescence. Together with an over-consciousness of a generous nerve supply is vouchsafed a vasomotor and circulatory system rendered specially sensitive because of the constancy of the lowered alkalinescence of the blood traversing it. For a time the circulation is spurred onward and the vital activities are pushed to their zenith point. In such a subject, plethora is extremely liable to come on early. The subject finds himself a slave to his cravings for foods and drinks with scarcely enough will to resist the simplest demands. In consequence he is prone to supply material for oxidation so freely, by over-feeding, that the contribution of oxygen is inefficient to secure complete combustion. Because acid elimination occurs at every point, there is a constant desire for fluids and foods to replace the acid output. Acids are freely ingested, and acid foods preferred. The emunctories are overworked and lag in their energies. About this time in the progress of acid auto-intoxication the subject's feelings trace for him, a diurnal curve in his bodily acidity, and the heart is very commonly in a tumult.

The constant and protracted irritation of the intrinsic cardiac nerve supply and the vasomotor excitement produce general mal behavior of the circulatory apparatus. It appears as a purely nervous phenomenon, but close analysis will give it a different interpretation. The respiratory limitations are becoming more and more evident. Especially is dyspnea noticeable when the ingestion of acid and gas producing foods combine mechanical obstruction with demands for large oxidation. The heart now yields, in these paroxysms, the stethoscopic and physical signs of weakened myocardium, and is on the verge of valvular inefficiency from peripheral traction.

The prognosis is that some day there will be a call

at the patient's door to which he will not respond, or may be, that surrounded by a social circle his eyes will suddenly lose their luster, his tongue forget its cunning, and he will thrust into their experience the deplorable, foudroyant and overwhelming sequence of cardiac changes due to acid auto-intoxication.

The corollary conclusion is that acids should not be employed freely or promiscuously in our foods and drinks. That in most cases they act as irritants to the circulatory apparatus. This fact is especially to be noted in cases of heart weakness or circulatory lesions. The principal demand upon the physician is that of oversight of the ingesta. Numerous cases will demand the employment of alkalies and antiseptics to overcome acidity and fermentation.

### THERAPEUTICS OF THE SENILE HEART.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.
